# Chapter 1

# Library Postscript

# 1.1 Postscript

## 1.2 Looking back...

- Functional programming "declarative" programming (recursion over persistent data structures)
  - higher-order functions
  - polymorphism
- Logic, the mathematical basis for software engineering:

logic	calculus	
=		
software engineering	mechanical/civil engineering	

- inductively defined sets and relations
- inductive proofs
- proof objects
- Coq, an industrial-strength proof assistant
  - functional core language
  - core tactics
  - automation
- Foundations of programming languages
  - notations and definitional techniques for precisely specifying

- \* abstract syntax
- \* operational semantics
  - $\cdot$ big-step style
  - $\cdot$  small-step style
- \* type systems
- program equivalence
- Hoare logic
- fundamental metatheory of type systems
  - \* progress and preservation
- theory of subtyping

## 1.3 Looking Forward

Some good places to go for more...

- Several optional chapters of Software Foundations
- Cutting-edge conferences on programming languages and formal verification:
  - POPL
  - PLDI
  - OOPSLA
  - ICFP
  - CAV
  - (and many others)
- More on functional programming
  - Learn You a Haskell for Great Good, by Miran Lipovaca (ebook)
  - and many other texts on Haskell, OCaml, Scheme, Scala, ...
- More on Hoare logic and program verification
  - The Formal Semantics of Programming Languages: An Introduction, by Glynn Winskel. MIT Press, 1993.
  - Many practical verification tools, e.g. Microsoft's Boogie system, Java Extended Static Checking, etc.

- More on the foundations of programming languages:
  - Types and Programming Languages, by Benjamin C. Pierce. MIT Press, 2002.
  - Practical Foundations for Programming Languages, by Robert Harper. Forthcoming from MIT Press. Manuscript available from his web page.
  - Foundations for Programming Languages, by John C. Mitchell. MIT Press, 1996.

#### • More on Coq:

### 2.1 PE: Partial Evaluation

Equiv.v introduced constant folding as an example of a program transformation and proved that it preserves the meaning of the program. Constant folding operates on manifest constants such as ANum expressions. For example, it simplifies the command Y ::= APlus (ANum 3) (ANum 1) to the command Y ::= ANum 4. However, it does not propagate known constants along data flow. For example, it does not simplify the sequence X ::= ANum 3;; Y ::= APlus (AId X) (ANum 1) to X ::= ANum 3;; Y ::= ANum 4 because it forgets that X is 3 by the time it gets to Y.

We naturally want to enhance constant folding so that it propagates known constants and uses them to simplify programs. Doing so constitutes a rudimentary form of partial evaluation. As we will see, partial evaluation is so called because it is like running a program, except only part of the program can be evaluated because only part of the input to the program is known. For example, we can only simplify the program X ::= ANum 3;; Y ::= AMinus (APlus (AId X) (ANum 1)) (AId Y) to <math>X ::= ANum 3;; Y ::= AMinus (ANum 4) (AId Y) without knowing the initial value of Y.

Require Export Imp.
Require Import FunctionalExtensionality.

## 2.2 Generalizing Constant Folding

The starting point of partial evaluation is to represent our partial knowledge about the state. For example, between the two assignments above, the partial evaluator may know only that X is 3 and nothing about any other variable.

#### 2.2.1 Partial States

Conceptually speaking, we can think of such partial states as the type  $id \to option$  nat (as opposed to the type  $id \to nat$  of concrete, full states). However, in addition to looking up and updating the values of individual variables in a partial state, we may also want to compare two partial states to see if and where they differ, to handle conditional control flow. It is not possible to compare two arbitrary functions in this way, so we represent partial states in a more concrete format: as a list of  $id \times nat$  pairs.

```
Definition pe_state := list (id \times nat).
```

The idea is that a variable **id** appears in the list if and only if we know its current **nat** value. The **pe\_lookup** function thus interprets this concrete representation. (If the same variable **id** appears multiple times in the list, the first occurrence wins, but we will define our partial evaluator to never construct such a **pe\_state**.)

For example, empty\_pe\_state represents complete ignorance about every variable – the function that maps every id to None.

```
Definition empty_pe_state : pe_state := [].
```

```
Tactic Notation "compare" ident(i) ident(j) ident(c) := let H := fresh "Heq" i j in destruct (eq_id_dec i j); [ Case\_aux c "equal"; subst j | Case\_aux c "not equal" ]. Theorem pe_domain: \forall pe\_st V n, pe_lookup pe\_st V = Some n \rightarrow In V (map (\bigcircfst \_ \_) pe\_st). Proof. intros pe\_st V n H. induction pe\_st as [| [V' n'] pe\_st]. Case "[]". inversion H. Case "::". simpl in H. simpl. compare V V' SCase; auto. Qed.
```

#### Aside on In.

We will make heavy use of the In predicate from the standard library. In is equivalent to the appears\_in predicate introduced in Logic.v, but defined using a Fixpoint rather than an Inductive.

```
Print In.
```

In comes with various useful lemmas.

```
Check in_or_app.
Check filter_In.
Check in_dec.
```

Note that we can compute with in\_dec, just as with eq\_id\_dec.

### 2.2.2 Arithmetic Expressions

Partial evaluation of **aexp** is straightforward – it is basically the same as constant folding, fold\_constants\_aexp, except that sometimes the partial state tells us the current value of a variable and we can replace it by a constant expression.

```
Fixpoint pe_aexp (pe_st : pe_state) (a : aexp) : aexp :=
  match a with
    ANum n \Rightarrow ANum n
  | Ald i \Rightarrow \text{match pe_lookup } pe_st i \text{ with}
                 | Some n \Rightarrow ANum n
                 | None \Rightarrow Ald i
                 end
  | APlus a1 a2 \Rightarrow
       match (pe_aexp pe_st \ a1, pe_aexp pe_st \ a2) with
        (ANum n1, ANum n2) \Rightarrow ANum (n1 + n2)
       (a1', a2') \Rightarrow APlus a1' a2'
        end
  | AMinus a1 \ a2 \Rightarrow
       match (pe_aexp pe_st \ a1, pe_aexp pe_st \ a2) with
        (ANum n1, ANum n2) \Rightarrow ANum (n1 - n2)
       (a1', a2') \Rightarrow AMinus a1' a2'
        end
  | AMult a1 \ a2 \Rightarrow
       match (pe_aexp pe_st a1, pe_aexp pe_st a2) with
        (ANum n1, ANum n2) \Rightarrow ANum (n1 \times n2)
       (a1', a2') \Rightarrow \mathsf{AMult} \ a1' \ a2'
        end
  end.
```

This partial evaluator folds constants but does not apply the associativity of addition.

```
Example test_pe_aexp1:
    pe_aexp [(X,3)] (APlus (APlus (Ald X) (ANum 1)) (Ald Y))
    = APlus (ANum 4) (Ald Y).
Proof. reflexivity. Qed.
Example text_pe_aexp2:
    pe_aexp [(Y,3)] (APlus (APlus (Ald X) (ANum 1)) (Ald Y))
    = APlus (APlus (Ald X) (ANum 1)) (ANum 3).
Proof. reflexivity. Qed.
```

Now, in what sense is  $pe_aexp$  correct? It is reasonable to define the correctness of  $pe_aexp$  as follows: whenever a full state st:state is consistent with a partial state  $pe_st$ : $pe_st$  (in other words, every variable to which  $pe_st$  assigns a value is assigned the same value by st), evaluating  $pe_aexp$   $pe_st$   $pe_st$ 

```
Definition pe_consistent (st: state) (pe_-st: pe_-state) := \forall \ V \ n, Some n = \text{pe}\_lookup \ pe_-st \ V \rightarrow st \ V = n.

Theorem pe_aexp_correct_weak: \forall \ st \ pe_-st, pe_consistent st \ pe_-st \rightarrow \forall \ a, aeval st \ a = \text{aeval} \ st \ (\text{pe}\_aexp \ pe_-st \ a).

Proof. unfold pe_consistent. intros st \ pe_-st \ H \ a.

aexp\_cases (induction a) Case; simpl;
 try reflexivity;
 try (destruct (pe_aexp pe_-st \ a1);
 destruct (pe_aexp pe_-st \ a2);
 rewrite IHa1; rewrite IHa2; reflexivity).

Case \ "AId".

remember (pe_lookup pe_-st \ i) as l. destruct l.

SCase \ "Some". rewrite H \ with \ (n:=n) by apply Heql. reflexivity.

Qed.
```

However, we will soon want our partial evaluator to remove assignments. For example, it will simplify X ::= ANum 3;; Y ::= AMinus (AId X) (AId Y);; X ::= ANum 4 to just Y ::= AMinus (ANum 3) (AId Y);; X ::= ANum 4 by delaying the assignment to X until the end. To accomplish this simplification, we need the result of partial evaluating  $pe_aexp(X,3)$  (AMinus (AId X) (AId Y)) to be equal to AMinus (ANum 3) (Ald Y) and not the original expression AMinus (AId X) (AId Y). After all, it would be incorrect, not just inefficient, to transform X ::= ANum 3;; Y ::= AMinus (AId X) (AId Y);; X ::= ANum 4 to Y ::= AMinus (AId X) (AId Y);; X ::= ANum 4 even though the output expressions AMinus (ANum 3) (Ald Y) and AMinus (AId X) (AId Y) both satisfy the correctness criterion that we just proved. Indeed, if we were to just define  $pe_aexp_be_s$  a = a then the theorem  $pe_aexp_be_s$  would already trivially hold.

Instead, we want to prove that the  $pe_aexp$  is correct in a stronger sense: evaluating the expression produced by partial evaluation (aeval st ( $pe_aexp$   $pe_st$  a)) must not depend

on those parts of the full state st that are already specified in the partial state  $pe\_st$ . To be more precise, let us define a function  $pe\_override$ , which updates st with the contents of  $pe\_st$ . In other words,  $pe\_override$  carries out the assignments listed in  $pe\_st$  on top of st.

```
Fixpoint pe_override (st:state) (pe_st:pe_state): state := match pe_st with | [] \Rightarrow st | (V,n)::pe_st \Rightarrow \text{update } (\text{pe_override } st \ pe_st) \ V \ n end. 

Example test_pe_override: pe_override (\text{update empty_state Y 1}) \ [(X,3);(Z,2)] = \text{update } (\text{update } (\text{update empty_state Y 1}) \ Z \ 2) \ X \ 3. Proof. reflexivity. Qed.
```

Although pe\_override operates on a concrete **list** representing a pe\_state, its behavior is defined entirely by the pe\_lookup interpretation of the pe\_state.

```
Theorem pe_override_correct: \forall st\ pe\_st\ V0, pe_override st\ pe\_st\ V0 = match pe_lookup pe\_st\ V0 with | Some n\Rightarrow n | None \Rightarrow st\ V0 end. Proof. intros. induction pe\_st as [|\ [V\ n]\ pe\_st]. reflexivity. simpl in *. unfold update. compare\ V0\ V\ Case; auto. rewrite eq_id; auto. rewrite neq\_id; auto. Qed.
```

We can relate pe\_consistent to pe\_override in two ways. First, overriding a state with a partial state always gives a state that is consistent with the partial state. Second, if a state is already consistent with a partial state, then overriding the state with the partial state gives the same state.

```
Theorem pe_override_consistent: \forall \ st \ pe\_st, pe_consistent (pe_override st \ pe\_st) \ pe\_st.

Proof. intros st \ pe\_st \ V \ n \ H. rewrite pe_override_correct. destruct (pe_lookup pe\_st \ V); inversion H. reflexivity. Qed. Theorem pe_consistent_override: \forall \ st \ pe\_st, pe_consistent st \ pe\_st \ \to \ V, \ st \ V = \text{pe_override} \ st \ pe\_st \ V.

Proof. intros st \ pe\_st \ H \ V. rewrite pe_override_correct. remember (pe_lookup pe\_st \ V) as l. destruct l; auto. Qed.
```

Now we can state and prove that pe\_aexp is correct in the stronger sense that will help us define the rest of the partial evaluator.

Intuitively, running a program using partial evaluation is a two-stage process. In the first, static stage, we partially evaluate the given program with respect to some partial state to get a residual program. In the second, dynamic stage, we evaluate the residual program with

respect to the rest of the state. This dynamic state provides values for those variables that are unknown in the static (partial) state. Thus, the residual program should be equivalent to *prepending* the assignments listed in the partial state to the original program.

```
Theorem pe_aexp_correct: \forall \ (pe\_st: pe\_state) \ (a: aexp) \ (st: state), aeval (pe_override st \ pe\_st) \ a = aeval \ st \ (pe\_aexp \ pe\_st \ a).

Proof.

intros pe\_st \ a \ st.

aexp\_cases (induction a) Case; simpl;

try reflexivity;

try (destruct (pe_aexp pe\_st \ a1);

destruct (pe_aexp pe\_st \ a2);

rewrite \ IHa1; rewrite IHa2; reflexivity).

rewrite pe_override_correct. destruct (pe_lookup pe\_st \ i); reflexivity.

Qed.
```

### 2.2.3 Boolean Expressions

The partial evaluation of boolean expressions is similar. In fact, it is entirely analogous to the constant folding of boolean expressions, because our language has no boolean variables.

```
Fixpoint pe_bexp (pe_st : pe_state) (b : bexp) : bexp :=
  match b with
    BTrue \Rightarrow BTrue
    BFalse \Rightarrow BFalse
   BEq a1 \ a2 \Rightarrow
       match (pe_aexp pe_st a1, pe_aexp pe_st a2) with
        (ANum n1, ANum n2) \Rightarrow if beq_nat n1 n2 then BTrue else BFalse
       |(a1', a2') \Rightarrow \mathsf{BEq}\ a1'\ a2'
       end
  BLe a1 a2 \Rightarrow
       match (pe_aexp pe_st a1, pe_aexp pe_st a2) with
        | (ANum n1, ANum n2) \Rightarrow if ble_nat n1 n2 then BTrue else BFalse
       (a1', a2') \Rightarrow BLe a1' a2'
        end
  | BNot b1 \Rightarrow
       match (pe_bexp pe_st b1) with
         \mathsf{BTrue} \Rightarrow \mathsf{BFalse}
         BFalse \Rightarrow BTrue
        |b1' \Rightarrow BNot b1'
        end
  \mid BAnd b1 b2 \Rightarrow
       match (pe_bexp pe_st \ b1, pe_bexp pe_st \ b2) with
       | (BTrue, BTrue) \Rightarrow BTrue
```

```
| (BTrue, BFalse) \Rightarrow BFalse
         (BFalse, BTrue) \Rightarrow BFalse
        | (BFalse, BFalse) \Rightarrow BFalse
        (b1', b2') \Rightarrow \mathsf{BAnd}\ b1'\ b2'
        end
  end.
Example test_pe_bexp1:
  pe_bexp[(X,3)] (BNot (BLe (Ald X) (ANum 3)))
  = BFalse.
Proof. reflexivity. Qed.
Example test_pe_bexp2: \forall b,
  b = \mathsf{BNot} \; (\mathsf{BLe} \; (\mathsf{AId} \; \mathsf{X}) \; (\mathsf{APlus} \; (\mathsf{AId} \; \mathsf{X}) \; (\mathsf{ANum} \; 1))) \to
  pe_bexp [] b = b.
Proof. intros b H. rewrite \rightarrow H. reflexivity. Qed.
    The correctness of pe_bexp is analogous to the correctness of pe_aexp above.
Theorem pe_bexp_correct: \forall (pe_st:pe_state) (b:bexp) (st:state),
  beval (pe_override st \ pe_st) \ b = beval \ st \ (pe_bexp \ pe_st \ b).
Proof.
  intros pe_{-}st \ b \ st.
  bexp\_cases (induction b) Case; simpl;
     try reflexivity;
     try (remember (pe_aexp pe_st a) as a';
            remember (pe_aexp pe\_st a\theta) as a\theta';
            assert (Ha: aeval (pe_override st \ pe_st) a = aeval \ st \ a');
            assert (Ha\theta: aeval (pe_override st \ pe_st) a\theta = aeval st \ a\theta');
              try (subst; apply pe_aexp_correct);
            destruct a'; destruct a\theta'; rewrite Ha; rewrite Ha\theta;
            simpl; try destruct (beq_nat n \ n\theta); try destruct (ble_nat n \ n\theta);
            reflexivity);
     try (destruct (pe_bexp pe_st b); rewrite IHb; reflexivity);
     try (destruct (pe_bexp pe_st b1);
            destruct (pe_bexp pe_st \ b2);
            rewrite IHb1; rewrite IHb2; reflexivity).
Qed.
```

## 2.3 Partial Evaluation of Commands, Without Loops

What about the partial evaluation of commands? The analogy between partial evaluation and full evaluation continues: Just as full evaluation of a command turns an initial state into a final state, partial evaluation of a command turns an initial partial state into a final partial state. The difference is that, because the state is partial, some parts of the command

may not be executable at the static stage. Therefore, just as pe\_aexp returns a residual aexp and pe\_bexp returns a residual bexp above, partially evaluating a command yields a residual command.

Another way in which our partial evaluator is similar to a full evaluator is that it does not terminate on all commands. It is not hard to build a partial evaluator that terminates on all commands; what is hard is building a partial evaluator that terminates on all commands yet automatically performs desired optimizations such as unrolling loops. Often a partial evaluator can be coaxed into terminating more often and performing more optimizations by writing the source program differently so that the separation between static and dynamic information becomes more apparent. Such coaxing is the art of binding-time improvement. The binding time of a variable tells when its value is known – either "static", or "dynamic."

Anyway, for now we will just live with the fact that our partial evaluator is not a total function from the source command and the initial partial state to the residual command and the final partial state. To model this non-termination, just as with the full evaluation of commands, we use an inductively defined relation. We write c1 / st || c1' / st' to mean that partially evaluating the source command c1 in the initial partial state st yields the residual command c1' and the final partial state st'. For example, we want something like (X ::= ANum 3 ;; Y ::= AMult (AId Z) (APlus (AId X) (AId X))) /  $\Box$  || (Y ::= AMult (AId Z) (ANum 6)) / (X,3) to hold. The assignment to X appears in the final partial state, not the residual command.

### 2.3.1 Assignment

Let's start by considering how to partially evaluate an assignment. The two assignments in the source program above needs to be treated differently. The first assignment X ::= ANum 3, is *static*: its right-hand-side is a constant (more generally, simplifies to a constant), so we should update our partial state at X to 3 and produce no residual code. (Actually, we produce a residual *SKIP*.) The second assignment Y ::= AMult (Ald Z) (APlus (Ald X) (Ald X)) is *dynamic*: its right-hand-side does not simplify to a constant, so we should leave it in the residual code and remove Y, if present, from our partial state. To implement these two cases, we define the functions pe\_add and pe\_remove. Like pe\_override above, these functions operate on a concrete list representing a pe\_state, but the theorems pe\_add\_correct and pe\_remove\_correct specify their behavior by the pe\_lookup interpretation of the pe\_state.

```
Proof. intros pe_-st V V0. induction pe_-st as [[V' n'] pe_-st].
  Case "[]". destruct (eq_id_dec V V0); reflexivity.
  Case "::". simpl. compare V V' SCase.
    SCase "equal". rewrite IHpe_st.
      destruct (eq_id_dec V V0). reflexivity. rewrite neg_id; auto.
    SCase "not equal". simpl. compare V0 V' SSCase.
       SSCase "equal". rewrite neg_id; auto.
       SSCase "not equal". rewrite IHpe_st. reflexivity.
Qed.
Definition pe_add (pe_st:pe_state) (V:id) (n:nat) : pe_state :=
  (V, n) :: pe_remove pe_st V.
Theorem pe_add_correct: \forall pe_st \ V \ n \ V\theta,
  pe_lookup (pe_add pe_st \ V \ n) \ V\theta
  = if eq_id_dec V V\theta then Some n else pe_lookup pe_-st V\theta.
Proof. intros pe\_st\ V\ n\ VO. unfold pe\_add. simpl.
  compare\ V\ V0\ Case.
  Case "equal". rewrite eq_id; auto.
  Case "not equal". rewrite pe_remove_correct. repeat rewrite neq_id; auto.
Qed.
```

We will use the two theorems below to show that our partial evaluator correctly deals with dynamic assignments and static assignments, respectively.

```
Theorem pe_override_update_remove: \forall \ st \ pe\_st \ V \ n, update (pe_override st \ pe\_st) \ V \ n = pe_override (update st \ V \ n) (pe_remove pe\_st \ V).

Proof. intros st \ pe\_st \ V \ n. apply functional_extensionality. intros V0. unfold update. rewrite !pe_override_correct. rewrite pe_remove_correct. destruct (eq_id_dec V \ V0); reflexivity. Qed.

Theorem pe_override_update_add: \forall \ st \ pe\_st \ V \ n, update (pe_override st \ pe\_st \ V \ n).

Proof. intros st \ pe\_st \ V \ n. apply functional_extensionality. intros V0. unfold update. rewrite !pe_override_correct. rewrite pe_add_correct. destruct (eq_id_dec V \ V0); reflexivity. Qed.
```

#### 2.3.2 Conditional

Trickier than assignments to partially evaluate is the conditional,  $IFB\ b1\ THEN\ c1\ ELSE\ c2\ FI$ . If b1 simplifies to BTrue or BFalse then it's easy: we know which branch will be taken, so just take that branch. If b1 does not simplify to a constant, then we need to take both branches, and the final partial state may differ between the two branches!

The following program illustrates the difficulty: X ::= ANum 3;; IFB BLe (AId Y) (ANum

4) THEN Y ::= ANum 4;; IFB BEq (AId X) (AId Y) THEN Y ::= ANum 999 ELSE SKIP FI ELSE SKIP FI Suppose the initial partial state is empty. We don't know statically how Y compares to 4, so we must partially evaluate both branches of the (outer) conditional. On the THEN branch, we know that Y is set to 4 and can even use that knowledge to simplify the code somewhat. On the ELSE branch, we still don't know the exact value of Y at the end. What should the final partial state and residual program be?

One way to handle such a dynamic conditional is to take the intersection of the final partial states of the two branches. In this example, we take the intersection of (Y,4),(X,3) and (X,3), so the overall final partial state is (X,3). To compensate for forgetting that Y is 4, we need to add an assignment Y := ANum 4 to the end of the THEN branch. So, the residual program will be something like SKIP;; IFB BLe (AId Y) (ANum 4) THEN SKIP;; SKIP;; Y := ANum 4 ELSE SKIP FI

Programming this case in Coq calls for several auxiliary functions: we need to compute the intersection of two pe\_states and turn their difference into sequences of assignments.

First, we show how to compute whether two pe\_states to disagree at a given variable. In the theorem pe\_disagree\_domain, we prove that two pe\_states can only disagree at variables that appear in at least one of them.

```
Definition pe_disagree_at (pe_st1 pe_st2 : pe_state) (V:id) : bool :=
  match pe_lookup pe_-st1 V, pe_lookup pe_-st2 V with
  | Some x, Some y \Rightarrow \text{negb} (beq_nat x y)
   None, None \Rightarrow false
  | \_, \_ \Rightarrow \mathsf{true}
  end.
Theorem pe_disagree_domain: \forall (pe\_st1 \ pe\_st2 : pe\_state) \ (V:id),
  true = pe_disagree_at pe_st1 pe_st2 V \rightarrow
  In V (map (@fst _ _) pe_st1 ++ map (@fst _ _) pe_st2).
Proof. unfold pe_disagree_at. intros pe_st1 pe_st2 V H.
  apply in_or_app.
  remember (pe_lookup pe\_st1 V) as lookup1.
  destruct lookup1 as [n1]. left. apply pe_domain with n1. auto.
  remember (pe_lookup pe_st2 V) as lookup2.
  destruct lookup2 as |n2|. right. apply pe_domain with n2. auto.
  inversion H. Qed.
```

We define the pe\_compare function to list the variables where two given pe\_states disagree. This list is exact, according to the theorem pe\_compare\_correct: a variable appears on the list if and only if the two given pe\_states disagree at that variable. Furthermore, we use the pe\_unique function to eliminate duplicates from the list.

```
Fixpoint pe_unique (l: \mathsf{list} \; \mathsf{id}) : \mathsf{list} \; \mathsf{id} :=  match l with | \; [] \Rightarrow []  | \; x :: l \Rightarrow x :: \; \mathsf{filter} \; (\mathsf{fun} \; y \Rightarrow \mathsf{if} \; \mathsf{eq\_id\_dec} \; x \; y \; \mathsf{then} \; \mathsf{false} \; \mathsf{else} \; \mathsf{true}) \; (\mathsf{pe\_unique} \; l)
```

```
end.
Theorem pe_unique_correct: \forall l x,
  \ln x \ l \leftrightarrow \ln x \ (\text{pe\_unique } l).
Proof. intros l x. induction l as [|h|t]. reflexivity.
  simpl in *. split.
  Case "->".
    intros. inversion H; clear H.
       left. assumption.
      destruct (eq_id_dec h x).
          left. assumption.
          right. apply filter_In. split.
            apply IHt. assumption.
            rewrite neq_id; auto.
  Case "<-".
    intros. inversion H; clear H.
        left. assumption.
        apply filter_In in H0. inversion H0. right. apply IHt. assumption.
Qed.
Definition pe_compare (pe\_st1 \ pe\_st2 : pe\_state) : list id :=
  pe_unique (filter (pe_disagree_at pe_st1 pe_st2)
    (map (@fst \_ \_) pe\_st1 ++ map (@fst \_ \_) pe\_st2)).
Theorem pe_compare_correct: \forall pe\_st1 \ pe\_st2 \ V,
  pe_lookup pe_st1 V = pe_lookup pe_st2 V \leftrightarrow

    unfold pe_disagree_at in Hagree.
    destruct (pe_lookup pe_-st1 V) as [n1];
    destruct (pe_lookup pe_st2 V) as [n2];
```

```
try reflexivity; try solve by inversion. rewrite negb_false_iff in Hagree. apply beq_nat_true in Hagree. subst. reflexivity. Qed.
```

The intersection of two partial states is the result of removing from one of them all the variables where the two disagree. We define the function pe\_removes, in terms of pe\_remove above, to perform such a removal of a whole list of variables at once.

The theorem pe\_compare\_removes testifies that the pe\_lookup interpretation of the result of this intersection operation is the same no matter which of the two partial states we remove the variables from. Because pe\_override only depends on the pe\_lookup interpretation of partial states, pe\_override also does not care which of the two partial states we remove the variables from; that theorem pe\_compare\_override is used in the correctness proof shortly.

```
Fixpoint pe_removes (pe_st:pe_state) (ids:list id):pe_state:=
  match ids with
  | \square \Rightarrow pe\_st
  V::ids \Rightarrow pe\_remove (pe\_removes pe\_st ids) V
Theorem pe_removes_correct: \forall pe_st ids V,
  pe_lookup (pe_removes pe_st ids) V =
  if in_dec eq_id_dec V ids then None else pe_lookup pe_-st V.
Proof. intros pe\_st ids V. induction ids as [V' ids]. reflexivity.
  simpl. rewrite pe_remove_correct. rewrite IHids.
  compare V' V Case.
    reflexivity.
    destruct (in_dec eq_id_dec V ids);
      reflexivity.
Qed.
Theorem pe_compare_removes: \forall pe\_st1 \ pe\_st2 \ V,
  pe_lookup (pe_removes pe_st1 (pe_compare pe_st1 pe_st2)) V =
  pe_lookup (pe_removes pe_st2 (pe_compare pe_st1 pe_st2)) V.
Proof. intros pe\_st1 pe\_st2 V. rewrite !pe_removes_correct.
  destruct (in_dec eq_id_dec V (pe_compare pe_st1 pe_st2)).
    reflexivity.
    apply pe_compare_correct. auto. Qed.
Theorem pe_compare_override: \forall pe\_st1 \ pe\_st2 \ st,
  pe_override st (pe_removes pe_st1 (pe_compare pe_st1 pe_st2)) =
  pe_override st (pe_removes pe_-st2 (pe_compare pe_-st1 pe_-st2)).
Proof. intros. apply functional_extensionality. intros V.
  rewrite !pe_override_correct. rewrite pe_compare_removes. reflexivity.
Qed.
```

Finally, we define an assign function to turn the difference between two partial states into a sequence of assignment commands. More precisely, assign  $pe_-st$  ids generates an

assignment command for each variable listed in ids.

```
Fixpoint assign (pe\_st: pe\_state) (ids: list id): com:= match ids with
| [] \Rightarrow SKIP
| V::ids \Rightarrow match pe\_lookup pe\_st V with
| Some n \Rightarrow (assign pe\_st ids;; V::= ANum n)
| None \Rightarrow assign pe\_st ids
end
end.
```

The command generated by assign always terminates, because it is just a sequence of assignments. The (total) function assigned below computes the effect of the command on the (dynamic state). The theorem assign\_removes then confirms that the generated assignments perfectly compensate for removing the variables from the partial state.

```
Definition assigned (pe\_st:pe\_state) (ids: list id) (st:state) : state :=
  fun V \Rightarrow if in_{dec} eq_{id_{dec}} V ids then
                   match pe_lookup pe_-st \ V with
                     Some n \Rightarrow n
                    | None \Rightarrow st V
                   end
             else st\ V.
Theorem assign_removes: \forall pe\_st \ ids \ st,
  pe_override st pe_st =
  pe_override (assigned pe_st ids st) (pe_removes pe_st ids).
Proof. intros pe_st ids st. apply functional_extensionality. intros V.
  rewrite !pe_override_correct. rewrite pe_removes_correct. unfold assigned.
  destruct (in_dec eq_id_dec V ids); destruct (pe_lookup pe_st V); reflexivity.
Qed.
Lemma ceval_extensionality: \forall c \ st \ st1 \ st2,
  c / st \mid \mid st1 \rightarrow (\forall V, st1 \ V = st2 \ V) \rightarrow c / st \mid \mid st2.
Proof. intros c st st1 st2 H Heq.
  apply functional_extensionality in Heq. rewrite \leftarrow Heq. apply H. Qed.
Theorem eval_assign: \forall pe\_st ids st,
  assign pe\_st ids / st \mid \mid assigned pe\_st ids st.
Proof. intros pe\_st ids st. induction ids as [V ids]; simpl.
  Case "[]". eapply ceval_extensionality. apply E_Skip. reflexivity.

```

#### 2.3.3 The Partial Evaluation Relation

At long last, we can define a partial evaluator for commands without loops, as an inductive relation! The inequality conditions in PE\_AssDynamic and PE\_If are just to keep the partial evaluator deterministic; they are not required for correctness.

```
Reserved Notation "c1 '/' st '||' c1' '/' st'"
   (at level 40, st at level 39, c1' at level 39).
Inductive pe\_com : com \rightarrow pe\_state \rightarrow com \rightarrow pe\_state \rightarrow Prop :=
   \mid \mathsf{PE\_Skip} : \forall \ pe\_st,
         SKIP / pe_st | SKIP / pe_st
   \mid \mathsf{PE\_AssStatic} : \forall pe\_st \ a1 \ n1 \ l,
         pe_aexp pe_st \ a1 = ANum \ n1 \rightarrow
         (l := a1) / pe\_st \mid \mid SKIP / pe\_add pe\_st l n1
   \mid \mathsf{PE\_AssDynamic} : \forall pe\_st \ a1 \ a1' \ l
         pe_aexp pe_st \ a1 = a1' \rightarrow
         (\forall n, a1' \neq \mathsf{ANum}\ n) \rightarrow
         (l ::= a1) / pe_st \mid \mid (l ::= a1') / pe_remove pe_st l
   | PE\_Seq : \forall pe\_st pe\_st' pe\_st'' c1 c2 c1' c2',
         c1 / pe\_st \mid \mid c1' / pe\_st' \rightarrow
         c2 / pe_st' \mid \mid c2' / pe_st'' \rightarrow
         (c1;; c2) / pe_st || (c1';; c2') / pe_st''
   \mid \mathsf{PE\_IfTrue} : \forall \ pe\_st \ pe\_st' \ b1 \ c1 \ c2 \ c1',
         pe_bexp pe_st b1 = BTrue \rightarrow
         c1 / pe_st \mid \mid c1' / pe_st' \rightarrow
         (IFB b1 THEN c1 ELSE c2 FI) / pe\_st || c1' / pe\_st'
   \mid \mathsf{PE\_IfFalse} : \forall \ pe\_st \ pe\_st' \ b1 \ c1 \ c2 \ c2',
         pe_bexp pe_st b1 = BFalse \rightarrow
         c2 / pe_st \mid \mid c2' / pe_st' \rightarrow
         (IFB b1 THEN c1 ELSE c2 FI) / pe_-st || c2' / pe_-st'
   |\mathsf{PE\_If}: \forall pe\_st pe\_st1 pe\_st2 b1 c1 c2 c1' c2',
         pe_bexp pe_st b1 \neq BTrue \rightarrow
         pe_bexp pe_st \ b1 \neq \mathsf{BFalse} \rightarrow
         c1 / pe_st \mid | c1' / pe_st1 \rightarrow
         c2 / pe\_st \mid \mid c2' / pe\_st2 \rightarrow
         (IFB b1 THEN c1 ELSE c2 FI) / pe\_st
```

```
THEN c1';; assign pe_st1 (pe_compare pe_st1 pe_st2)
ELSE c2';; assign pe_st2 (pe_compare pe_st1 pe_st2) FI)
/ pe_removes pe_st1 (pe_compare pe_st1 pe_st2)
where "c1'/' st'||' c1''/' st'" := (pe_com c1 st c1' st').

Tactic Notation "pe_com_cases" tactic(first) ident(c) := first;
[ Case_aux c "PE_Skip"
| Case_aux c "PE_AssStatic" | Case_aux c "PE_AssDynamic"
| Case_aux c "PE_Seq"
| Case_aux c "PE_IfTrue" | Case_aux c "PE_IfFalse" | Case_aux c "PE_If"].

Hint Constructors pe_com.
Hint Constructors ceval.
```

### 2.3.4 Examples

Below are some examples of using the partial evaluator. To make the **pe\_com** relation actually usable for automatic partial evaluation, we would need to define more automation tactics in Coq. That is not hard to do, but it is not needed here.

```
Example pe_example1:
  (X ::= ANum 3 ;; Y ::= AMult (Ald Z) (APlus (Ald X) (Ald X)))
  / [] || (SKIP;; Y ::= AMult (Ald Z) (ANum 6)) / [(X,3)].
Proof. eapply PE_Seq. eapply PE_AssStatic. reflexivity.
  eapply PE_AssDynamic. reflexivity. intros n H. inversion H. Qed.
Example pe_example2:
  (X ::= ANum 3 ;; IFB BLe (Ald X) (ANum 4) THEN X ::= ANum 4 ELSE SKIP FI)
  /[] || (SKIP;; SKIP) / [(X,4)].
Proof. eapply PE_Seq. eapply PE_AssStatic. reflexivity.
  eapply PE_IfTrue. reflexivity.
  eapply PE_AssStatic. reflexivity. Qed.
Example pe_example3:
  (X ::= ANum 3;;
   IFB BLe (Ald Y) (ANum 4) THEN
     Y ::= ANum 4;;
     IFB BEq (Ald X) (Ald Y) THEN Y ::= ANum 999 ELSE SKIP FI
  ELSE SKIP FI) / []
  || (SKIP;;
       IFB BLe (Ald Y) (ANum 4) THEN
         (SKIP;; SKIP);; (SKIP;; Y ::= ANum 4)
       ELSE SKIP;; SKIP FI)
```

```
/[(X,3)].
Proof. erewrite f_{equal2} with (f := fun \ c \ st \Rightarrow // | | | c / st).
  eapply PE_Seq. eapply PE_AssStatic. reflexivity.
  eapply PE_If; intuition eauto; try solve by inversion.
  econstructor. eapply PE_AssStatic. reflexivity.
  eapply PE_IfFalse. reflexivity. econstructor.
  reflexivity. reflexivity. Qed.
2.3.5
          Correctness of Partial Evaluation
Finally let's prove that this partial evaluator is correct!

\text{Qed.}
```

## 2.4 Partial Evaluation of Loops

It may seem straightforward at first glance to extend the partial evaluation relation  $pe\_com$  above to loops. Indeed, many loops are easy to deal with. Considered this repeated-squaring loop, for example: WHILE BLe (ANum 1) (AId X) DO Y ::= AMult (AId Y) (AId Y);; X ::= AMinus (AId X) (ANum 1) END If we know neither X nor Y statically, then the entire loop is dynamic and the residual command should be the same. If we know X but not Y, then the loop can be unrolled all the way and the residual command should be Y ::= AMult (AId Y) (AId Y);; Y ::= AMult (AId Y) (AId Y) if X is initially 3 (and finally 0). In general, a loop is easy to partially evaluate if the final partial state of the loop body is equal to the initial state, or if its guard condition is static.

But there are other loops for which it is hard to express the residual program we want in Imp. For example, take this program for checking if Y is even or odd: X ::= ANum 0;; WHILE BLe (ANum 1) (AId Y) DO Y ::= AMinus (AId Y) (ANum 1);; X ::= AMinus (ANum 1) (AId X) END The value of X alternates between 0 and 1 during the loop. Ideally, we would like to unroll this loop, not all the way but two-fold, into something like WHILE BLe (ANum 1) (AId Y) DO Y ::= AMinus (AId Y) (ANum 1);; IF BLe (ANum 1) (AId Y) THEN Y ::= AMinus (AId Y) (ANum 1) ELSE X ::= ANum 1;; EXIT FI END;; X ::= ANum 0 Unfortunately, there is no EXIT command in Imp. Without extending the range of control structures available in our language, the best we can do is to repeat loop-guard tests or add flag variables. Neither option is terribly attractive.

Still, as a digression, below is an attempt at performing partial evaluation on Imp commands. We add one more command argument c" to the **pe\_com** relation, which keeps track of a loop to roll up.

Module LOOP.

#### 2.4.2 Correctness

Because this partial evaluator can unroll a loop n-fold where n is a (finite) integer greater than one, in order to show it correct we need to perform induction not structurally on dynamic evaluation but on the number of times dynamic evaluation enters a loop body.

```
Reserved Notation "c1 '/' st '||' st' '#' n" (at level 40, st at level 39, st' at level 39). Inductive ceval_count : com \rightarrow state \rightarrow state \rightarrow nat \rightarrow Prop := | E'Skip : \forall st,

# 2.5 Partial Evaluation of Flowchart Programs

Instead of partially evaluating WHILE loops directly, the standard approach to partially evaluating imperative programs is to convert them into flowcharts. In other words, it turns out that adding labels and jumps to our language makes it much easier to partially evaluate. The result of partially evaluating a flowchart is a residual flowchart. If we are lucky, the jumps in the residual flowchart can be converted back to WHILE loops, but that is not possible in general; we do not pursue it here.

#### 2.5.1 Basic blocks

A flowchart is made of basic blocks, which we represent with the inductive type **block**. A basic block is a sequence of assignments (the constructor Assign), concluding with a conditional jump (the constructor If) or an unconditional jump (the constructor Goto). The destinations of the jumps are specified by labels, which can be of any type. Therefore, we parameterize the **block** type by the type of labels.

```
Inductive block (Label:Type): Type:=

| Goto: Label 	o block \ Label
| If: bexp 	o Label 	o Label 	o block \ Label
| Assign: id 	o aexp 	o block \ Label 	o block \ Label.

Tactic Notation "block_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c "Goto" | Case\_aux \ c "If" | Case\_aux \ c "Assign" ].

Arguments \ Goto \ \{Label\} \ \_
Arguments \ If \ \{Label\} \ \_
Arguments \ Assign \ \{Label\} \ \_
Arguments \ Assign \ \{Label\} \ \_
```

We use the "even or odd" program, expressed above in Imp, as our running example. Converting this program into a flowchart turns out to require 4 labels, so we define the following type.

```
Inductive parity_label : Type :=
  | entry : parity_label
  | loop : parity_label
  | body : parity_label
  | done : parity_label.
```

The following **block** is the basic block found at the **body** label of the example program.

```
\begin{array}{l} {\tt Definition\ parity\_body:\ block\ parity\_label:=}\\ {\tt Assign\ Y\ (AMinus\ (Ald\ Y)\ (ANum\ 1))}\\ {\tt (Assign\ X\ (AMinus\ (ANum\ 1)\ (Ald\ X))}\\ {\tt (Goto\ loop)).} \end{array}
```

To evaluate a basic block, given an initial state, is to compute the final state and the label to jump to next. Because basic blocks do not *contain* loops or other control structures, evaluation of basic blocks is a total function – we don't need to worry about non-termination.

```
Fixpoint keval {L:Type} (st:state) (k: block L): state \times L:= match k with \mid Goto l\Rightarrow (st, l) \mid If b l1 l2\Rightarrow (st, if beval <math>st b then l1 else l2) \mid Assign i a k\Rightarrow keval (update st i (aeval st a)) k end
```

Example keval\_example:

```
keval empty_state parity_body
= (update (update empty_state Y 0) X 1, loop).
Proof. reflexivity. Qed.
```

## 2.5.2 Flowchart programs

A flowchart program is simply a lookup function that maps labels to basic blocks. Actually, some labels are *halting states* and do not map to any basic block. So, more precisely, a flowchart program whose labels are of type L is a function from L to **option** (block L).

```
Definition program (L:Type): Type := L \to \operatorname{option} (block L). Definition parity: program \operatorname{parity\_label} := \operatorname{fun} l \Rightarrow \operatorname{match} l with |\operatorname{entry} \Rightarrow \operatorname{Some} (\operatorname{Assign} \mathsf{X} (\operatorname{ANum} 0) (\operatorname{Goto} \operatorname{loop})) | \operatorname{loop} \Rightarrow \operatorname{Some} (\operatorname{If} (\operatorname{BLe} (\operatorname{ANum} 1) (\operatorname{Ald} \mathsf{Y})) \operatorname{body} \operatorname{done}) | \operatorname{body} \Rightarrow \operatorname{Some} \operatorname{parity\_body} | \operatorname{done} \Rightarrow \operatorname{None} \operatorname{end}.
```

Unlike a basic block, a program may not terminate, so we model the evaluation of programs by an inductive relation **peval** rather than a recursive function.

```
Inductive peval \{L:Type\}\ (p:program\ L)
  : state \rightarrow L \rightarrow state \rightarrow L \rightarrow Prop :=
  \mid \mathsf{E}_{-}\mathsf{None}: \ \forall \ \mathit{st} \ \mathit{l},
     p l = None \rightarrow
     peval p st l st l
  | E_Some: \forall st \ l \ k \ st' \ l' \ st'' \ l'',
     p \ l = Some \ k \rightarrow
     keval st k = (st', l') \rightarrow
     peval p \ st' \ l' \ st'' \ l'' \rightarrow
     peval p st l st'' l''.
Example parity_eval: peval parity empty_state entry empty_state done.
Proof. erewrite f_{equal} with (f := fun \ st \Rightarrow peval \_ \_ \_ st \_).
  eapply E_Some. reflexivity. reflexivity.
  eapply E_Some. reflexivity. reflexivity.
  apply E_None. reflexivity.
  apply functional_extensionality. intros i. rewrite update_same; auto.
Qed.
Tactic Notation "peval_cases" tactic(first) ident(c) :=
  first:
  [ Case\_aux \ c "E_None" | Case\_aux \ c "E_Some" ].
```

## 2.5.3 Partial evaluation of basic blocks and flowchart programs

Partial evaluation changes the label type in a systematic way: if the label type used to be L, it becomes  $pe\_state \times L$ . So the same label in the original program may be unfolded, or blown up, into multiple labels by being paired with different partial states. For example, the label loop in the parity program will become two labels: ([(X,0)], loop) and ([(X,1)], loop). This change of label type is reflected in the types of  $pe\_block$  and  $pe\_program$  defined presently.

```
Fixpoint pe_block \{L:Type\}\ (pe_st:pe_state)\ (k:block\ L)
  : block (pe_state \times L) :=
  \mathtt{match}\ k with
   Goto l \Rightarrow \text{Goto } (pe\_st, l)
  | If b l1 l2 \Rightarrow
    match pe_bexp pe_-st b with
     \mid BTrue \Rightarrow Goto (pe_-st, l1)
      BFalse \Rightarrow Goto (pe_-st, l2)
     |b' \Rightarrow |fb'| (pe_st, l1) (pe_st, l2)
     end
  | Assign i \ a \ k \Rightarrow
    match pe_aexp pe_-st a with
     ANum n \Rightarrow pe\_block (pe\_add pe\_st i n) k
     a' \Rightarrow Assign \ a' \ (pe\_block \ (pe\_remove \ pe\_st \ i) \ k)
     end
  end.
Example pe_block_example:
  pe_block [(X,0)] parity_body
  = Assign Y (AMinus (Ald Y) (ANum 1)) (Goto ([(X,1)], loop)).
Proof. reflexivity. Qed.

# Chapter 3

# Library UseAuto

# 3.1 UseAuto: Theory and Practice of Automation in Coq Proofs

In a machine-checked proof, every single detail has to be justified. This can result in huge proof scripts. Fortunately, Coq comes with a proof-search mechanism and with several decision procedures that enable the system to automatically synthesize simple pieces of proof. Automation is very powerful when set up appropriately. The purpose of this chapter is to explain the basics of working of automation.

The chapter is organized in two parts. The first part focuses on a general mechanism called "proof search." In short, proof search consists in naively trying to apply lemmas and assumptions in all possible ways. The second part describes "decision procedures", which are tactics that are very good at solving proof obligations that fall in some particular fragment of the logic of Coq.

Many of the examples used in this chapter consist of small lemmas that have been made up to illustrate particular aspects of automation. These examples are completely independent from the rest of the Software Foundations course. This chapter also contains some bigger examples which are used to explain how to use automation in realistic proofs. These examples are taken from other chapters of the course (mostly from STLC), and the proofs that we present make use of the tactics from the library LibTactics.v, which is presented in the chapter UseTactics.

Require Import LibTactics.

# 3.2 Basic Features of Proof Search

The idea of proof search is to replace a sequence of tactics applying lemmas and assumptions with a call to a single tactic, for example auto. This form of proof automation saves a lot of effort. It typically leads to much shorter proof scripts, and to scripts that are typically more robust to change. If one makes a little change to a definition, a proof that exploits automation

probably won't need to be modified at all. Of course, using too much automation is a bad idea. When a proof script no longer records the main arguments of a proof, it becomes difficult to fix it when it gets broken after a change in a definition. Overall, a reasonable use of automation is generally a big win, as it saves a lot of time both in building proof scripts and in subsequently maintaining those proof scripts.

## 3.2.1 Strength of Proof Search

We are going to study four proof-search tactics: auto, eauto, iauto and jauto. The tactics auto and eauto are builtin in Coq. The tactic iauto is a shorthand for the builtin tactic try solve [intuition eauto]. The tactic jauto is defined in the library LibTactics, and simply performs some preprocessing of the goal before calling eauto. The goal of this chapter is to explain the general principles of proof search and to give rule of thumbs for guessing which of the four tactics mentioned above is best suited for solving a given goal.

Proof search is a compromise between efficiency and expressiveness, that is, a tradeoff between how complex goals the tactic can solve and how much time the tactic requires for terminating. The tactic auto builds proofs only by using the basic tactics reflexivity, assumption, and apply. The tactic eauto can also exploit eapply. The tactic jauto extends eauto by being able to open conjunctions and existentials that occur in the context. The tactic iauto is able to deal with conjunctions, disjunctions, and negation in a quite clever way; however it is not able to open existentials from the context. Also, iauto usually becomes very slow when the goal involves several disjunctions.

Note that proof search tactics never perform any rewriting step (tactics rewrite, subst), nor any case analysis on an arbitrary data structure or predicate (tactics destruct and inversion), nor any proof by induction (tactic induction). So, proof search is really intended to automate the final steps from the various branches of a proof. It is not able to discover the overall structure of a proof.

#### 3.2.2 Basics

The tactic auto is able to solve a goal that can be proved using a sequence of intros, apply, assumption, and reflexivity. Two examples follow. The first one shows the ability for auto to call reflexivity at any time. In fact, calling reflexivity is always the first thing that auto tries to do.

```
Lemma solving_by_reflexivity : 2 + 3 = 5.
Proof. auto. Qed.
```

The second example illustrates a proof where a sequence of two calls to apply are needed. The goal is to prove that if Q n implies P n for any n and if Q n holds for any n, then P 2 holds.

```
Lemma solving_by_apply : \forall (P \ Q : \mathbf{nat} \rightarrow \mathsf{Prop}), (\forall n, Q \ n \rightarrow P \ n) \rightarrow
```

```
 \begin{array}{ccc} (\forall \ n, \ Q \ n) \rightarrow \\ P \ 2. \end{array}
```

Proof. auto. Qed.

We can ask auto to tell us what proof it came up with, by invoking *info\_auto* in place of auto.

```
\begin{array}{c} \mathsf{Lemma\ solving\_by\_apply'}: \ \forall \ (P\ Q: \mathbf{nat} {\rightarrow} \mathsf{Prop}), \\ (\forall \ n, \ Q\ n \rightarrow P\ n) \rightarrow \\ (\forall \ n, \ Q\ n) \rightarrow \\ P\ 2. \end{array}
```

Proof.  $info\_auto$ . Qed.

The tactic auto can invoke apply but not eapply. So, auto cannot exploit lemmas whose instantiation cannot be directly deduced from the proof goal. To exploit such lemmas, one needs to invoke the tactic eauto, which is able to call eapply.

In the following example, the first hypothesis asserts that P n is true when Q m is true for some m, and the goal is to prove that Q 1 implies P 2. This implication follows direction from the hypothesis by instantiating m as the value 1. The following proof script shows that eauto successfully solves the goal, whereas auto is not able to do so.

Remark: Again, we can use info\_eauto to see what proof eauto comes up with.

# 3.2.3 Conjunctions

So far, we've seen that eauto is stronger than auto in the sense that it can deal with eapply. In the same way, we are going to see how *jauto* and *iauto* are stronger than auto and eauto in the sense that they provide better support for conjunctions.

The tactics auto and eauto can prove a goal of the form  $F \wedge F'$ , where F and F' are two propositions, as soon as both F and F' can be proved in the current context. An example follows.

```
Lemma solving_conj_goal : \forall (P : nat\rightarrowProp) (F : Prop), (\forall n, P n) \rightarrow F \rightarrow F \wedge P 2. Proof. auto. Qed.
```

However, when an assumption is a conjunction, auto and eauto are not able to exploit this conjunction. It can be quite surprising at first that eauto can prove very complex goals but that it fails to prove that  $F \wedge F'$  implies F. The tactics *iauto* and *jauto* are able to decompose conjunctions from the context. Here is an example.

```
Lemma solving_conj_hyp : \forall (F F' : Prop), F \land F' \rightarrow F.
```

Proof. auto. eauto. jauto. Qed.

The tactic *jauto* is implemented by first calling a pre-processing tactic called *jauto\_set*, and then calling eauto. So, to understand how *jauto* works, one can directly call the tactic *jauto\_set*.

```
Lemma solving_conj_hyp' : \forall (F F' : Prop), F \land F' \rightarrow F.

Proof. intros. jauto\_set. eauto. Qed.
```

Next is a more involved goal that can be solved by *iauto* and *jauto*.

```
Lemma solving_conj_more : \forall (P Q R : \operatorname{nat} \to \operatorname{Prop}) (F : \operatorname{Prop}), (F \wedge (\forall n \ m, (Q \ m \wedge R \ n) \to P \ n)) \to (F \to R \ 2) \to Q \ 1 \to P \ 2 \wedge F.

Proof. jauto. Qed.
```

The strategy of *iauto* and *jauto* is to run a global analysis of the top-level conjunctions, and then call eauto. For this reason, those tactics are not good at dealing with conjunctions that occur as the conclusion of some universally quantified hypothesis. The following example illustrates a general weakness of Coq proof search mechanisms.

```
 \begin{split} \operatorname{Lemma solving\_conj\_hyp\_forall} : & \forall \ (P \ Q : \operatorname{nat} \rightarrow \operatorname{Prop}), \\ & (\forall \ n, \ P \ n \ \land \ Q \ n) \rightarrow P \ 2. \\ & \operatorname{Proof.} \\ & \operatorname{auto. \ eauto. \ } iauto. \ jauto. \\ & \operatorname{intros. \ destruct} \ (H \ 2). \ \operatorname{auto.} \\ & \operatorname{Qed.} \end{split}
```

This situation is slightly disappointing, since automation is able to prove the following goal, which is very similar. The only difference is that the universal quantification has been distributed over the conjunction.

```
Lemma solved_by_jauto : \forall (P Q : \mathsf{nat} \rightarrow \mathsf{Prop}) (F : \mathsf{Prop}), (\forall n, P n) \land (\forall n, Q n) \rightarrow P 2. Proof. jauto. Qed.
```

## 3.2.4 Disjunctions

The tactics auto and eauto can handle disjunctions that occur in the goal.

However, only *iauto* is able to automate reasoning on the disjunctions that appear in the context. For example, *iauto* can prove that  $F \vee F'$  entails  $F' \vee F$ .

More generally, *iauto* can deal with complex combinations of conjunctions, disjunctions, and negations. Here is an example.

```
Lemma solving_tauto : \forall (F1 F2 F3 : Prop), 
 (\neg F1 \land F3) \lor (F2 \land \neg F3)) \rightarrow
 (F2 \rightarrow F1) \rightarrow
 (F2 \rightarrow F3) \rightarrow
 \neg F2.
```

Proof. iauto. Qed.

However, the ability of *iauto* to automatically perform a case analysis on disjunctions comes with a downside: *iauto* may be very slow. If the context involves several hypotheses with disjunctions, *iauto* typically generates an exponential number of subgoals on which eauto is called. One major advantage of *jauto* compared with *iauto* is that it never spends time performing this kind of case analyses.

#### 3.2.5 Existentials

The tactics eauto, iauto, and jauto can prove goals whose conclusion is an existential. For example, if the goal is  $\exists x$ , f x, the tactic eauto introduces an existential variable, say ?25, in place of x. The remaining goal is f ?25, and eauto tries to solve this goal, allowing itself to instantiate ?25 with any appropriate value. For example, if an assumption f 2 is available, then the variable ?25 gets instantiated with 2 and the goal is solved, as shown below.

```
Lemma solving_exists_goal : \forall (f : \mathbf{nat} \rightarrow \mathsf{Prop}), f \ 2 \rightarrow \exists \ x, f \ x.

Proof.

auto. Qed.
```

A major strength of *jauto* over the other proof search tactics is that it is able to exploit the existentially-quantified hypotheses, i.e., those of the form  $\exists x, P$ .

```
Lemma solving_exists_hyp : \forall (f \ g : \mathbf{nat} \rightarrow \mathsf{Prop}), (\forall \ x, f \ x \rightarrow g \ x) \rightarrow (\exists \ a, f \ a) \rightarrow (\exists \ a, g \ a).
Proof.
auto. eauto. iauto. jauto. Qed.
```

## 3.2.6 Negation

The tactics auto and eauto suffer from some limitations with respect to the manipulation of negations, mostly related to the fact that negation, written  $\neg P$ , is defined as  $P \rightarrow False$  but

that the unfolding of this definition is not performed automatically. Consider the following example.

```
Lemma negation_study_1: \forall (P: \mathbf{nat} \rightarrow \mathsf{Prop}), P \ 0 \rightarrow (\forall x, \neg P \ x) \rightarrow \mathsf{False}.
Proof.
intros P \ H0 \ HX.
eauto. unfold not in *. eauto.
Qed.
```

For this reason, the tactics *iauto* and *jauto* systematically invoke unfold not in \* as part of their pre-processing. So, they are able to solve the previous goal right away.

```
Lemma negation_study_2 : \forall (P : nat\rightarrowProp), P 0 \rightarrow (\forall x, \neg P x) \rightarrow False. Proof. jauto. Qed.
```

We will come back later on to the behavior of proof search with respect to the unfolding of definitions.

## 3.2.7 Equalities

Coq's proof-search feature is not good at exploiting equalities. It can do very basic operations, like exploiting reflexivity and symmetry, but that's about it. Here is a simple example that auto can solve, by first calling symmetry and then applying the hypothesis.

```
Lemma equality_by_auto : \forall (f g : \mathsf{nat} \rightarrow \mathsf{Prop}), (\forall x, f x = g x) \rightarrow g 2 = f 2. Proof. auto. Qed.
```

To automate more advanced reasoning on equalities, one should rather try to use the tactic congruence, which is presented at the end of this chapter in the "Decision Procedures" section.

## 3.3 How Proof Search Works

# 3.3.1 Search Depth

The tactic auto works as follows. It first tries to call reflexivity and assumption. If one of these calls solves the goal, the job is done. Otherwise auto tries to apply the most recently introduced assumption that can be applied to the goal without producing and error. This application produces subgoals. There are two possible cases. If the sugboals produced can be solved by a recursive call to auto, then the job is done. Otherwise, if this application produces at least one subgoal that auto cannot solve, then auto starts over by trying to apply the second most recently introduced assumption. It continues in a similar fashion until it finds a proof or until no assumption remains to be tried.

It is very important to have a clear idea of the backtracking process involved in the execution of the auto tactic; otherwise its behavior can be quite puzzling. For example, auto is not able to solve the following triviality.

```
Lemma search_depth_0:
```

```
True \( \text{True} \) \( \tex
```

The reason auto fails to solve the goal is because there are too many conjunctions. If there had been only five of them, auto would have successfully solved the proof, but six is too many. The tactic auto limits the number of lemmas and hypotheses that can be applied in a proof, so as to ensure that the proof search eventually terminates. By default, the maximal number of steps is five. One can specify a different bound, writing for example auto 6 to search for a proof involving at most six steps. For example, auto 6 would solve the previous lemma. (Similarly, one can invoke eauto 6 or intuition eauto 6.) The argument n of auto n is called the "search depth." The tactic auto is simply defined as a shorthand for auto 5.

The behavior of auto n can be summarized as follows. It first tries to solve the goal using reflexivity and assumption. If this fails, it tries to apply a hypothesis (or a lemma that has been registered in the hint database), and this application produces a number of sugoals. The tactic auto (n-1) is then called on each of those subgoals. If all the subgoals are solved, the job is completed, otherwise auto n tries to apply a different hypothesis.

During the process, auto n calls auto (n-1), which in turn might call auto (n-2), and so on. The tactic auto 0 only tries reflexivity and assumption, and does not try to apply any lemma. Overall, this means that when the maximal number of steps allowed has been exceeded, the auto tactic stops searching and backtracks to try and investigate other paths.

The following lemma admits a unique proof that involves exactly three steps. So, auto n proves this goal iff n is greater than three.

```
\begin{array}{c} \operatorname{Lemma\ search\_depth\_1}: \ \forall \ (P: \operatorname{nat} \rightarrow \operatorname{Prop}), \\ P\ 0 \rightarrow \\ (P\ 0 \rightarrow P\ 1) \rightarrow \\ (P\ 1 \rightarrow P\ 2) \rightarrow \\ (P\ 2). \\ \\ \operatorname{Proof.} \\ \operatorname{auto\ } 0. \quad \operatorname{auto\ } 1. \quad \operatorname{auto\ } 2. \quad \operatorname{auto\ } 3. \ \operatorname{Qed.} \end{array}
```

We can generalize the example by introducing an assumption asserting that P k is derivable from P (k-1) for all k, and keep the assumption P 0. The tactic auto, which is the same as auto 5, is able to derive P k for all values of k less than 5. For example, it can prove P 4.

```
 \begin{array}{c} \mathsf{Lemma\ search\_depth\_3}: \ \forall \ (P: \mathbf{nat} {\rightarrow} \mathsf{Prop}), \\ (P\ 0) \rightarrow \\ (\forall \ k, \ P\ (k\text{-}1) \rightarrow P\ k) \rightarrow \\ (P\ 4). \end{array}
```

Proof. auto. Qed.

However, to prove P 5, one needs to call at least auto 6.

```
 \begin{array}{c} \mathsf{Lemma\ search\_depth\_4}: \ \forall \ (P: \mathbf{nat} {\rightarrow} \mathsf{Prop}), \\ (P\ 0) \rightarrow \\ (\forall \ k, \ P\ (k\text{-}1) \rightarrow P\ k) \rightarrow \\ (P\ 5). \end{array}
```

Proof. auto. auto 6. Qed.

Because auto looks for proofs at a limited depth, there are cases where auto can prove a goal F and can prove a goal F' but cannot prove  $F \wedge F'$ . In the following example, auto can prove P 4 but it is not able to prove P 4  $\wedge$  P 4, because the splitting of the conjunction consumes one proof step. To prove the conjunction, one needs to increase the search depth, using at least auto 6.

```
 \begin{array}{c} \mathsf{Lemma\ search\_depth\_5}: \ \forall \ (P: \mathbf{nat} {\rightarrow} \mathsf{Prop}), \\ (P\ 0) \rightarrow \\ (\forall \ k, \ P\ (k\text{-}1) \rightarrow P\ k) \rightarrow \\ (P\ 4 \land P\ 4). \\ \mathsf{Proof.\ auto.\ auto\ 6.\ Qed.} \end{array}
```

## 3.3.2 Backtracking

In the previous section, we have considered proofs where at each step there was a unique assumption that auto could apply. In general, auto can have several choices at every step. The strategy of auto consists of trying all of the possibilities (using a depth-first search exploration).

To illustrate how automation works, we are going to extend the previous example with an additional assumption asserting that P k is also derivable from P (k+1). Adding this hypothesis offers a new possibility that auto could consider at every step.

There exists a special command that one can use for tracing all the steps that proofsearch considers. To view such a trace, one should write debug eauto. (For some reason, the command debug auto does not exist, so we have to use the command debug eauto instead.)

```
 \begin{array}{c} \mathsf{Lemma\ working\_of\_auto\_1}: \ \forall \ (P: \mathbf{nat} {\rightarrow} \mathsf{Prop}), \\ (P\ 0) \rightarrow \\ (\forall \ k, \ P\ (k{+}1) \rightarrow P\ k) \rightarrow \\ (\forall \ k, \ P\ (k{-}1) \rightarrow P\ k) \rightarrow \\ (P\ 2). \end{array}
```

Proof. intros  $P\ H1\ H2\ H3$ . eauto. Qed.

The output message produced by debug eauto is as follows.

```
depth=5
depth=4 apply H3
depth=3 apply H3
depth=3 exact H1
```

The depth indicates the value of n with which eauto n is called. The tactics shown in the message indicate that the first thing that eauto has tried to do is to apply H3. The effect of applying H3 is to replace the goal P 2 with the goal P 1. Then, again, H3 has been applied, changing the goal P 1 into P 0. At that point, the goal was exactly the hypothesis H1.

It seems that eauto was quite lucky there, as it never even tried to use the hypothesis H2 at any time. The reason is that auto always tries to use the most recently introduced hypothesis first, and H3 is a more recent hypothesis than H2 in the goal. So, let's permute the hypotheses H2 and H3 and see what happens.

```
Lemma working_of_auto_2 : \forall (P : \mathbf{nat} \rightarrow \mathsf{Prop}), (P 0) \rightarrow (\forall k, P (k-1) \rightarrow P k) \rightarrow (\forall k, P (k+1) \rightarrow P k) \rightarrow (P 2).

Proof. intros P H1 H3 H2. eauto. Qed.
```

This time, the output message suggests that the proof search investigates many possibilities. Replacing debug eauto with  $info\_eauto$ , we observe that the proof that eauto comes up with is actually not the simplest one. apply H2; apply H3; apply H3; apply H3; exact H1 This proof goes through the proof obligation P 3, even though it is not any useful. The following tree drawing describes all the goals that automation has been through.

|5||4||3||2||1||0| -- below, tabulation indicates the depth

```
[P 2]
-> [P 3]
   -> [P 4]
      -> [P 5]
          -> [P 6]
             -> [P 7]
             -> [P 5]
          -> [P 4]
             -> [P 5]
             -> [P 3]
       --> [P 3]
          -> [P 4]
             -> [P 5]
             -> [P 3]
          -> [P 2]
             -> [P 3]
             -> [P 1]
   -> [P 2]
      -> [P 3]
          -> [P 4]
             -> [P 5]
```

```
-> [P 3]
-> [P 2]
-> [P 3]
-> [P 1]
-> [P 1]
-> [P 2]
-> [P 3]
-> [P 1]
-> [P 0]
-> !! Done !!
```

The first few lines read as follows. To prove P 2, eauto 5 has first tried to apply H2, producing the subgoal P 3. To solve it, eauto 4 has tried again to apply H2, producing the goal P 4. Similarly, the search goes through P 5, P 6 and P 7. When reaching P 7, the tactic eauto 0 is called but as it is not allowed to try and apply any lemma, it fails. So, we come back to the goal P 6, and try this time to apply hypothesis H3, producing the subgoal P 5. Here again, eauto 0 fails to solve this goal.

The process goes on and on, until backtracking to P 3 and trying to apply H2 three times in a row, going through P 2 and P 1 and P 0. This search tree explains why eauto came up with a proof starting with apply H2.

## 3.3.3 Adding Hints

By default, auto (and eauto) only tries to apply the hypotheses that appear in the proof context. There are two possibilities for telling auto to exploit a lemma that have been proved previously: either adding the lemma as an assumption just before calling auto, or adding the lemma as a hint, so that it can be used by every calls to auto.

The first possibility is useful to have auto exploit a lemma that only serves at this particular point. To add the lemma as hypothesis, one can type generalize mylemma; intros, or simply lets: mylemma (the latter requires LibTactics.v).

The second possibility is useful for lemmas that need to be exploited several times. The syntax for adding a lemma as a hint is Hint Resolve mylemma. For example, the lemma asserting than any number is less than or equal to itself,  $\forall x, x \leq x$ , called  $Le.le\_refl$  in the Coq standard library, can be added as a hint as follows.

#### Hint Resolve Le.le\_refl.

A convenient shorthand for adding all the constructors of an inductive datatype as hints is the command Hint Constructors *mydatatype*.

Warning: some lemmas, such as transitivity results, should not be added as hints as they would very badly affect the performance of proof search. The description of this problem and the presentation of a general work-around for transitivity lemmas appear further on.

## 3.3.4 Integration of Automation in Tactics

The definition of *auto\_star*, which determines the meaning of the star symbol, can be modified whenever needed. Simply write: Ltac auto\_star ::= a\_new\_definition. ]] Observe the use of ::= instead of :=, which indicates that the tactic is being rebound to a new definition. So, the default definition is as follows.

Ltac  $auto\_star ::= try solve [ auto | jauto ].$ 

Nearly all standard Coq tactics and all the tactics from "LibTactics" can be called with a star symbol. For example, one can invoke  $\mathtt{subst} \times$ ,  $\mathtt{destruct} \times H$ ,  $inverts \times H$ ,  $lets \times I$ : H  $\mathsf{x}$ ,  $specializes \times H$   $\mathsf{x}$ , and so on... There are two notable exceptions. The tactic  $\mathtt{auto} \times \mathsf{is}$  just another name for the tactic  $auto\_star$ . And the tactic  $\mathtt{apply} \times H$  calls  $\mathtt{eapply} H$  (or the more powerful applys H if needed), and then calls  $auto\_star$ . Note that there is no  $\mathtt{eapply} \times H$  tactic, use  $\mathtt{apply} \times H$  instead.

In large developments, it can be convenient to use two degrees of automation. Typically, one would use a fast tactic, like auto, and a slower but more powerful tactic, like jauto. To allow for a smooth coexistence of the two form of automation, LibTactics.v also defines a "tilde" version of tactics, like apply¬H, destruct¬H, subst¬, auto¬ and so on. The meaning of the tilde symbol is described by the  $auto\_tilde$  tactic, whose default implementation is auto.

Ltac  $auto\_tilde ::= auto.$ 

In the examples that follow, only *auto\_star* is needed.

# 3.4 Examples of Use of Automation

Let's see how to use proof search in practice on the main theorems of the "Software Foundations" course, proving in particular results such as determinism, preservation and progress.

#### 3.4.1 Determinism

Module DeterministicImp.

Require Import Imp.

Recall the original proof of the determinism lemma for the IMP language, shown below.

Theorem ceval\_deterministic:  $\forall c \ st \ st1 \ st2$ ,

```
c / st \mid \mid st1 \rightarrow
  c / st \mid \mid st2 \rightarrow
  st1 = st2.
Proof.
  intros c st st1 st2 E1 E2.
  generalize dependent st2.
  (ceval\_cases (induction E1) Case); intros st2 E2; inversion E2; subst.
  Case "E_Skip". reflexivity.
  Case "E_Ass". reflexivity.
  Case "E_Seq".
    assert (st' = st'0) as EQ1.
       SCase "Proof of assertion". apply IHE1_1; assumption.
    subst st'\theta.
    apply IHE1_{-}2. assumption.
  Case "E_IfTrue".
    SCase "b1 evaluates to true".
       apply IHE1. assumption.
    SCase "b1 evaluates to false (contradiction)".
      rewrite H in H5. inversion H5.
  Case "E_IfFalse".
    SCase "b1 evaluates to true (contradiction)".
      rewrite H in H5. inversion H5.
    SCase "b1 evaluates to false".
       apply IHE1. assumption.
  Case "E_WhileEnd".
    SCase "b1 evaluates to true".
      reflexivity.
    SCase "b1 evaluates to false (contradiction)".
      rewrite H in H2. inversion H2.
  Case "E_WhileLoop".
    SCase "b1 evaluates to true (contradiction)".
      rewrite H in H4. inversion H4.
    SCase "b1 evaluates to false".
       assert (st' = st'\theta) as EQ1.
         SSCase "Proof of assertion". apply IHE1_1; assumption.
       subst st'\theta.
       apply IHE1_2. assumption.
Qed.
   Exercise: rewrite this proof using auto whenever possible. (The solution uses auto 9
times.)
Theorem ceval_deterministic': \forall c \ st \ st1 \ st2,
  c / st | | st1 \rightarrow
```

```
\begin{array}{c|cccc} c & / & st & | & st2 \rightarrow \\ st1 & = & st2. \end{array} Proof. admit. Qed.
```

In fact, using automation is not just a matter of calling **auto** in place of one or two other tactics. Using automation is about rethinking the organization of sequences of tactics so as to minimize the effort involved in writing and maintaining the proof. This process is eased by the use of the tactics from *LibTactics.v.* So, before trying to optimize the way automation is used, let's first rewrite the proof of determinism:

- use *introv H* instead of intros x H,
- use gen x instead of generalize dependent x,
- use *inverts* H instead of inversion H; subst,
- use tryfalse to handle contradictions, and get rid of the cases where beval st b1 = true and beval st b1 = false both appear in the context,
- stop using *ceval\_cases* to label subcases.

```
Theorem ceval_deterministic'': \forall \ c \ st \ st1 \ st2, c \ / \ st \ | \ | \ st1 \rightarrow c \ / \ st \ | \ | \ st2 \rightarrow st1 = st2.

Proof.

introv \ E1 \ E2. \ gen \ st2.
induction \ E1; \ intros; \ inverts \ E2; \ tryfalse.
auto.
auto.
auto.
assert (st' = st'0). auto. subst. auto.
auto.
auto.
auto.
Qed.
```

To obtain a nice clean proof script, we have to remove the calls assert  $(st' = st'\theta)$ . Such a tactic invokation is not nice because it refers to some variables whose name has been automatically generated. This kind of tactics tend to be very brittle. The tactic assert  $(st' = st'\theta)$  is used to assert the conclusion that we want to derive from the induction hypothesis. So, rather than stating this conclusion explicitly, we are going to ask Coq to instantiate the induction hypothesis, using automation to figure out how to instantiate it.

The tactic forwards, described in LibTactics.v precisely helps with instantiating a fact. So, let's see how it works out on our example.

```
Theorem ceval_deterministic''': \forall c \ st \ st1 \ st2,
  c / st \mid \mid st1 \rightarrow
  c / st || st2 \rightarrow
  st1 = st2.
Proof.
  introv E1 E2. gen st2.
  induction E1; intros; inverts E2; tryfalse.
  auto. auto.
  dup 4.
  assert (st' = st'0). apply IHE1_1. apply H1.
  forwards: IHE1_1. apply H1.
   skip.
  forwards: IHE1_1. eauto.
   skip.
  forwards*: IHE1_1.
   skip.
```

Abort.

To polish the proof script, it remains to factorize the calls to auto, using the star symbol. The proof of determinism can then be rewritten in only four lines, including no more than 10 tactics.

```
Theorem ceval_deterministic''': \forall \ c \ st \ st1 \ st2,
c \ / \ st \ | \ st1 \rightarrow
c \ / \ st \ | \ st2 \rightarrow
st1 = st2.

Proof.

introv \ E1 \ E2. \ gen \ st2.
induction \ E1; \ intros; \ inverts \times \ E2; \ tryfalse.
forwards^*: \ IHE1\_1. \ subst \times.
forwards^*: \ IHE1\_1. \ subst \times.
Qed.
```

#### 3.4.2 Preservation for STLC

End DeterministicImp.

```
Module PreservationProgressStlc. Require Import StlcProp. Import STLC.
```

```
Import STLCProp.
```

Consider the proof of perservation of STLC, shown below. This proof already uses eauto through the triple-dot mechanism.

```
Theorem preservation : \forall t \ t' \ T,
  has_type empty t T \rightarrow
  t ==> t' \rightarrow
  has_type empty t' T.
Proof with eauto.
  remember (@empty ty) as Gamma.
  intros t t T HT. generalize dependent t T.
  (has\_type\_cases (induction HT) Case); intros t' HE; subst Gamma.
  Case "T_Var".
    inversion HE.
  Case "T_Abs".
    inversion HE.
  Case "T_App".
    inversion HE; subst...
    SCase "ST_AppAbs".
      apply substitution_preserves_typing with T11...
      inversion HT1...
  Case "T_True".
    inversion HE.
  Case "T_False".
    inversion HE.
  Case "T_If".
    inversion HE; subst...
Qed.
```

Exercise: rewrite this proof using tactics from LibTactics and calling automation using the star symbol rather than the triple-dot notation. More precisely, make use of the tactics  $inverts \times$  and  $applys \times$  to call auto $\times$  after a call to inverts or to applys. The solution is three lines long.

```
Theorem preservation': \forall \ t \ t' T, has_type empty t \ T \rightarrow t ==> t' \rightarrow has_type empty t' T.

Proof.

admit.

Qed.
```

# 3.4.3 Progress for STLC

Consider the proof of the progress theorem.

```
Theorem progress: \forall t T,
  has_type empty t T \rightarrow
  value t \vee \exists t', t ==> t'.
Proof with eauto.
  intros t T Ht.
  remember (@empty ty) as Gamma.
  (has_type_cases (induction Ht) Case); subst Gamma...
  Case "T_Var".
     inversion H.
  Case "T_App".
    right. destruct IHHt1...
     SCase "t1 is a value".
       destruct IHHt2...
       SSCase "t2 is a value".
         inversion H; subst; try solve by inversion.
         \exists ([x0:=t2]t)...
       SSCase "t2 steps".
        destruct H0 as [t2' Hstp]. \exists (tapp t1 \ t2')...
     SCase "t1 steps".
       destruct H as [t1' Hstp]. \exists (tapp t1' t2)...
  Case "T_If".
    right. destruct IHHt1...
    destruct t1; try solve by inversion...
     inversion H. \exists (tif x0 \ t2 \ t3)...
Qed.
   Exercise: optimize the above proof. Hint: make use of destruct \times and inverts \times. The
solution consists of 10 short lines.
Theorem progress': \forall t T.
  has_type empty t T \rightarrow
  value t \vee \exists t', t ==> t'.
Proof.
   admit.
Qed.
```

End PreservationProgressStlc.

## 3.4.4 BigStep and SmallStep

Module SEMANTICS.
Require Import Smallstep.

Consider the proof relating a small-step reduction judgment to a big-step reduction judgment.

```
Theorem multistep__eval: \forall \ t \ v, normal_form_of t \ v \to \exists \ n, v = C \ n \land t \mid \mid n.

Proof.

intros t \ v \ Hnorm.

unfold normal_form_of in Hnorm.

inversion Hnorm as [Hs \ Hnf]; clear Hnorm.

rewrite nf_same_as_value in Hnf. inversion Hnf. clear Hnf.

\exists \ n. split. reflexivity.

multi_cases (induction Hs) Case; subst.

Case "multi_refl".

apply E_Const.

Case "multi_step".

eapply step_{-}eval. eassumption. apply IHHs. reflexivity.

Qed.
```

Our goal is to optimize the above proof. It is generally easier to isolate inductions into separate lemmas. So, we are going to first prove an intermediate result that consists of the judgment over which the induction is being performed.

Exercise: prove the following result, using tactics *introv*, induction and subst, and apply×. The solution is 3 lines long.

```
Theorem multistep_eval_ind : \forall \ t \ v, t ==>* \ v \to \forall \ n, \ \mathsf{C} \ n = \ v \to t \ | \ | \ n. Proof. admit. Qed.
```

Exercise: using the lemma above, simplify the proof of the result multistep\_eval. You should use the tactics *introv*, *inverts*, split× and apply×. The solution is 2 lines long.

```
Theorem multistep__eval': \forall \ t \ v, normal_form_of t \ v \to \exists \ n, v = C \ n \land t \mid \mid \ n. Proof. admit. Qed.
```

If we try to combine the two proofs into a single one, we will likely fail, because of a limitation of the induction tactic. Indeed, this tactic looses information when applied to a predicate whose arguments are not reduced to variables, such as  $t ==>^* (C n)$ . You will thus need to use the more powerful tactic called dependent induction. This tactic is available only after importing the Program library, as shown below.

```
Require Import Program.
```

Exercise: prove the lemma multistep\_eval without invoking the lemma multistep\_eval\_ind, that is, by inlining the proof by induction involved in multistep\_eval\_ind, using the tactic dependent induction instead of induction. The solution is 5 lines long.

```
Theorem multistep__eval": \forall \ t \ v, normal_form_of t \ v \to \exists \ n, v = C \ n \land t \mid \mid n. Proof. admit. Qed. End SEMANTICS.
```

#### 3.4.5 Preservation for STLCRef

```
Module PreservationProgressReferences.

Require Import References.

Import STLCRef.

Hint Resolve store_weakening extends_refl.
```

The proof of preservation for STLCREF can be found in chapter References. It contains 58 lines (not counting the labelling of cases). The optimized proof script is more than twice shorter. The following material explains how to build the optimized proof script. The resulting optimized proof script for the preservation theorem appears afterwards.

```
Theorem preservation: \forall ST \ t \ t' \ T \ st \ st'
  has_type empty ST\ t\ T \rightarrow
  store_well_typed ST st \rightarrow
  t / st ==> t' / st' \rightarrow
  \exists ST',
     (extends ST' ST \wedge
      has_type empty ST' t' T \land
      store_well_typed ST' st').
Proof.
  remember (@empty ty) as Gamma. introv Ht. gen t'.
  (has_type_cases (induction Ht) Case); introv HST Hstep;
   subst Gamma; inverts\ Hstep; eauto.
  Case "T_App".
  SCase "ST_AppAbs".
  \exists ST. inverts Ht1. splits \times . applys \times substitution_preserves_typing.
  SCase "ST_App1".
  forwards: IHHt1. eauto. eauto. eauto.
  jauto\_set\_hyps; intros.
  jauto\_set\_goal; intros.
  eauto. eauto. eauto.
  SCase "ST_App2".
  forwards*: IHHt2.
```

```
forwards*: IHHt.
  forwards*: IHHt.
  forwards*: IHHt1.
  forwards*: IHHt2.
  forwards*: IHHt1.
  Case "T_Ref".
  SCase "ST_RefValue".
  \exists (snoc ST T1). inverts keep HST. splits.
     apply extends_snoc.
     applys_eq T_Loc 1.
       rewrite length_snoc. omega.
    unfold store_Tlookup. rewrite \leftarrow H. rewrite \times nth_eq_snoc.
     apply× store_well_typed_snoc.
  forwards*: IHHt.
  Case "T_Deref".
  SCase "ST_DerefLoc".
  \exists ST. splits \times.
  lets [\_Hsty]: HST.
  applys_eq \times Hsty 1.
  inverts \times Ht.
  forwards*: IHHt.
  Case "T_Assign".
  SCase "ST_Assign".
  \exists ST. splits \times . applys \times assign_pres_store_typing. inverts \times Ht1.
  forwards*: IHHt1.
  forwards*: IHHt2.
Qed.
```

Let's come back to the proof case that was hard to optimize. The difficulty comes from the statement of  $nth_{eq\_snoc}$ , which takes the form nth (length I) (snoc I x) d = x. This lemma is hard to exploit because its first argument, length I, mentions a list I that has to be exactly the same as the I occurring in snoc I x. In practice, the first argument is often a natural number n that is provably equal to length I yet that is not syntactically equal to length I. There is a simple fix for making  $nth_{eq\_snoc}$  easy to apply: introduce the intermediate variable n explicitly, so that the goal becomes  $nth_{eq\_snoc}$  (snoc I x) d = x, with a premise asserting  $eq_{eq\_snoc}$  length I.

```
Lemma nth_eq_snoc': \forall (A: Type) (l: list A) (x d: A) (n: nat), n = length \ l \rightarrow nth \ n (snoc l \ x) d = x.

Proof. intros. subst. apply nth_eq_snoc. Qed.
```

The proof case for *ref* from the preservation theorem then becomes much easier to prove, because rewrite nth\_eq\_snoc' now succeeds.

```
Lemma preservation_ref : \forall (st:store) (ST : store_ty) T1,
  length ST = length st \rightarrow
  TRef T1 = TRef (store_Tlookup (length st) (snoc ST T1)).
Proof.
  intros. dup.
  unfold store_Tlookup. rewrite × nth_eq_snoc'.
  fequal. symmetry. apply × nth_eq_snoc'.
Qed.
   The optimized proof of preservation is summarized next.
Theorem preservation': \forall ST \ t \ t' \ T \ st \ st',
  has_type empty ST\ t\ T \rightarrow
  store\_well\_typed ST st \rightarrow
  t / st ==> t' / st' \rightarrow
  \exists ST',
     (extends ST' ST \wedge
      has_type empty ST' t' T \land
      store_well_typed ST' st').
Proof.
  remember (@empty ty) as Gamma. introv Ht. gen t'.
  induction Ht; introv HST Hstep; subst Gamma; inverts Hstep; eauto.
  \exists ST. inverts Ht1. splits \times . applys \times substitution_preserves_typing.
  forwards*: IHHt1.
  forwards*: IHHt2.
  forwards*: IHHt.
  forwards*: IHHt.
  forwards*: IHHt1.
  forwards*: IHHt2.
  forwards*: IHHt1.
  \exists (snoc ST T1). inverts keep HST. splits.
     apply extends_snoc.
     applys_eq T_Loc 1.
       rewrite length_snoc. omega.
       unfold store_Tlookup. rewrite × nth_eq_snoc'.
     apply× store_well_typed_snoc.
  forwards*: IHHt.
  \exists ST. splits \times . lets [\_ Hsty]: HST.
    applys\_eq \times Hsty \ 1. \ inverts \times Ht.
  forwards*: IHHt.
  \exists ST. splits \times . applys \times assign_pres_store_typing. inverts \times Ht1.
  forwards*: IHHt1.
  forwards*: IHHt2.
```

## 3.4.6 Progress for STLCRef

The proof of progress for STLCREF can be found in chapter References. It contains 53 lines and the optimized proof script is, here again, half the length.

```
Theorem progress: \forall ST \ t \ T \ st,
  has_type empty ST\ t\ T \rightarrow
  store\_well\_typed ST st \rightarrow
  (value t \vee \exists t', \exists st', t / st \Longrightarrow t' / st').
Proof.
  introv Ht HST. remember (@empty ty) as Gamma.
  induction Ht; subst Gamma; tryfalse; try solve [left*].
  right. destruct \times IHHt1 as [K].
     inverts K; inverts Ht1.
      destruct \times IHHt2.
  right. destruct \times IHHt as [K].
     inverts K; try solve [inverts Ht]. eauto.
  right. destruct \times IHHt as [K].
     inverts \ K; try solve [inverts \ Ht]. eauto.
  right. destruct \times IHHt1 as [K].
     inverts K; try solve [inverts Ht1].
      destruct \times IHHt2 as [M].
       inverts M; try solve [inverts Ht2]. eauto.
  right. destruct \times IHHt1 as [K].
     inverts K; try solve [inverts Ht1]. destruct\times n.
  right. destruct × IHHt.
  right. destruct \times IHHt as [K].
     inverts K; inverts Ht as M.
       inverts HST as N. rewrite \times N in M.
  right. destruct \times IHHt1 as [K].
    destruct \times IHHt2.
      inverts K; inverts Ht1 as M.
      inverts HST as N. rewrite \times N in M.
Qed.
```

End PreservationProgressReferences.

## 3.4.7 Subtyping

Module SUBTYPINGINVERSION. Require Import Sub.

Consider the inversion lemma for typing judgment of abstractions in a type system with subtyping.

Exercise: optimize the proof script, using introv, lets and  $inverts \times$ . In particular, you will find it useful to replace the pattern apply K in H. destruct H as I with lets I: K H. The solution is 4 lines.

```
Lemma abs_arrow': \forall \ x \ S1 \ s2 \ T1 \ T2, 
has_type empty (tabs x \ S1 \ s2) (TArrow T1 \ T2) \rightarrow subtype T1 \ S1 \land has_type (extend empty x \ S1) s2 \ T2. 
Proof. 
admit. 
Qed.
```

The lemma substitution\_preserves\_typing has already been used to illustrate the working of *lets* and *applys* in chapter UseTactics. Optimize further this proof using automation (with the star symbol), and using the tactic *cases\_if*'. The solution is 33 lines, including the *Case* instructions (21 lines without them).

```
Lemma substitution_preserves_typing : \forall Gamma x U v t S, has_type (extend Gamma x U) t S \rightarrow has_type empty v U \rightarrow has_type Gamma ([x:=v]t) S.

Proof.

admit.

Qed.

End SUBTYPINGINVERSION.
```

# 3.5 Advanced Topics in Proof Search

#### 3.5.1 Stating Lemmas in the Right Way

Due to its depth-first strategy, eauto can get exponentially slower as the depth search increases, even when a short proof exists. In general, to make proof search run reasonably fast, one should avoid using a depth search greater than 5 or 6. Moreover, one should try to minimize the number of applicable lemmas, and usually put first the hypotheses whose proof usefully instantiates the existential variables.

In fact, the ability for eauto to solve certain goals actually depends on the order in which the hypotheses are stated. This point is illustrated through the following example, in which P is a predicate on natural numbers. This predicate is such that P n holds for any n as soon as P m holds for at least one m different from zero. The goal is to prove that P 2 implies P 1. When the hypothesis about P is stated in the form  $\forall$  n m, P m  $\rightarrow$  m  $\neq$  0  $\rightarrow$  P n, then eauto works. However, with  $\forall$  n m, m  $\neq$  0  $\rightarrow$  P m  $\rightarrow$  P n, the tactic eauto fails.

```
Lemma order_matters_1 : \forall (P: \mathbf{nat} \rightarrow \mathsf{Prop}), (\forall \ n \ m, \ P \ m \rightarrow m \neq 0 \rightarrow P \ n) \rightarrow P \ 2 \rightarrow P \ 1. Proof.
eauto. Qed.

Lemma order_matters_2 : \forall (P: \mathbf{nat} \rightarrow \mathsf{Prop}), (\forall \ n \ m, \ m \neq 0 \rightarrow P \ m \rightarrow P \ n) \rightarrow P \ 5 \rightarrow P \ 1. Proof.
eauto.
intros P \ H \ K.
eapply H.
eauto.
Abort.
```

It is very important to understand that the hypothesis  $\forall$  n m, P m  $\rightarrow$  m  $\neq$  0  $\rightarrow$  P n is eauto-friendly, whereas  $\forall$  n m, m  $\neq$  0  $\rightarrow$  P m  $\rightarrow$  P n really isn't. Guessing a value of m for which P m holds and then checking that m  $\neq$  0 holds works well because there are few values of m for which P m holds. So, it is likely that eauto comes up with the right one. On the other hand, guessing a value of m for which m  $\neq$  0 and then checking that P m holds does not work well, because there are many values of m that satisfy m  $\neq$  0 but not P m.

# 3.5.2 Unfolding of Definitions During Proof-Search

The use of intermediate definitions is generally encouraged in a formal development as it usually leads to more concise and more readable statements. Yet, definitions can make it a little harder to automate proofs. The problem is that it is not obvious for a proof search mechanism to know when definitions need to be unfolded. Note that a naive strategy that consists in unfolding all definitions before calling proof search does not scale up to large

proofs, so we avoid it. This section introduces a few techniques for avoiding to manually unfold definitions before calling proof search.

To illustrate the treatment of definitions, let P be an abstract predicate on natural numbers, and let myFact be a definition denoting the proposition  $P \times holds$  for any  $\times holds$  for an

```
Axiom P: \mathbf{nat} \to \mathtt{Prop}.
Definition myFact := \forall \ x, \ x \leq 3 \to P \ x.
```

Proving that myFact under the assumption that  $P \times holds$  for any  $\times hould$  be trivial. Yet, auto fails to prove it unless we unfold the definition of myFact explicitly.

```
Lemma demo_hint_unfold_goal_1:
```

```
(\forall x, P x) \rightarrow \mathsf{myFact}.
```

Proof.

auto. unfold myFact. auto. Qed.

To automate the unfolding of definitions that appear as proof obligation, one can use the command Hint Unfold myFact to tell Coq that it should always try to unfold myFact when myFact appears in the goal.

Hint Unfold myFact.

This time, automation is able to see through the definition of myFact.

Lemma demo\_hint\_unfold\_goal\_2:

```
(\forall x, P x) \rightarrow \mathsf{myFact}.
```

Proof. auto. Qed.

However, the Hint Unfold mechanism only works for unfolding definitions that appear in the goal. In general, proof search does not unfold definitions from the context. For example, assume we want to prove that P 3 holds under the assumption that  $True \rightarrow myFact$ .

```
Lemma demo_hint_unfold_context_1:
```

```
(\mathsf{True} \to \mathsf{myFact}) \to P \ 3.
```

Proof.

intros.

auto. unfold myFact in \*. auto. Qed.

There is actually one exception to the previous rule: a constant occurring in an hypothesis is automatically unfolded if the hypothesis can be directly applied to the current goal. For example, auto can prove myFact  $\rightarrow$  P 3, as illustrated below.

```
Lemma\ demo\_hint\_unfold\_context\_2:
```

```
myFact \rightarrow P 3.
```

Proof. auto. Qed.

# 3.5.3 Automation for Proving Absurd Goals

In this section, we'll see that lemmas concluding on a negation are generally not useful as hints, and that lemmas whose conclusion is **False** can be useful hints but having too many of

them makes proof search inefficient. We'll also see a practical work-around to the efficiency issue.

Consider the following lemma, which asserts that a number less than or equal to 3 is not greater than 3.

```
Parameter le\_not\_gt : \forall x, (x \le 3) \rightarrow \neg (x > 3).
```

Equivalently, one could state that a number greater than three is not less than or equal to 3.

```
Parameter gt\_not\_le : \forall x,
(x > 3) \rightarrow \neg (x \le 3).
```

In fact, both statements are equivalent to a third one stating that  $x \le 3$  and x > 3 are contradictory, in the sense that they imply **False**.

```
Parameter le\_gt\_false : \forall x,
(x \le 3) \to (x > 3) \to \textbf{False}.
```

The following investigation aim at figuring out which of the three statments is the most convenient with respect to proof automation. The following material is enclosed inside a **Section**, so as to restrict the scope of the hints that we are adding. In other words, after the end of the section, the hints added within the section will no longer be active.

#### Section DemoAbsurd1.

Let's try to add the first lemma,  $le\_not\_gt$ , as hint, and see whether we can prove that the proposition  $\exists x, x \leq 3 \land x > 3$  is absurd.

```
Hint Resolve le_not_gt.
```

```
Lemma demo_auto_absurd_1: (\exists \ x, \ x \leq 3 \land x > 3) \to \textbf{False}. Proof. intros. jauto\_set. eauto. eapply le\_not\_gt. eauto. eauto. Qed.
```

The lemma  $gt\_not\_le$  is symmetric to  $le\_not\_gt$ , so it will not be any better. The third lemma,  $le\_gt\_false$ , is a more useful hint, because it concludes on False, so proof search will try to apply it when the current goal is False.

```
Hint Resolve le_{-}gt_{-}false.
```

```
Lemma demo_auto_absurd_2 : (\exists \ x \text{, } x \leq 3 \land x > 3) \rightarrow \textbf{False}. Proof. dup. intros. jauto\_set. eauto. jauto. Qed.
```

In summary, a lemma of the form  $H1 \to H2 \to \mathsf{False}$  is a much more effective hint than  $H1 \to \neg H2$ , even though the two statements are equivalent up to the definition of the negation symbol  $\neg$ .

That said, one should be careful with adding lemmas whose conclusion is **False** as hint. The reason is that whenever reaching the goal **False**, the proof search mechanism will potentially try to apply all the hints whose conclusion is **False** before applying the appropriate one.

#### End DemoAbsurd1.

Adding lemmas whose conclusion is **False** as hint can be, locally, a very effective solution. However, this approach does not scale up for global hints. For most practical applications, it is reasonable to give the name of the lemmas to be exploited for deriving a contradiction. The tactic false H, provided by LibTactics serves that purpose: false H replaces the goal with **False** and calls eapply H. Its behavior is described next. Observe that any of the three statements  $le\_not\_gt$ ,  $gt\_not\_le$  or  $le\_gt\_false$  can be used.

```
Lemma demo_false : \forall x, (x \leq 3) \rightarrow (x > 3) \rightarrow 4 = 5. Proof.

intros. dup \ 4.

false. eapply le\_gt\_false.

auto. skip.

false. eapply le\_gt\_false.

eauto. eauto.

false \ le\_gt\_false. eauto. eauto.

false \ le\_not\_gt. eauto. eauto.

Qed.
```

In the above example, false  $le\_gt\_false$ ; eauto proves the goal, but false  $le\_gt\_false$ ; auto does not, because auto does not correctly instantiate the existential variable. Note that false×  $le\_gt\_false$  would not work either, because the star symbol tries to call auto first. So, there are two possibilities for completing the proof: either call false  $le\_gt\_false$ ; eauto, or call false× ( $le\_gt\_false$  3).

# 3.5.4 Automation for Transitivity Lemmas

Some lemmas should never be added as hints, because they would very badly slow down proof search. The typical example is that of transitivity results. This section describes the problem and presents a general workaround.

Consider a subtyping relation, written **subtype** S T, that relates two object S and T of type typ. Assume that this relation has been proved reflexive and transitive. The corresponding lemmas are named  $subtype\_refl$  and  $subtype\_trans$ .

Parameter typ: Type.

```
\begin{array}{l} {\tt Parameter} \ \textit{subtype} : \ \textit{typ} \rightarrow \textit{typ} \rightarrow {\tt Prop}. \\ {\tt Parameter} \ \textit{subtype\_refl} : \ \forall \ T, \\ subtype \ T \ T. \\ {\tt Parameter} \ \textit{subtype\_trans} : \ \forall \ S \ T \ U, \\ subtype \ S \ T \rightarrow \textit{subtype} \ T \ U \rightarrow \textit{subtype} \ S \ U. \end{array}
```

Adding reflexivity as hint is generally a good idea, so let's add reflexivity of subtyping as hint.

#### Hint Resolve subtype\_refl.

Adding transitivity as hint is generally a bad idea. To understand why, let's add it as hint and see what happens. Because we cannot remove hints once we've added them, we are going to open a "Section," so as to restrict the scope of the transitivity hint to that section.

Section HintsTransitivity.

Hint Resolve subtype\_trans.

Now, consider the goal  $\forall$  S T, subtype S T, which clearly has no hope of being solved. Let's call eauto on this goal.

```
\label{eq:lemma_transitivity_bad_hint_1} \begin{subabble} Lemma transitivity\_bad\_hint\_1: $\forall S \ T$, \\ subtype \ S \ T. \\ \end{subabble} Proof.
```

intros. eauto. Abort.

Note that after closing the section, the hint *subtype\_trans* is no longer active.

#### End HintsTransitivity.

In the previous example, the proof search has spent a lot of time trying to apply transitivity and reflexivity in every possible way. Its process can be summarized as follows. The first goal is **subtype** S T. Since reflexivity does not apply, **eauto** invokes transitivity, which produces two subgoals, **subtype** S ?X and **subtype** ?X T. Solving the first subgoal, **subtype** S ?X, is straightforward, it suffices to apply reflexivity. This unifies ?X with S. So, the second sugoal, **subtype** ?X T, becomes **subtype** S T, which is exactly what we started from...

The problem with the transitivity lemma is that it is applicable to any goal concluding on a subtyping relation. Because of this, eauto keeps trying to apply it even though it most often doesn't help to solve the goal. So, one should never add a transitivity lemma as a hint for proof search.

There is a general workaround for having automation to exploit transitivity lemmas without giving up on efficiency. This workaround relies on a powerful mechanism called "external hint." This mechanism allows to manually describe the condition under which a particular lemma should be tried out during proof search.

For the case of transitivity of subtyping, we are going to tell Coq to try and apply the transitivity lemma on a goal of the form **subtype** S U only when the proof context already contains an assumption either of the form **subtype** S U or of the form **subtype** S U. In

other words, we only apply the transitivity lemma when there is some evidence that this application might help. To set up this "external hint," one has to write the following.

```
Hint Extern 1 (subtype ?S?U) \Rightarrow match goal with \mid H: subtype \ S?T \vdash \_ \Rightarrow apply (@subtype\_trans \ S \ T \ U) <math>\mid H: subtype \ ?T \ U \vdash \_ \Rightarrow apply (@subtype\_trans \ S \ T \ U) end.
```

This hint declaration can be understood as follows.

- "Hint Extern" introduces the hint.
- The number "1" corresponds to a priority for proof search. It doesn't matter so much what priority is used in practice.
- The pattern subtype ?S ?U describes the kind of goal on which the pattern should apply. The question marks are used to indicate that the variables ?S and ?U should be bound to some value in the rest of the hint description.
- The construction match goal with ... end tries to recognize patterns in the goal, or in the proof context, or both.
- The first pattern is H: subtype  $S ? T \vdash \bot$ . It indices that the context should contain an hypothesis H of type subtype S ? T, where S has to be the same as in the goal, and where ? T can have any value.
- The symbol  $\vdash$  at the end of H: **subtype**  $S ? T \vdash$  indicates that we do not impose further condition on how the proof obligation has to look like.
- The branch ⇒ apply (@subtype\_trans S T U) that follows indicates that if the goal has the form subtype S U and if there exists an hypothesis of the form subtype S T, then we should try and apply transitivity lemma instantiated on the arguments S, T and U. (Note: the symbol @ in front of subtype\_trans is only actually needed when the "Implicit Arguments" feature is activated.)
- The other branch, which corresponds to an hypothesis of the form H: subtype ? T U is symmetrical.

Note: the same external hint can be reused for any other transitive relation, simply by renaming **subtype** into the name of that relation.

Let us see an example illustrating how the hint works.

```
Lemma transitivity_workaround_1: \forall T1 \ T2 \ T3 \ T4, subtype T1 \ T2 \rightarrow subtype T2 \ T3 \rightarrow subtype T3 \ T4 \rightarrow subtype T1 \ T4. Proof. intros. eauto. Qed.
```

We may also check that the new external hint does not suffer from the complexity blow up.

```
Lemma transitivity_workaround_2 : \forall S \ T, subtype S \ T.

Proof.
intros. eauto. Abort.
```

### 3.6 Decision Procedures

A decision procedure is able to solve proof obligations whose statement admits a particular form. This section describes three useful decision procedures. The tactic omega handles goals involving arithmetic and inequalities, but not general multiplications. The tactic ring handles goals involving arithmetic, including multiplications, but does not support inequalities. The tactic congruence is able to prove equalities and inequalities by exploiting equalities available in the proof context.

#### 3.6.1 Omega

The tactic omega supports natural numbers (type nat) as well as integers (type Z, available by including the module ZArith). It supports addition, substraction, equalities and inequalities. Before using omega, one needs to import the module Omega, as follows.

```
Require Import Omega.
```

Here is an example. Let x and y be two natural numbers (they cannot be negative). Assume y is less than 4, assume x+x+1 is less than y, and assume x is not zero. Then, it must be the case that x is equal to one.

```
Lemma omega_demo_1 : \forall (x \ y : \mathbf{nat}), (y \le 4) \to (x + x + 1 \le y) \to (x \ne 0) \to (x = 1). Proof. intros. omega. Qed.
```

Another example: if z is the mean of x and y, and if the difference between x and y is at most 4, then the difference between x and z is at most 2.

```
Lemma omega_demo_2 : \forall (x \ y \ z : \mathbf{nat}), (x + y = z + z) \rightarrow (x - y \le 4) \rightarrow (x - z \le 2). Proof. intros. omega. Qed.
```

One can proof **False** using omega if the mathematical facts from the context are contradictory. In the following example, the constraints on the values x and y cannot be all satisfied in the same time.

```
Lemma omega_demo_3 : \forall (x \ y : \text{nat}), (x + 5 \le y) \rightarrow (y - x \le 3) \rightarrow \text{False}. Proof. intros. omega. Qed.
```

Note: omega can prove a goal by contradiction only if its conclusion is reduced **False**. The tactic omega always fails when the conclusion is an arbitrary proposition P, even though **False** implies any proposition P (by ex\_falso\_quodlibet).

```
Lemma omega_demo_4 : \forall (x \ y : \mathbf{nat}) (P : \mathsf{Prop}), (x + 5 \le y) \to (y - x \le 3) \to P. Proof. intros. false. omega. Qed.
```

#### 3.6.2 Ring

Compared with omega, the tactic ring adds support for multiplications, however it gives up the ability to reason on inequations. Moreover, it supports only integers (type Z) and not natural numbers (type nat). Here is an example showing how to use ring.

```
Module RINGDEMO.
Require Import ZArith.
Open Scope Z\_scope.

Lemma ring_demo: \forall (x \ y \ z : \mathbf{Z}), \\ x \times (y + z) - z \times 3 \times x \\ = x \times y - 2 \times x \times z.

Proof. intros. ring. Qed.
```

End RINGDEMO.

# 3.6.3 Congruence

The tactic **congruence** is able to exploit equalities from the proof context in order to automatically perform the rewriting operations necessary to establish a goal. It is slightly more powerful than the tactic subst, which can only handle equalities of the form x = e where x is a variable and e an expression.

```
Lemma congruence_demo_1:
```

```
\forall \ (f: \mathbf{nat} \rightarrow \mathbf{nat} \rightarrow \mathbf{nat}) \ (g \ h: \mathbf{nat} \rightarrow \mathbf{nat}) \ (x \ y \ z: \mathbf{nat}), f \ (g \ x) \ (g \ y) = z \rightarrow 2 = g \ x \rightarrow g \ y = h \ z \rightarrow f \ 2 \ (h \ z) = z.
```

Proof. intros. congruence. Qed.

Moreover, congruence is able to exploit universally quantified equalities, for example  $\forall$  a, g a = h a.

```
Lemma congruence_demo_2:
```

```
\forall (f : \mathsf{nat} \rightarrow \mathsf{nat} \rightarrow \mathsf{nat}) (g \ h : \mathsf{nat} \rightarrow \mathsf{nat}) (x \ y \ z : \mathsf{nat}),
```

```
(\forall a, g \ a = h \ a) \rightarrow f \ (g \ x) \ (g \ y) = z \rightarrow g \ x = 2 \rightarrow f \ 2 \ (h \ y) = z.
```

Proof. congruence. Qed.

Next is an example where congruence is very useful.

```
Lemma congruence_demo_4 : \forall (f \ g : \mathbf{nat} \rightarrow \mathbf{nat}), (\forall \ a, f \ a = g \ a) \rightarrow f \ (g \ (g \ 2)) = g \ (f \ (f \ 2)). Proof. congruence. Qed.
```

The tactic **congruence** is able to prove a contradiction if the goal entails an equality that contradicts an inequality available in the proof context.

```
Lemma congruence_demo_3:
```

```
\forall (f \ g \ h : \mathbf{nat} \rightarrow \mathbf{nat}) \ (x : \mathbf{nat}),

(\forall \ a, f \ a = h \ a) \rightarrow

g \ x = f \ x \rightarrow

g \ x \neq h \ x \rightarrow

False.
```

Proof. congruence. Qed.

One of the strengths of congruence is that it is a very fast tactic. So, one should not hesitate to invoke it wherever it might help.

# 3.7 Summary

Let us summarize the main automation tactics available.

- auto automatically applies reflexivity, assumption, and apply.
- eauto moreover tries eapply, and in particular can instantiate existentials in the conclusion.
- *iauto* extends **eauto** with support for negation, conjunctions, and disjunctions. However, its support for disjunction can make it exponentially slow.
- *jauto* extends eauto with support for negation, conjunctions, and existential at the head of hypothesis.
- congruence helps reasoning about equalities and inequalities.
- omega proves arithmetic goals with equalities and inequalities, but it does not support multiplication.
- ring proves arithmetic goals with multiplications, but does not support inequalities.

In order to set up automation appropriately, keep in mind the following rule of thumbs:

- automation is all about balance: not enough automation makes proofs not very robust on change, whereas too much automation makes proofs very hard to fix when they break.
- if a lemma is not goal directed (i.e., some of its variables do not occur in its conclusion), then the premises need to be ordered in such a way that proving the first premises maximizes the chances of correctly instantiating the variables that do not occur in the conclusion.
- a lemma whose conclusion is **False** should only be added as a local hint, i.e., as a hint within the current section.
- a transitivity lemma should never be considered as hint; if automation of transitivity reasoning is really necessary, an Extern Hint needs to be set up.
- a definition usually needs to be accompanied with a Hint Unfold.

Becoming a master in the black art of automation certainly requires some investment, however this investment will pay off very quickly.

# Chapter 4

# Library UseTactics

# 4.1 UseTactics: Tactic Library for Coq: A Gentle Introduction

Coq comes with a set of builtin tactics, such as reflexivity, intros, inversion and so on. While it is possible to conduct proofs using only those tactics, you can significantly increase your productivity by working with a set of more powerful tactics. This chapter describes a number of such very useful tactics, which, for various reasons, are not yet available by default in Coq. These tactics are defined in the *LibTactics.v* file.

#### Require Import LibTactics.

Remark: SSReflect is another package providing powerful tactics. The library "LibTactics" differs from "SSReflect" in two respects:

- "SSReflect" was primarily developed for proving mathematical theorems, whereas "Lib-Tactics" was primarily developed for proving theorems on programming languages. In particular, "LibTactics" provides a number of useful tactics that have no counterpart in the "SSReflect" package.
- "SSReflect" entirely rethinks the presentation of tactics, whereas "LibTactics" mostly stick to the traditional presentation of Coq tactics, simply providing a number of additional tactics. For this reason, "LibTactics" is probably easier to get started with than "SSReflect".

This chapter is a tutorial focusing on the most useful features from the "LibTactics" library. It does not aim at presenting all the features of "LibTactics". The detailed specification of tactics can be found in the source file LibTactics.v. Further documentation as well as demos can be found at http://www.chargueraud.org/softs/tlc/.

In this tutorial, tactics are presented using examples taken from the core chapters of the "Software Foundations" course. To illustrate the various ways in which a given tactic can be used, we use a tactic that duplicates a given goal. More precisely, dup produces two copies of the current goal, and dup n produces n copies of it.

# 4.2 Tactics for introduction and case analysis

This section presents the following tactics:

- *introv*, for naming hypotheses more efficiently,
- *inverts*, for improving the inversion tactic,
- cases, for performing a case analysis without losing information,
- cases\_if, for automating case analysis on the argument of if.

#### 4.2.1 The tactic *introv*

Module IntrovExamples.

Require Import Stlc.

Import Imp STLC.

The tactic *introv* allows to automatically introduce the variables of a theorem and explicitly name the hypotheses involved. In the example shown next, the variables c, st, st1 and st2 involved in the statement of determinism need not be named explicitly, because their name where already given in the statement of the lemma. On the contrary, it is useful to provide names for the two hypotheses, which we name E1 and E2, respectively.

```
Theorem ceval_deterministic: \forall c \ st \ st1 \ st2,
```

```
c / st \mid\mid st1 \rightarrow c / st \mid\mid st2 \rightarrow st1 = st2.
```

introv. Abort.

Proof.

introv E1 E2. Abort.

When there is no hypothesis to be named, one can call *introv* without any argument.

```
Theorem dist_exists_or: \forall (X:Type) (P Q: X \to \text{Prop}), (\exists x, P x \lor Q x) \leftrightarrow (\exists x, P x) \lor (\exists x, Q x). Proof.
```

The tactic *introv* also applies to statements in which  $\forall$  and  $\rightarrow$  are interleaved.

```
Theorem ceval_deterministic': \forall \ c \ st \ st1, (c \ / \ st \ | \ | \ st1) \rightarrow \forall \ st2, (c \ / \ st \ | \ | \ st2) \rightarrow st1 = st2. Proof. introv \ E1 \ E2. Abort.
```

Like the arguments of intros, the arguments of introv can be structured patterns.

```
Theorem exists_impl: \forall X (P: X \to Prop) (Q: Prop) (R: Prop),
```

```
\begin{array}{c} (\forall \; x, \; P \; x \to Q) \to \\ ((\exists \; x \; , \; P \; x) \to Q). \\ \text{Proof.} \\ \textit{introv} \; [x \; H2]. \; \text{eauto.} \\ \text{Qed.} \end{array}
```

Remark: the tactic *introv* works even when definitions need to be unfolded in order to reveal hypotheses.

End Introvexamples.

admit. admit.

Abort.

inverts E2. admit.

#### 4.2.2 The tactic *inverts*

```
Module INVERTSEXAMPLES.

Require Import Stlc Equiv Imp.

Import STLC.
```

The inversion tactic of Coq is not very satisfying for three reasons. First, it produces a bunch of equalities which one typically wants to substitute away, using subst. Second, it introduces meaningless names for hypotheses. Third, a call to inversion H does not remove H from the context, even though in most cases an hypothesis is no longer needed after being inverted. The tactic *inverts* address all of these three issues. It is intented to be used in place of the tactic inversion.

The following example illustrates how the tactic *inverts* H behaves mostly like **inversion** H except that it performs some substitutions in order to eliminate the trivial equalities that are being produced by **inversion**.

dup. inversion E2. subst. admit.

The tactic *inverts* H as. is like *inverts* H except that the variables and hypotheses being produced are placed in the goal rather than in the context. This strategy allows naming those new variables and hypotheses explicitly, using either intros or *introv*.

```
Theorem ceval_deterministic': \forall c \ st \ st1 \ st2,
  c / st \mid \mid st1 \rightarrow
  c / st \mid \mid st2 \rightarrow
  st1 = st2.
Proof.
  introv E1 E2. generalize dependent st2.
  (ceval_cases (induction E1) Case); intros st2 E2;
     inverts E2 as.
  Case "E_Skip". reflexivity.
  Case "E_Ass".
   subst n.
    reflexivity.
  Case "E_Seq".
   intros st3 Red1 Red2.
    assert (st' = st3) as EQ1.
       SCase "Proof of assertion". apply IHE1_1; assumption.
    subst st3.
     apply IHE1_{-}2. assumption.
  Case "E_IfTrue".
     SCase "b1 evaluates to true".
   intros.
       apply IHE1. assumption.
    SCase "b1 evaluates to false (contradiction)".
   intros.
       rewrite H in H5. inversion H5.
Abort.
```

In the particular case where a call to inversion produces a single subgoal, one can use the syntax *inverts* H as H1 H2 H3 for calling *inverts* and naming the new hypotheses H1, H2 and H3. In other words, the tactic *inverts* H as H1 H2 H3 is equivalent to *inverts* H as; *introv* H1 H2 H3. An example follows.

```
Theorem skip_left': \forall c, cequiv (SKIP;; c) c.

Proof.

introv. split; intros H.

inverts\ H as U\ V. inverts\ U. assumption. Abort.
```

A more involved example appears next. In particular, this example shows that the name of the hypothesis being inverted can be reused.

```
Example typing_nonexample_1:
  \neg \exists T,
      has_type empty
        (tabs x TBool
             (tabs y TBool
                (tapp (tvar x) (tvar y))))
         T.
Proof.
  dup 3.
  intros C. destruct C.
  inversion H. subst. clear H.
  inversion H5. subst. clear H5.
  inversion H4. subst. clear H4.
  inversion H2. subst. clear H2.
  inversion H5. subst. clear H5.
  inversion H1.
  intros C. destruct C.
  inverts H as H1.
  inverts H1 as H2.
  inverts H2 as H3.
  inverts H3 as H4.
  inverts H4.
  intros C. destruct C.
  inverts H as H.
  inverts H as H.
  inverts H as H.
  inverts H as H.
  inverts H.
Qed.
```

End INVERTSEXAMPLES.

Note: in the rare cases where one needs to perform an inversion on an hypothesis H without clearing H from the context, one can use the tactic *inverts keep* H, where the keyword keep indicates that the hypothesis should be kept in the context.

# 4.3 Tactics for n-ary connectives

Because Coq encodes conjunctions and disjunctions using binary constructors  $\land$  and  $\lor$ , working with a conjunction or a disjunction of N facts can sometimes be quite cumbursome. For this reason, "LibTactics" provides tactics offering direct support for n-ary conjunctions and disjunctions. It also provides direct support for n-ary existententials.

This section presents the following tactics:

- splits for decomposing n-ary conjunctions,
- branch for decomposing n-ary disjunctions,
- $\bullet$   $\exists$  for proving n-ary existentials.

```
Module NARYEXAMPLES.
Require Import References SfLib.
Import STLCRef.
```

#### 4.3.1 The tactic *splits*

The tactic *splits* applies to a goal made of a conjunction of n propositions and it produces n subgoals. For example, it decomposes the goal  $G1 \wedge G2 \wedge G3$  into the three subgoals G1, G2 and G3.

```
Lemma demo_splits : \forall n m, n > 0 \land n < m \land m < n+10 \land m \neq 3. Proof. intros. splits. Abort.
```

#### 4.3.2 The tactic branch

The tactic branch k can be used to prove a n-ary disjunction. For example, if the goal takes the form  $G1 \vee G2 \vee G3$ , the tactic branch 2 leaves only G2 as subgoal. The following example illustrates the behavior of the branch tactic.

```
Lemma demo_branch: \forall n \ m, n < m \lor n = m \lor m < n.

Proof.

intros.

destruct (lt_eq_lt_dec n \ m) as [[H1|H2]|H3].

branch 1. apply H1.

branch 2. apply H2.

branch 3. apply H3.

Qed.
```

#### 4.3.3 The tactic $\exists$

The library "LibTactics" introduces a notation for n-ary existentials. For example, one can write  $\exists x y z$ , H instead of  $\exists x$ ,  $\exists y$ ,  $\exists z$ , H. Similarly, the library provides a n-ary tactic  $\exists$  a b c, which is a shorthand for  $\exists$  a;  $\exists$  b;  $\exists$  c. The following example illustrates both the notation and the tactic for dealing with n-ary existentials.

```
Theorem progress: \forall ST \ t \ T \ st,
  has_type empty ST\ t\ T \rightarrow
  store\_well\_typed ST st \rightarrow
  value t \vee \exists t' st', t / st ==> t' / st'.
Proof with eauto.
  intros ST t T st Ht HST. remember (@empty ty) as Gamma.
  (has_type_cases (induction Ht) Case); subst; try solve by inversion...
  Case "T_App".
     right. destruct IHHt1 as [Ht1p \mid Ht1p]...
     SCase "t1 is a value".
       inversion Ht1p; subst; try solve by inversion.
       destruct IHHt2 as [Ht2p \mid Ht2p]...
       SSCase "t2 steps".
         inversion Ht2p as [t2' [st' Hstep]].
         \exists (tapp (tabs x \ T \ t) \ t2') st'...
Abort.
```

Remark: a similar facility for n-ary existentials is provided by the module *Coq.Program.Syntax* from the standard library. (*Coq.Program.Syntax* supports existentials up to arity 4; LibTactics supports them up to arity 10.

End NARYEXAMPLES.

# 4.4 Tactics for working with equality

One of the major weakness of Coq compared with other interactive proof assistants is its relatively poor support for reasoning with equalities. The tactics described next aims at simplifying pieces of proof scripts manipulating equalities.

This section presents the following tactics:

- asserts\_rewrite for introducing an equality to rewrite with,
- cuts\_rewrite, which is similar except that its subgoals are swapped,
- substs for improving the subst tactic,
- feguals for improving the f\_equal tactic,
- $applys_eq$  for proving P x y using an hypothesis P x z, automatically producing an equality y = z as subgoal.

Module EQUALITYEXAMPLES.

#### 4.4.1 The tactics asserts\_rewrite and cuts\_rewrite

The tactic asserts\_rewrite (E1 = E2) replaces E1 with E2 in the goal, and produces the goal E1 = E2.

```
Theorem mult_0_plus: \forall n \ m : \mathbf{nat}, (0+n) \times m = n \times m.

Proof. dup. intros n \ m. assert (H: 0+n=n). reflexivity. rewrite \to H. reflexivity. intros n \ m. asserts_rewrite (0+n=n). reflexivity. Qed.
```

The tactic  $cuts\_rewrite$  (E1 = E2) is like  $asserts\_rewrite$  (E1 = E2), except that the equality E1 = E2 appears as first subgoal.

```
Theorem mult_0_plus': \forall n \ m : \text{nat}, (0 + n) \times m = n \times m.

Proof.

intros n \ m.

cuts\_rewrite \ (0 + n = n).

reflexivity. reflexivity. Qed.
```

More generally, the tactics  $asserts\_rewrite$  and  $cuts\_rewrite$  can be provided a lemma as argument. For example, one can write  $asserts\_rewrite$  ( $\forall$  a b, a\*(S b) = a×b+a). This formulation is useful when a and b are big terms, since there is no need to repeat their statements.

```
Theorem mult_0_plus'': \forall u \ v \ w \ x \ y \ z: nat, (u + v) \times (S(w \times x + y)) = z.

Proof.

intros. asserts\_rewrite\ (\forall a \ b, \ a*(S \ b) = a \times b + a). Abort.
```

#### 4.4.2 The tactic substs

The tactic *substs* is similar to **subst** except that it does not fail when the goal contains "circular equalities", such as x = f x.

```
Lemma demo_substs : \forall x \ y \ (f: \mathbf{nat} \rightarrow \mathbf{nat}), x = f \ x \rightarrow y = x \rightarrow y = f \ x. Proof.

intros. substs. assumption. Qed.
```

#### 4.4.3 The tactic feguals

The tactic fequals is similar to f\_equal except that it directly discharges all the trivial subgoals produced. Moreover, the tactic fequals features an enhanced treatment of equalities between tuples.

```
Lemma demo_fequals: \forall (a b c d e: nat) (f: nat \rightarrow nat \rightarrow nat \rightarrow nat \rightarrow nat), a = 1 \rightarrow b = e \rightarrow e = 2 \rightarrow f a b c d = f 1 2 c 4.

Proof.

intros. fequals.

Abort.
```

#### 4.4.4 The tactic $applys\_eq$

The tactic  $applys\_eq$  is a variant of eapply that introduces equalities for subterms that do not unify. For example, assume the goal is the proposition  $P \times y$  and assume we have the assumption H asserting that  $P \times z$  holds. We know that we can prove y to be equal to z. So, we could call the tactic  $assert\_rewrite$  (y = z) and change the goal to  $P \times z$ , but this would require copy-pasting the values of y and z. With the tactic  $applys\_eq$ , we can call  $applys\_eq$  H 1, which proves the goal and leaves only the subgoal y = z. The value 1 given as argument to  $applys\_eq$  indicates that we want an equality to be introduced for the first argument of  $P \times y$  counting from the right. The three following examples illustrate the behavior of a call to  $applys\_eq$  H 1, a call to  $applys\_eq$  H 2, and a call to  $applys\_eq$  H 1 2.

```
Axiom big\_expression\_using : nat \rightarrow nat.

Lemma demo_applys_eq_1 : \forall (P:nat \rightarrow nat \rightarrow Prop) x \ y \ z,

P \ x \ (big\_expression\_using \ z) \rightarrow

P \ x \ (big\_expression\_using \ y).

Proof.

introv \ H. \ dup.

assert (Eq: big\_expression\_using \ y = big\_expression\_using \ z).

admit. rewrite Eq. apply H.

applys\_eq \ H \ 1.

admit. Qed.
```

If the mismatch was on the first argument of P instead of the second, we would have written  $applys\_eq\ H\ 2$ . Recall that the occurences are counted from the right.

```
Lemma demo_applys_eq_2 : \forall (P:nat\rightarrownat\rightarrowProp) x y z, P (big_expression_using z) x \rightarrow P (big_expression_using y) x.

Proof.

introv\ H.\ applys_eq H 2.

Abort.
```

When we have a mismatch on two arguments, we want to produce two equalities. To achieve this, we may call  $applys\_eq~H~1~2$ . More generally, the tactic  $applys\_eq$  expects a lemma and a sequence of natural numbers as arguments.

```
Lemma demo_applys_eq_3: \forall (P: \mathbf{nat} \rightarrow \mathbf{nat} \rightarrow Prop) \ x1 \ x2 \ y1 \ y2, P \ (big\_expression\_using \ x2) \ (big\_expression\_using \ y2) \rightarrow P \ (big\_expression\_using \ x1) \ (big\_expression\_using \ y1). Proof. introv \ H. \ applys\_eq \ H \ 1 \ 2. Abort. End EQUALITYEXAMPLES.
```

#### 4.5 Some convenient shorthands

This section of the tutorial introduces a few tactics that help make proof scripts shorter and more readable:

- unfolds (without argument) for unfolding the head definition,
- false for replacing the goal with **False**,
- gen as a shorthand for dependent generalize,
- skip for skipping a subgoal even if it contains existential variables,
- sort for re-ordering the proof context by moving moving all propositions at the bottom.

### 4.5.1 The tactic unfolds

```
Module UNFOLDSEXAMPLE.
Require Import Hoare.
```

The tactic *unfolds* (without any argument) unfolds the head constant of the goal. This tactic saves the need to name the constant explicitly.

```
Lemma bexp_eval_true : \forall \ b \ st, beval st \ b = \text{true} \rightarrow (\text{bassn} \ b) \ st. Proof.
intros b \ st \ Hbe. \ dup.
unfold bassn. assumption.
unfolds. assumption.
Qed.
```

Remark: contrary to the tactic hnf, which may unfold several constants, unfolds performs only a single step of unfolding.

Remark: the tactic unfolds in H can be used to unfold the head definition of the hypothesis H.

End UNFOLDSEXAMPLE.

#### 4.5.2 The tactics false and *tryfalse*

The tactic false can be used to replace any goal with False. In short, it is a shorthand for apply  $ex_falso_quodlibet$ . Moreover, false proves the goal if it contains an absurd assumption, such as False or 0 = S n, or if it contains contradictory assumptions, such as x = true and x = false.

```
Lemma demo_false : \forall \ n, \ {\bf S} \ n=1 \ \rightarrow \ n=0. Proof. intros. destruct n. reflexivity. false. Qed.
```

The tactic false can be given an argument: false H replace the goals with False and then applies H.

```
Lemma demo_false_arg : (\forall \ n, \ n < 0 \rightarrow {\sf False}) \rightarrow (3 < 0) \rightarrow 4 < 0. Proof. {\sf intros} \ H \ L. \ false \ H. \ {\sf apply} \ L. Qed.
```

The tactic *tryfalse* is a shorthand for **try solve** [false]: it tries to find a contradiction in the goal. The tactic *tryfalse* is generally called after a case analysis.

```
Lemma demo_tryfalse : \forall \ n, \ S \ n = 1 \rightarrow n = 0. Proof. intros. destruct n; \ tryfalse. reflexivity. Qed.
```

# 4.5.3 The tactic gen

The tactic gen is a shortand for generalize dependent that accepts several arguments at once. An invokation of this tactic takes the form  $gen \times y z$ .

```
\begin{array}{l} \texttt{Module GENEXAMPLE.} \\ \texttt{Require Import Stlc.} \\ \texttt{Import } STLC. \\ \texttt{Lemma substitution\_preserves\_typing} : \forall \ Gamma \ x \ U \ v \ t \ S, \\ \textbf{has\_type} \ (\texttt{extend } Gamma \ x \ U) \ t \ S \rightarrow \\ \textbf{has\_type empty} \ v \ U \rightarrow \end{array}
```

```
has_type Gamma ([x:=v]t) S.

Proof.

dup.

intros Gamma x U v t S Htypt Htypv.

generalize dependent S. generalize dependent Gamma.

induction t; intros; simpl.

admit. admit. admit. admit. admit.

introv Htypt Htypv. gen S Gamma.

induction t; intros; simpl.

admit. admit. admit. admit. admit.

Qed.

End GENEXAMPLE.
```

### 4.5.4 The tactics skip, skip\_rewrite and skip\_goal

Temporarily admitting a given subgoal is very useful when constructing proofs. It gives the ability to focus first on the most interesting cases of a proof. The tactic *skip* is like admit except that it also works when the proof includes existential variables. Recall that existential variables are those whose name starts with a question mark, e.g. ?24, and which are typically introduced by eapply.

```
Module SKIPEXAMPLE.
  Require Import Stlc.
  Import STLC.

Example astep_example1:
    (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state ==>a× (ANum 15).
Proof.
  eapply multi_step. skip. eapply multi_step. skip. skip.
Abort.
```

The tactic  $skip\ H$ : P adds the hypothesis H: P to the context, without checking whether the proposition P is true. It is useful for exploiting a fact and postponing its proof. Note:  $skip\ H$ : P is simply a shorthand for assert (H:P). skip.

```
Theorem demo_skipH : True.

Proof.

skip\ H: (\forall\ n\ m: \mathbf{nat},\ (0+n)\times m=n\times m).

Abort.

The tactic skip\_rewrite\ (E1=E2) replaces E1 with E2 in the goal, without checking that E1 is actually equal to E2.

Theorem \mathsf{mult}\_0\_\mathsf{plus}: \forall\ n\ m: \mathbf{nat},
(0+n)\times m=n\times m.
```

Proof.

```
\begin{array}{l} dup.\\ & \text{intros } n \ m.\\ & \text{assert } (H \colon 0 + n = n). \ skip. \ \text{rewrite} \to H.\\ & \text{reflexivity.}\\ & \text{intros } n \ m.\\ & skip\_rewrite \ (0 + n = n).\\ & \text{reflexivity.} \end{array}
```

Remark: the tactic *skip\_rewrite* can in fact be given a lemma statement as argument, in the same way as *asserts\_rewrite*.

The tactic  $skip\_goal$  adds the current goal as hypothesis. This cheat is useful to set up the structure of a proof by induction without having to worry about the induction hypothesis being applied only to smaller arguments. Using  $skip\_goal$ , one can construct a proof in two steps: first, check that the main arguments go through without waisting time on fixing the details of the induction hypotheses; then, focus on fixing the invokations of the induction hypothesis.

```
Theorem ceval_deterministic: \forall c \ st \ st1 \ st2,
  c / st \mid \mid st1 \rightarrow
  c / st \mid \mid st2 \rightarrow
  st1 = st2.
Proof.
  skip\_qoal.
  introv E1 E2. gen st2.
  (ceval_cases (induction E1) Case); introv E2; inverts E2 as.
  Case "E_Skip". reflexivity.
  Case "E_Ass".
    subst n.
    reflexivity.
  Case "E_Seq".
     intros st3 Red1 Red2.
    assert (st' = st3) as EQ1.
       SCase "Proof of assertion".
   eapply IH. eapply E1_{-}1. eapply Red1.
     subst st3.
   eapply IH. eapply E1_{-}2. eapply Red2.
```

#### 4.5.5 The tactic sort

Module SORTEXAMPLES.

End SKIPEXAMPLE.

Require Import Imp.

The tactic *sort* reorganizes the proof context by placing all the variables at the top and all the hypotheses at the bottom, thereby making the proof context more readable.

```
Theorem ceval_deterministic: \forall \ c \ st \ st1 \ st2,
c \ / \ st \ | \ st1 \rightarrow
c \ / \ st \ | \ st2 \rightarrow
st1 = st2.

Proof.

intros c \ st \ st1 \ st2 \ E1 \ E2.
generalize dependent st2.
(ceval\_cases \ (induction \ E1) \ Case); intros st2 \ E2; inverts \ E2.
admit. \ admit. \ sort. \ Abort.

End SORTEXAMPLES.
```

# 4.6 Tactics for advanced lemma instantiation

This last section describes a mechanism for instantiating a lemma by providing some of its arguments and leaving other implicit. Variables whose instantiation is not provided are turned into existentential variables, and facts whose instantiation is not provided are turned into subgoals.

Remark: this instantion mechanism goes far beyond the abilities of the "Implicit Arguments" mechanism. The point of the instantiation mechanism described in this section is that you will no longer need to spend time figuring out how many underscore symbols you need to write.

In this section, we'll use a useful feature of Coq for decomposing conjunctions and existentials. In short, a tactic like intros or destruct can be provided with a pattern (H1 & H2 & H3 & H4 & H5), which is a shorthand for [H1 [H2 [H3 [H4 H5]]]]]. For example, destruct ( $H_{---} Htypt$ ) as [T [Hctx Hsub]]. can be rewritten in the form destruct ( $H_{---} Htypt$ ) as (T & Hctx & Hsub).

# 4.6.1 Working of lets

When we have a lemma (or an assumption) that we want to exploit, we often need to explicitly provide arguments to this lemma, writing something like: destruct (typing\_inversion\_var\_\_ Htypt) as (T & Hctx & Hsub). The need to write several times the "underscore" symbol is tedious. Not only we need to figure out how many of them to write down, but it also makes the proof scripts look prettly ugly. With the tactic lets, one can simply write: lets (T & Hctx & Hsub): typing\_inversion\_var Htypt.

In short, this tactic *lets* allows to specialize a lemma on a bunch of variables and hypotheses. The syntax is *lets*  $\vdash$ : E0 E1 .. EN, for building an hypothesis named  $\vdash$  by applying the fact E0 to the arguments E1 to EN. Not all the arguments need to be provided, however

the arguments that are provided need to be provided in the correct order. The tactic relies on a first-match algorithm based on types in order to figure out how the to instantiate the lemma with the arguments provided.

```
Module EXAMPLESLETS. Require Import Sub. 

Axiom typing_inversion_var: \forall (G:\mathsf{context}) (x:\mathsf{id}) (T:\mathsf{ty}), has_type G (tvar x) T \rightarrow \exists S, G x = Some S \land \mathsf{subtype}\ S T.
```

First, assume we have an assumption H with the type of the form  $has\_type\ G$  (tvar x) T. We can obtain the conclusion of the lemma  $typing\_inversion\_var$  by invoking the tactics  $lets\ K$ :  $typing\_inversion\_var\ H$ , as shown next.

```
Lemma demo_lets_1: \forall (G:context) (x:id) (T:ty), has_type G (tvar x) T \rightarrow \mathsf{True}.

Proof.

intros G x T H. dup.

lets K: typing\_inversion\_var H.

destruct K as (S & Eq & Sub).

admit.

lets (S & Eq & Sub): typing\_inversion\_var H.

admit.
```

Qed.

Assume now that we know the values of G, x and T and we want to obtain S, and have  $has\_type\ G$  (tvar x) T be produced as a subgoal. To indicate that we want all the remaining arguments of  $typing\_inversion\_var$  to be produced as subgoals, we use a triple-underscore symbol  $\_\_$ . (We'll later introduce a shorthand tactic called forwards to avoid writing triple underscores.)

```
Lemma demo_lets_2 : \forall (G:context) (x:id) (T:ty), True. Proof. intros G \times T. lets (S \& Eq \& Sub): typing_inversion_var G \times T ____. Abort.
```

Usually, there is only one context G and one type T that are going to be suitable for proving **has\_type** G (tvar x) T, so we don't really need to bother giving G and T explicitly. It suffices to call lets (S & Eq & Sub): typing\_inversion\_var x. The variables G and T are then instantiated using existential variables.

```
Lemma demo_lets_3 : \forall (x:id), True.
Proof.
intros x.
lets (S \& Eq \& Sub): typing\_inversion\_var x \___.
```

Abort.

We may go even further by not giving any argument to instantiate typing\_inversion\_var. In this case, three unification variables are introduced.

```
Lemma demo_lets_4 : True. 
 Proof. lets \ (S \ \& \ Eq \ \& \ Sub) : \ typing\_inversion\_var \ \_\_\_. Abort.
```

Note: if we provide *lets* with only the name of the lemma as argument, it simply adds this lemma in the proof context, without trying to instantiate any of its arguments.

```
Lemma demo_lets_5 : True.
Proof.
  lets H: typing_inversion_var.
Abort.
```

A last useful feature of *lets* is the double-underscore symbol, which allows skipping an argument when several arguments have the same type. In the following example, our assumption quantifies over two variables  ${\sf n}$  and  ${\sf m}$ , both of type  ${\sf nat}$ . We would like  ${\sf m}$  to be instantiated as the value 3, but without specifying a value for  ${\sf n}$ . This can be achieved by writting *lets*  $K\colon H_{--}3$ .

```
Lemma demo_lets_underscore :  (\forall \ n \ m, \ n \leq m \rightarrow n < m+1) \rightarrow \mathsf{True}.  Proof. intros H.  lets \ K \colon H \ 3. \qquad \mathsf{clear} \ K.   lets \ K \colon H \ \_\_ \ 3. \qquad \mathsf{clear} \ K.  Abort.
```

Note: one can write lets: E0 E1 E2 in place of lets H: E0 E1 E2. In this case, the name H is chosen arbitrarily.

Note: the tactics *lets* accepts up to five arguments. Another syntax is available for providing more than five arguments. It consists in using a list introduced with the special symbol », for example *lets H*: (» *E0 E1 E2 E3 E4 E5 E6 E7 E8 E9* 10).

End EXAMPLESLETS.

# 4.6.2 Working of applys, forwards and specializes

The tactics applys, forwards and specializes are shorthand that may be used in place of lets to perform specific tasks.

• forwards is a shorthand for instantiating all the arguments

of a lemma. More precisely, forwards  $H: E0\ E1\ E2\ E3$  is the same as lets  $H: E0\ E1\ E2\ E3$  ..., where the triple-underscore has the same meaning as explained earlier on.

• applys allows building a lemma using the advanced instantion

mode of *lets*, and then apply that lemma right away. So, *applys E0 E1 E2 E3* is the same as *lets H: E0 E1 E2 E3* followed with eapply H and then clear H.

• specializes is a shorthand for instantiating in-place

an assumption from the context with particular arguments. More precisely, specializes H E0 E1 is the same as lets H': H E0 E1 followed with clear H and rename H' into H.

Examples of use of *applys* appear further on. Several examples of use of *forwards* can be found in the tutorial chapter UseAuto.

#### 4.6.3 Example of instantiations

Module ExamplesInstantiations.

Require Import Sub.

The following proof shows several examples where *lets* is used instead of destruct, as well as examples where *applys* is used instead of apply. The proof also contains some holes that you need to fill in as an exercise.

```
Lemma substitution_preserves_typing : \forall Gamma \ x \ U \ v \ t \ S,
     has_type (extend Gamma \ x \ U) \ t \ S \rightarrow
     has_type empty v \ U \rightarrow
     has_type Gamma ([x := v]t) S.
Proof with eauto.
  intros Gamma x U v t S Htypt Htypv.
  generalize dependent S. generalize dependent Gamma.
  (t\_cases (induction t) Case); intros; simpl.
  Case "tvar".
    rename i into y.
   lets (T\&Hctx\&Hsub): typing_inversion_var Htypt.
    unfold extend in Hctx.
    destruct (eq_id_dec x y)...
    SCase "x=y".
       subst.
       inversion Hctx; subst. clear Hctx.
      apply context_invariance with empty...
       intros x Hcontra.
         lets [T' HT']: free_in_context S empty Hcontra...
         inversion HT'.
  Case "tapp".
   admit.
```

```
Case "tabs".
    rename i into y. rename t into T1.
   lets (T2\&Hsub\&Htypt2): typing_inversion_abs Htypt.
   applys T_Sub (TArrow T1 T2)...
     apply T_Abs...
    destruct (eq_id_dec x y).
    SCase "x=y".
      eapply context_invariance...
      subst.
       intros x Hafi. unfold extend.
      destruct (eq_id_dec y x)...
    SCase "x<>y".
      apply IHt. eapply context_invariance...
       intros z Hafi. unfold extend.
      destruct (eq_id_dec y z)...
      subst. rewrite neq_id...
  Case "ttrue".
    lets: typing_inversion_true Htypt...
  Case "tfalse".
    lets: typing_inversion_false Htypt...
  Case "tif".
    lets (Htyp1&Htyp2&Htyp3): typing_inversion_if Htypt...
  Case "tunit".
   lets: typing_inversion_unit Htypt...
Qed.
```

End EXAMPLESINSTANTIATIONS.

# 4.7 Summary

In this chapter we have presented a number of tactics that help make proof script more concise and more robust on change.

- *introv* and *inverts* improve naming and inversions.
- false and *tryfalse* help discarding absurd goals.
- unfolds automatically calls unfold on the head definition.
- *gen* helps setting up goals for induction.
- cases and cases\_if help with case analysis.
- splits, branch and  $\exists$  to deal with n-ary constructs.

- asserts\_rewrite, cuts\_rewrite, substs and fequals help working with equalities.
- lets, forwards, specializes and applys provide means of very conveniently instantiating lemmas.
- applys\_eq can save the need to perform manual rewriting steps before being able to apply lemma.
- *skip*, *skip\_rewrite* and *skip\_goal* give the flexibility to choose which subgoals to try and discharge first.

Making use of these tactics can boost one's productivity in Coq proofs.

If you are interested in using LibTactics.v in your own developments, make sure you get the lastest version from: http://www.chargueraud.org/softs/tlc/.

# Chapter 5

# Library LibTactics

# 5.1 LibTactics: A Collection of Handy General-Purpose Tactics

This file contains a set of tactics that extends the set of builtin tactics provided with the standard distribution of Coq. It intends to overcome a number of limitations of the standard set of tactics, and thereby to help user to write shorter and more robust scripts.

Hopefully, Coq tactics will be improved as time goes by, and this file should ultimately be useless. In the meanwhile, serious Coq users will probably find it very useful.

The present file contains the implementation and the detailed documentation of those tactics. The SF reader need not read this file; instead, he/she is encouraged to read the chapter named UseTactics.v, which is gentle introduction to the most useful tactics from the LibTactic library.

The main features offered are:

- More convenient syntax for naming hypotheses, with tactics for introduction and inversion that take as input only the name of hypotheses of type Prop, rather than the name of all variables.
- Tactics providing true support for manipulating N-ary conjunctions, disjunctions and existentials, hidding the fact that the underlying implementation is based on binary predicates.
- Convenient support for automation: tactic followed with the symbol "~" or "\*" will call automation on the generated subgoals. Symbol "~" stands for auto and "\*" for intuition eauto. These bindings can be customized.
- Forward-chaining tactics are provided to instantiate lemmas either with variable or hypotheses or a mix of both.
- A more powerful implementation of apply is provided (it is based on refine and thus behaves better with respect to conversion).

- An improved inversion tactic which substitutes equalities on variables generated by the standard inversion mecanism. Moreover, it supports the elimination of dependently-typed equalities (requires axiom K, which is a weak form of Proof Irrelevance).
- Tactics for saving time when writing proofs, with tactics to asserts hypotheses or subgoals, and improved tactics for clearing, renaming, and sorting hypotheses.

- thanks to Georges Gonthier for the implementation trick in rapply,

Set Implicit Arguments.

# 5.2 Additional notations for Coq

#### 5.2.1 N-ary Existentials

 $\exists T1 \dots TN$ , P is a shorthand for  $\exists T1, \dots, \exists TN$ , P. Note that Coq.Program.Syntax already defines exists for arity up to 4.

```
Notation "'exists' x1 ',' P" :=
  (\exists x1, P)
  (at level 200, x1 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 ',' P" :=
  (\exists x1, \exists x2, P)
  (at level 200, x1 ident, x2 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 ',' P" :=
  (\exists x1, \exists x2, \exists x3, P)
  (at level 200, x1 ident, x2 ident, x3 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, P)
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, P)
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, \exists x6, P)
```

```
(at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident,
    right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 x7 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, \exists x6,
    \exists x7, P
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident, x7 ident,
    right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 x7 x8 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, \exists x6,
    \exists x7, \exists x8, P
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident, x7 ident, x8 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 x7 x8 x9 ',' P" :=
  (\exists \ x1 , \exists \ x2 , \exists \ x3 , \exists \ x4 , \exists \ x5 , \exists \ x6 ,
    \exists x7, \exists x8, \exists x9, P
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident, x7 ident, x8 ident, x9 ident,
    right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 x7 x8 x9 x10 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, \exists x6,
    \exists x7, \exists x8, \exists x9, \exists x10, P)
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident, x7 ident, x8 ident, x9 ident, x10 ident,
   right associativity): type_scope.
```

# 5.3 Tools for programming with Ltac

# 5.3.1 Identity continuation

```
Ltac idcont \ tt := idtac.
```

# 5.3.2 Untyped arguments for tactics

Any Coq value can be boxed into the type **Boxer**. This is useful to use Coq computations for implementing tactics.

```
Inductive Boxer : Type := | boxer : \forall (A:Type), A \rightarrow Boxer.
```

#### 5.3.3 Optional arguments for tactics

ltac\_no\_arg is a constant that can be used to simulate optional arguments in tactic definitions. Use mytactic ltac\_no\_arg on the tactic invokation, and use match arg with ltac\_no\_arg  $\Rightarrow$  .. or match type of arg with ltac\_No\_arg  $\Rightarrow$  .. to test whether an argument was provided.

```
Inductive Itac_No_arg : Set :=
    | Itac_no_arg : Itac_No_arg.
```

#### 5.3.4 Wildcard arguments for tactics

ltac\_wild is a constant that can be used to simulate wildcard arguments in tactic definitions. Notation is \_\_.

```
Inductive ltac_Wild : Set :=
    | ltac_wild : ltac_Wild.
Notation "'__'" := ltac_wild : ltac_scope.
```

 $ltac\_wilds$  is another constant that is typically used to simulate a sequence of N wildcards, with N chosen appropriately depending on the context. Notation is  $\_\_\_$ .

```
Inductive Itac_Wilds : Set :=
    | Itac_wilds : Itac_Wilds.
Notation "'-_-'" := Itac_wilds : Itac_scope.
Open Scope Itac_scope.
```

#### 5.3.5 Position markers

**ltac\_Mark** and **ltac\_mark** are dummy definitions used as sentinel by tactics, to mark a certain position in the context or in the goal.

```
Inductive Itac_Mark : Type :=
    | Itac_mark : Itac_Mark.
```

gen\_until\_mark repeats generalize on hypotheses from the context, starting from the bottom and stopping as soon as reaching an hypothesis of type Mark. If fails if Mark does not appear in the context.

```
Ltac gen\_until\_mark :=
match goal with H: ?T \vdash \_ \Rightarrow
match T with

| Itac_Mark \Rightarrow clear H
| \_ \Rightarrow generalize H; clear H; gen\_until\_mark end end.
```

intro\_until\_mark repeats intro until reaching an hypothesis of type Mark. It throws away the hypothesis Mark. It fails if Mark does not appear as an hypothesis in the goal.

```
Ltac intro\_until\_mark :=
```

```
match goal with |\vdash (ltac\_Mark \rightarrow \_) \Rightarrow intros \_ |\_ \Rightarrow intro; intro\_until\_mark end.
```

#### 5.3.6 List of arguments for tactics

A datatype of type **list Boxer** is used to manipulate list of Coq values in Itac. Notation is v1 v2 ... vN for building a list containing the values v1 through vN.

```
Require Import List.
Notation "'> '" :=
  (@nil Boxer)
  (at level 0)
  : ltac\_scope.
Notation "'\gg' v1" :=
  ((boxer v1)::nil)
  (at level 0, v1 at level 0)
  : ltac\_scope.
Notation "'> v1 v2" :=
  ((boxer v1)::(boxer v2)::nil)
  (at level 0, v1 at level 0, v2 at level 0)
  : ltac_scope.
Notation "'> v1 v2 v3" :=
  ((boxer v1)::(boxer v2)::(boxer v3)::nil)
  (at level 0, v1 at level 0, v2 at level 0, v3 at level 0)
  : ltac\_scope.
Notation "'\gg' v1 v2 v3 v4" :=
  ((boxer v1)::(boxer v2)::(boxer v3)::(boxer v4)::nil)
  (at level 0, v1 at level 0, v2 at level 0, v3 at level 0,
   v4 at level 0)
  : ltac\_scope.
Notation "'\gg' v1 v2 v3 v4 v5" :=
  ((boxer v1)::(boxer v2)::(boxer v3)::(boxer v4)::(boxer v5)::nil)
  (at level 0, v1 at level 0, v2 at level 0, v3 at level 0,
   v4 at level 0, v5 at level 0)
  : ltac\_scope.
Notation "'»' v1 v2 v3 v4 v5 v6" :=
  ((boxer v1)::(boxer v2)::(boxer v3)::(boxer v4)::(boxer v5)
   :: (boxer v6) :: nil)
  (at level 0, v1 at level 0, v2 at level 0, v3 at level 0,
   v4 at level 0, v5 at level 0, v6 at level 0)
  : ltac\_scope.
```

```
Notation "'»' v1 v2 v3 v4 v5 v6 v7" :=
     ((boxer v1)::(boxer v2)::(boxer v3)::(boxer v4)::(boxer v5)
        :: (boxer v6) :: (boxer v7) :: nil)
     (at level 0, v1 at level 0, v2 at level 0, v3 at level 0,
       v4 at level 0, v5 at level 0, v6 at level 0, v7 at level 0)
     : ltac\_scope.
Notation "'»' v1 v2 v3 v4 v5 v6 v7 v8" :=
     ((boxer v1)::(boxer v2)::(boxer v3)::(boxer v4)::(boxer v5)
        :: (boxer v6) :: (boxer v7) :: (boxer v8) :: nil)
     (at level 0, v1 at level 0, v2 at level 0, v3 at level 0.
       v4 at level 0, v5 at level 0, v6 at level 0, v7 at level 0,
       v8 at level 0)
     : ltac\_scope.
Notation "'»' v1 v2 v3 v4 v5 v6 v7 v8 v9" :=
     ((boxer v1)::(boxer v2)::(boxer v3)::(boxer v4)::(boxer v5)
        :: (boxer v6) :: (boxer v7) :: (boxer v8) :: (boxer v9) :: nil)
     (at level 0, v1 at level 0, v2 at level 0, v3 at level 0,
       v4 at level 0, v5 at level 0, v6 at level 0, v7 at level 0,
        v8 at level 0, v9 at level 0)
     : ltac\_scope.
Notation "'»' v1 v2 v3 v4 v5 v6 v7 v8 v9 v10" :=
     ((boxer v1)::(boxer v2)::(boxer v3)::(boxer v4)::(boxer v5)
        :: (boxer \ v\theta) :: (boxer \ 
     (at level 0, v1 at level 0, v2 at level 0, v3 at level 0,
        v4 at level 0, v5 at level 0, v6 at level 0, v7 at level 0,
       v8 at level 0, v9 at level 0, v10 at level 0)
     : ltac\_scope.
Notation "'»' v1 v2 v3 v4 v5 v6 v7 v8 v9 v10 v11" :=
     ((boxer v1)::(boxer v2)::(boxer v3)::(boxer v4)::(boxer v5)
        :: (boxer v6) :: (boxer v7) :: (boxer v8) :: (boxer v9) :: (boxer v10)
        :: (boxer v11) :: nil)
     (at level 0, v1 at level 0, v2 at level 0, v3 at level 0,
        v4 at level 0, v5 at level 0, v6 at level 0, v7 at level 0,
       v8 at level 0, v9 at level 0, v10 at level 0, v11 at level 0)
     : ltac\_scope.
Notation "'»' v1 v2 v3 v4 v5 v6 v7 v8 v9 v10 v11 v12" :=
     ((boxer v1)::(boxer v2)::(boxer v3)::(boxer v4)::(boxer v5)
        :: (boxer v6) :: (boxer v7) :: (boxer v8) :: (boxer v9) :: (boxer v10)
        :: (boxer v11) :: (boxer v12) :: nil)
     (at level 0, v1 at level 0, v2 at level 0, v3 at level 0,
       v4 at level 0, v5 at level 0, v6 at level 0, v7 at level 0,
        v8 at level 0, v9 at level 0, v10 at level 0, v11 at level 0,
```

```
 v12 \text{ at level } 0) \\ : ltac\_scope. \\ \text{Notation "'>' v1 v2 v3 v4 v5 v6 v7 v8 v9 v10 v11 v12 v13" := } \\ ((\text{boxer } v1) :: (\text{boxer } v2) :: (\text{boxer } v3) :: (\text{boxer } v4) :: (\text{boxer } v5) \\ :: (\text{boxer } v6) :: (\text{boxer } v7) :: (\text{boxer } v8) :: (\text{boxer } v9) :: (\text{boxer } v10) \\ :: (\text{boxer } v11) :: (\text{boxer } v12) :: (\text{boxer } v13) :: \text{nil}) \\ (\text{at level } 0, v1 \text{ at level } 0, v2 \text{ at level } 0, v3 \text{ at level } 0, \\ v4 \text{ at level } 0, v5 \text{ at level } 0, v6 \text{ at level } 0, v7 \text{ at level } 0, \\ v8 \text{ at level } 0, v9 \text{ at level } 0, v10 \text{ at level } 0, v11 \text{ at level } 0, \\ v12 \text{ at level } 0, v13 \text{ at level } 0) \\ : ltac\_scope. \\ \end{aligned}
```

The tactic  $list\_boxer\_of$  inputs a term E and returns a term of type "list boxer", according to the following rules:

- if E is already of type "list Boxer", then it returns E;
- otherwise, it returns the list (boxer E)::nil.

#### 5.3.7 Databases of lemmas

Use the hint facility to implement a database mapping terms to terms. To declare a new database, use a definition: Definition mydatabase := True.

Then, to map mykey to myvalue, write the hint: Hint Extern 1 (Register mydatabase mykey)  $\Rightarrow$  Provide myvalue.

Finally, to query the value associated with a key, run the tactic *ltac\_database\_get my-database mykey*. This will leave at the head of the goal the term *myvalue*. It can then be named and exploited using intro.

```
Definition ltac\_database\ (D:Boxer)\ (T:Boxer)\ (A:Boxer) := True.
Notation "'Register' D T" := (ltac\_database\ (boxer\ D)\ (boxer\ T)\ \_)
(at level 69, D at level 0, T at level 0).

Lemma ltac\_database\_provide: \forall\ (A:Boxer)\ (D:Boxer)\ (T:Boxer),
ltac\_database\ D\ T\ A.
Proof. split. Qed.

Ltac Provide\ T:= apply\ (@ltac\_database\_provide\ (boxer\ T)).
Ltac ltac\_database\_get\ D\ T:=
```

```
let A := fresh "TEMP" in evar (A:Boxer);
let H := fresh "TEMP" in
assert (H : ltac\_database (boxer D) (boxer T) A);
| subst A; auto
 subst A; match type of H with ltac\_database \_ \_ (boxer ?L) \Rightarrow
              generalize L end; clear H |.
```

#### 5.3.8On-the-fly removal of hypotheses

In a list of arguments » H1 H2 .. HN passed to a tactic such as lets or applys or forwards or specializes, the term rm, an identity function, can be placed in front of the name of an hypothesis to be deleted.

```
Definition rm (A:Type) (X:A) := X.
   rm_{-}term E removes one hypothesis that admits the same type as E.
Ltac rm_{-}term E :=
  let T := type \ of \ E in
  match goal with H: T \vdash \bot \Rightarrow \text{try clear } H \text{ end.}
   rm_inside E calls rm_term Ei for any subterm of the form rm Ei found in E
Ltac rm\_inside\ E :=
  let go\ E := rm\_inside\ E in
  \mathtt{match}\ E with
   rm ?X \Rightarrow rm\_term X
  |?X1?X2\Rightarrow
     go X1; go X2
  |?X1?X2?X3 \Rightarrow
     go X1; go X2; go X3
  |?X1?X2?X3?X4 \Rightarrow
     go X1; go X2; go X3; go X4
  |?X1?X2?X3?X4?X5\Rightarrow
     go X1; go X2; go X3; go X4; go X5
  |?X1?X2?X3?X4?X5?X6\Rightarrow
     qo X1; qo X2; qo X3; qo X4; qo X5; qo X6
  |?X1?X2?X3?X4?X5?X6?X7 \Rightarrow
     qo X1; qo X2; qo X3; qo X4; qo X5; qo X6; qo X7
  |?X1?X2?X3?X4?X5?X6?X7?X8 \Rightarrow
     go X1; go X2; go X3; go X4; go X5; go X6; go X7; go X8
  |?X1?X2?X3?X4?X5?X6?X7?X8?X9 \Rightarrow
     go X1; go X2; go X3; go X4; go X5; go X6; go X7; go X8; go X9
  |?X1?X2?X3?X4?X5?X6?X7?X8?X9?X10 \Rightarrow
     go X1; go X2; go X3; go X4; go X5; go X6; go X7; go X8; go X9; go X10
  |  _{-} \Rightarrow idtac
```

end.

For faster performance, one may deactivate  $rm\_inside$  by replacing the body of this definition with idtac.

```
Ltac fast\_rm\_inside\ E := rm\_inside\ E.
```

### 5.3.9 Numbers as arguments

When tactic takes a natural number as argument, it may be parsed either as a natural number or as a relative number. In order for tactics to convert their arguments into natural numbers, we provide a conversion tactic.

Require BinPos Coq.ZArith.BinInt.

```
\begin{array}{l} \operatorname{Definition}\ ltac\_nat\_from\_int\ (x:BinInt.Z):\ nat:=\\ \operatorname{match}\ x\ \operatorname{with}\\ \mid BinInt.Z0\Rightarrow 0\% nat\\ \mid BinInt.Zpos\ p\Rightarrow BinPos.nat\_of\_P\ p\\ \mid BinInt.Zneg\ p\Rightarrow 0\% nat\\ \operatorname{end}. \end{array} \begin{array}{l} \operatorname{Ltac}\ nat\_from\_number\ N:=\\ \operatorname{match}\ type\ of\ N\ \operatorname{with}\\ \mid nat\Rightarrow \operatorname{constr:}(N)\\ \mid BinInt.Z\Rightarrow \operatorname{let}\ N':=\operatorname{constr:}(ltac\_nat\_from\_int\ N)\ \operatorname{in}\ \operatorname{eval}\ \operatorname{compute}\ \operatorname{in}\ N'\\ \operatorname{end}. \end{array}
```

 $ltac\_pattern\ E$  at K is the same as pattern E at K except that K is a Coq natural rather than a Ltac integer. Syntax  $ltac\_pattern\ E$  as K in H is also available.

```
Tactic Notation "ltac_pattern" \operatorname{constr}(E) "at" \operatorname{constr}(K) := \operatorname{match} nat\_from\_number\ K with |1\Rightarrow\operatorname{pattern}\ E at 1 |2\Rightarrow\operatorname{pattern}\ E at 2 |3\Rightarrow\operatorname{pattern}\ E at 3 |4\Rightarrow\operatorname{pattern}\ E at 4 |5\Rightarrow\operatorname{pattern}\ E at 5 |6\Rightarrow\operatorname{pattern}\ E at 6 |7\Rightarrow\operatorname{pattern}\ E at 7 |8\Rightarrow\operatorname{pattern}\ E at 8 |6\operatorname{end}\ E end.

Tactic Notation "ltac_pattern" \operatorname{constr}(E) "at" \operatorname{constr}(K) "in" \operatorname{hyp}(H) := \operatorname{match} nat\_from\_number\ K with |1\Rightarrow\operatorname{pattern}\ E at 1 in H |2\Rightarrow\operatorname{pattern}\ E at 2 in H
```

```
\mid 3 \Rightarrow \text{pattern } E \text{ at } 3 \text{ in } H
\mid 4 \Rightarrow \text{pattern } E \text{ at } 4 \text{ in } H
\mid 5 \Rightarrow \text{pattern } E \text{ at } 5 \text{ in } H
\mid 6 \Rightarrow \text{pattern } E \text{ at } 6 \text{ in } H
\mid 7 \Rightarrow \text{pattern } E \text{ at } 7 \text{ in } H
\mid 8 \Rightarrow \text{pattern } E \text{ at } 8 \text{ in } H
end.
```

### 5.3.10 Testing tactics

show tac executes a tactic tac that produces a result, and then display its result.

```
Tactic Notation "show" tactic(tac) := let R := tac in pose R.
```

 $dup\ N$  produces N copies of the current goal. It is useful for building examples on which to illustrate behaviour of tactics. dup is short for  $dup\ 2$ .

```
Lemma dup\_lemma: \forall P, P \rightarrow P \rightarrow P. Proof. auto. Qed.

Ltac dup\_tactic\ N:=
match nat\_from\_number\ N with
\mid 0 \Rightarrow \text{idtac}
\mid S\ 0 \Rightarrow \text{idtac}
\mid S\ ?N' \Rightarrow \text{apply } dup\_lemma; \left[\mid dup\_tactic\ N' \mid \text{end.} \right]
Tactic Notation "dup" constr(N) := dup\_tactic\ N.
Tactic Notation "dup" := dup\ 2.
```

## 5.3.11 Check no evar in goal

```
Ltac check\_noevar\ M := match M with M \Rightarrow idtac end.

Ltac check\_noevar\_hyp\ H := let T := type\ of\ H in match type\ of\ H with T \Rightarrow idtac end.

Ltac check\_noevar\_goal := match goal with \vdash\ ?G \Rightarrow match\ G with G \Rightarrow idtac end end.
```

### 5.3.12 Tagging of hypotheses

 $get\_last\_hyp$  tt is a function that returns the last hypothesis at the bottom of the context. It is useful to obtain the default name associated with the hypothesis, e.g. intro; let  $H := get\_last\_hyp$  tt in let H' := fresh "P" H in ...

```
Ltac get\_last\_hyp \ tt := match goal with H: \_\vdash \_ \Rightarrow \mathtt{constr}:(H) end.
```

## 5.3.13 Tagging of hypotheses

*ltac\_tag\_subst* is a specific marker for hypotheses which is used to tag hypotheses that are equalities to be substituted.

```
Definition ltac\_tag\_subst (A:Type) (x:A) := x. ltac\_to\_generalize is a specific marker for hypotheses to be generalized. Definition ltac\_to\_generalize (A:Type) (x:A) := x. Ltac gen\_to\_generalize := repeat match goal with H: ltac\_to\_generalize \_ \vdash \_ \Rightarrow generalize H: clear H end. Ltac mark\_to\_generalize H := let T:=type of H in
```

## 5.3.14 Deconstructing terms

change T with  $(ltac\_to\_generalize \ T)$  in H.

 $get\_head\ E$  is a tactic that returns the head constant of the term E, ie, when applied to a term of the form  $P\ x1\ ...\ xN$  it returns P. If E is not an application, it returns E. Warning: the tactic seems to loop in some cases when the goal is a product and one uses the result of this function.

```
Ltac get\_head\ E :=  match E with |?P - - - - - - - - -| \Rightarrow constr:(P) |?P - - - - - - - - - \Rightarrow constr:(P) |?P - - - - - - \Rightarrow constr:(P) |?P - - - - - \Rightarrow constr:(P) |?P - - - - - \Rightarrow constr:(P) |?P - - \Rightarrow constr:(P)
```

```
|?P \rightarrow constr:(P)
|?P \Rightarrow constr:(P)
end.
```

 $get\_fun\_arg\ E$  is a tactic that decomposes an application term E, ie, when applied to a term of the form X1 ... XN it returns a pair made of X1 .. X(N-1) and XN.

```
Ltac get\_fun\_arg\ E:= match E with |?X1?X2?X3?X4?X5?X6?X7?X\Rightarrow constr:((X1 X2 X3 X4 X5 X6,X)) |?X1?X2?X3?X4?X5?X6?X\Rightarrow constr:((X1 X2 X3 X4 X5,X)) |?X1?X2?X3?X4?X5?X\Rightarrow constr:((X1 X2 X3 X4,X)) |?X1?X2?X3?X4?X\Rightarrow constr:((X1 X2 X3 X4,X)) |?X1?X2?X3?X4?X\Rightarrow constr:((X1 X2 X3,X)) |?X1?X2?X3?X\Rightarrow constr:((X1 X2,X)) |?X1?X2?X\Rightarrow constr:((X1,X)) |?X1?X2?X\Rightarrow constr:((X1,X)) end.
```

#### 5.3.15 Action at occurrence and action not at occurrence

 $ltac\_action\_at\ K\ of\ E\ do\ Tac$  isolates the K-th occurrence of E in the goal, setting it in the form P E for some named pattern P, then calls tactic Tac, and finally unfolds P. Syntax  $ltac\_action\_at\ K\ of\ E\ in\ H\ do\ Tac$  is also available.

```
Tactic Notation "ltac_action_at" constr(K) "of" constr(E) "do" tactic(Tac) := let p := fresh in <math>ltac\_pattern \ E at K; match goal with \vdash ?P \ \_ \Rightarrow set \ (p := P) end; Tac; unfold p; clear p.

Tactic Notation "ltac_action_at" constr(K) "of" constr(E) "in" hyp(H) "do" tactic(Tac) := let p := fresh in <math>ltac\_pattern \ E at K in H; match type \ of \ H with ?P \ \_ \Rightarrow set \ (p := P) in H end; Tac; unfold p in H; clear p.
```

protects E do Tac temporarily assigns a name to the expression E so that the execution of tactic Tac will not modify E. This is useful for instance to restrict the action of simpl.

```
Tactic Notation "protects" constr(E) "do" tactic(Tac) :=
```

```
let x := \text{fresh "TEMP" in let } H := \text{fresh "TEMP" in set } (X := E) \text{ in *; assert } (H : X = E) \text{ by reflexivity; } clearbody X; Tac; subst x.
```

Tactic Notation "protects" constr(E) "do" tactic(Tac) "/" :=  $protects\ E$  do Tac.

### 5.3.16 An alias for eq

**eq'** is an alias for **eq** to be used for equalities in inductive definitions, so that they don't get mixed with equalities generated by **inversion**.

```
Definition eq' := @eq.

Hint Unfold eq'.

Notation "\mathbf{x} '='' \mathbf{y}" := (@eq' - x \ y)

(at level 70, arguments at next level).
```

# 5.4 Backward and forward chaining

## 5.4.1 Application

rapply is a tactic similar to eapply except that it is based on the refine tactics, and thus is strictly more powerful (at least in theory:). In short, it is able to perform on-the-fly conversions when required for arguments to match, and it is able to instantiate existentials when required.

```
Tactic Notation "rapply" constr(t) :=
  first
   eexact (@t)
   refine (@t)
   refine (@t_{-})
   refine (@t \_ \_)
   refine (@t \_ \_ \_)
   refine (@t \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_ \_ \_)
   refine (@t - - - - - - -)
   refine (@t \_ \_ \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_ \_ \_ \_)
```

The tactics  $applys_N$  T, where N is a natural number, provides a more efficient way of using applys T. It avoids trying out all possible arities, by specifying explicitly the arity of function T.

```
Tactic Notation "rapply_0" constr(t) :=
```

```
refine (@t).
Tactic Notation "rapply_1" constr(t) :=
  refine (@t_{-}).
Tactic Notation "rapply_2" constr(t) :=
  refine (@t \_ \_).
Tactic Notation "rapply_3" constr(t) :=
  refine (@t \_ \_ \_).
Tactic Notation "rapply_4" constr(t) :=
  refine (@t \_ \_ \_).
Tactic Notation "rapply_5" constr(t) :=
  refine (@t \_ \_ \_ \_).
Tactic Notation "rapply_6" constr(t) :=
  refine (@t \_ \_ \_ \_ \_).
Tactic Notation "rapply_7" constr(t) :=
  refine (@t \_ \_ \_ \_ \_).
Tactic Notation "rapply_8" constr(t) :=
  refine (@t \_ \_ \_ \_ \_ \_).
Tactic Notation "rapply_9" constr(t) :=
  refine (@t \_ \_ \_ \_ \_ \_ \_).
Tactic Notation "rapply_10" constr(t) :=
  refine (@t \_ \_ \_ \_ \_ \_ \_).
   lets\_base\ H\ E adds an hypothesis H:T to the context, where T is the type of term E.
If H is an introduction pattern, it will destruct H according to the pattern.
Ltac lets\_base\ I\ E := generalize\ E; intros I.
   applys_to H E transform the type of hypothesis H by replacing it by the result of the
application of the term E to H. Intuitively, it is equivalent to lets H: (E H).
Tactic Notation "applys_to" hyp(H) constr(E) :=
  let H' := fresh in rename H into H';
  (first | lets_base H (E H')
           lets\_base\ H\ (E\ \_\ H')
           lets\_base\ H\ (E\_\_H')
           lets\_base\ H\ (E\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_\_\_H')
```

constructors calls constructor or econstructor.

 $lets\_base\ H\ (E\_\_\_\_\_H')$ 

Tactic Notation "constructors" :=

); clear H'.

```
first [constructor | econstructor]; unfold eq'.
```

#### 5.4.2 Assertions

false\_goal replaces any goal by the goal False. Contrary to the tactic false (below), it does not try to do anything else

```
Tactic Notation "false_goal" := elimtype False.
```

false\_post is the underlying tactic used to prove goals of the form False. In the default implementation, it proves the goal if the context contains False or an hypothesis of the form C x1 ... xN = D y1 ... yM, or if the congruence tactic finds a proof of  $x \neq x$  for some x.

```
Ltac false_post :=
   solve [ assumption | discriminate | congruence ].
   false replaces any goal by the goal False, and calls false_post
Tactic Notation "false" :=
   false_goal; try false_post.
```

tryfalse tries to solve a goal by contradiction, and leaves the goal unchanged if it cannot solve it. It is equivalent to try solve  $\setminus$ [ false  $\setminus$ ].

```
Tactic Notation "tryfalse" := try solve [ false ].
```

tryfalse by tac / is that same as tryfalse except that it tries to solve the goal using tactic tac if assumption and discriminate do not apply. It is equivalent to try solve \[ [ false; tac \]. Example: tryfalse by congruence/

```
Tactic Notation "tryfalse" "by" tactic(tac) "/" := try solve [ false; instantiate; tac ].
```

false T tries false; apply T, or otherwise adds T as an assumption and calls false.

```
Tactic Notation "false" \operatorname{constr}(T) "by" \operatorname{tactic}(\operatorname{tac}) "/" := \operatorname{false\_goal}; first [ \operatorname{apply}\ T | \operatorname{eapply}\ T | \operatorname{rapply}\ T]; \operatorname{instantiate};\ \operatorname{tac} | let H := \operatorname{fresh}\ \operatorname{in}\ \operatorname{lets\_base}\ H T; \operatorname{first}\ [\operatorname{discriminate}\ H | \operatorname{false}; \operatorname{instantiate};\ \operatorname{tac}\ ]]. Tactic Notation "false" \operatorname{constr}(T) :=
```

 $false\_invert$  proves any goal provided there is at least one hypothesis H in the context that can be proved absurd by calling inversion H.

```
Ltac false\_invert\_tactic := match goal with H:\_\vdash \_ \Rightarrow
```

false T by idtac/.

```
solve [inversion H
            clear H; false_invert_tactic
            fail 2 \mid end.
Tactic Notation "false_invert" :=
  false\_invert\_tactic.
   tryfalse_invert tries to prove the goal using false or false_invert, and leaves the goal
unchanged if it does not succeed.
Tactic Notation "tryfalse_invert" :=
  try solve [ false | false_invert ].
   asserts H: T is another syntax for assert (H: T), which also works with introduction
patterns. For instance, one can write: asserts [x P] (\exists n, n = 3), or asserts [H]H [n = 3]
0 \vee n = 1).
Tactic Notation "asserts" simple\_intropattern(I) ":" constr(T) :=
  let H := fresh in assert (H : T);
  [ | generalize H; clear H; intros I ].
   asserts H1 .. HN: T is a shorthand for asserts [H1 \mid [H2 \mid [... HN \mid]]]: T].
Tactic Notation "asserts" simple\_intropattern(I1)
 simple\_intropattern(I2) ":" constr(T) :=
  asserts [I1 I2]: T.
Tactic Notation "asserts" simple\_intropattern(I1)

## 5.4.3 Instantiation and forward-chaining

The instantiation tactics are used to instantiate a lemma E (whose type is a product) on some arguments. The type of E is made of implications and universal quantifications, e.g.  $\forall x, Px \rightarrow \forall yz, Qxyz \rightarrow Rz$ .

The first possibility is to provide arguments in order: first x, then a proof of P x, then y etc... In this mode, called "Args", all the arguments are to be provided. If a wildcard is provided (written  $_{--}$ ), then an existential variable will be introduced in place of the argument.

It often saves a lot of time to give only the dependent variables, (here x, y and z), and have the hypotheses generated as subgoals. In this "Vars" mode, only variables are to be provided. For instance, lemma E applied to 3 and 4 is a term of type  $\forall z$ , Q 3 4  $z \rightarrow R$  z, and P 3 is a new subgoal. It is possible to use wildcards to introduce existential variables.

However, there are situations where some of the hypotheses already exists, and it saves time to instantiate the lemma E using the hypotheses. For instance, suppose F is a term of type P 2. Then the application of E to F in this "Hyps" mode is a term of type  $\forall$  y z, Q 2 y z  $\rightarrow$  R z. Each wildcard use will generate an assertion instead, for instance if G has type Q 2 3 4, then the application of E to a wildcard and to G in mode-h is a term of type R 4, and P 2 is a new subgoal.

It is very convenient to give some arguments the lemma should be instantiated on, and let the tactic find out automatically where underscores should be insterted. Underscore arguments \_\_ are interpret as follows: an underscore means that we want to skip the argument that has the same type as the next real argument provided (real means not an underscore). If there is no real argument after underscore, then the underscore is used for the first possible argument.

The general syntax is tactic (\*\* E1 .. EN) where tactic is the name of the tactic (possibly with some arguments) and Ei are the arguments. Moreover, some tactics accept the syntax tactic E1 .. EN as short for tactic (\*\*Hnts E1 .. EN) for values of N up to 5.

Finally, if the argument EN given is a triple-underscore  $_{--}$ , then it is equivalent to providing a list of wildcards, with the appropriate number of wildcards. This means that all the remaining arguments of the lemma will be instantiated.

Tactic Notation "lets_hnf" ":" constr(T) := let H := fresh in lets_hnf H: T.
```

put X: E is a synonymous for pose (X := E). Other syntaxes are put: E.

```
\label{eq:total_constr} \begin{split} & \operatorname{Tactic \ Notation \ "put"} \ ident(X) \ ":" \ \operatorname{constr}(E) := \\ & \operatorname{pose} \ (X := E). \\ & \operatorname{Tactic \ Notation \ "put"} \ ":" \ \operatorname{constr}(E) := \\ & \operatorname{let} \ X := \operatorname{fresh} \ "X" \ \operatorname{in \ pose} \ (X := E). \end{split}
```

## 5.4.6 Application of tautologies

logic E, where E is a fact, is equivalent to assert H:E; [tauto | eapply H; clear H]. It is useful for instance to prove a conjunction [A  $\wedge$  B] by showing first [A] and then [A  $\rightarrow$  B], through the command [logic (foral A B, A  $\rightarrow$  (A  $\rightarrow$  B)  $\rightarrow$  A  $\wedge$  B)]

```
Ltac logic\_base\ E\ cont:=
```

```
assert (H:E); [ cont\ tt | eapply H; clear H ]. Tactic Notation "logic" constr(E) := logic\_base\ E ltac:(fun \_\Rightarrow tauto).
```

### 5.4.7 Application modulo equalities

The tactic *equates* replaces a goal of the form  $P \times y \times z$  with a goal of the form  $P \times ?a \times z$  and a subgoal ?a = y. The introduction of the evar ?a makes it possible to apply lemmas that would not apply to the original goal, for example a lemma of the form  $\forall n \in P \times z$  n m, because x and y might be equal but not convertible.

Usage is *equates* i1 ... *ik*, where the indices are the positions of the arguments to be replaced by evars, counting from the right-hand side. If 0 is given as argument, then the entire goal is replaced by an evar.

```
Section equatesLemma.

## 5.5 Introduction and generalization

#### 5.5.1 Introduction

*introv* is used to name only non-dependent hypothesis.

- If *introv* is called on a goal of the form  $\forall x$ , H, it should introduce all the variables quantified with a  $\forall$  at the head of the goal, but it does not introduce hypotheses that preced an arrow constructor, like in  $P \rightarrow Q$ .
- If *introv* is called on a goal that is not of the form  $\forall x, H$  nor  $P \to Q$ , the tactic unfolds definitions until the goal takes the form  $\forall x, H$  or  $P \to Q$ . If unfolding definitions does not produces a goal of this form, then the tactic *introv* does nothing at all.

```
Ltac introv\_rec :=
match goal with
|\vdash ?P \rightarrow ?Q \Rightarrow idtac
|\vdash \forall \_, \_ \Rightarrow intro; introv\_rec
|\vdash \_ \Rightarrow idtac
end.

Ltac introv\_noarg :=

Tactic Notation "introv" simple\_intropattern(I1) simple\_intropattern(I2) simple\_intropattern(I3) simple\_intropattern(I4) simple\_intropattern(I5) simple\_intropattern(I6) simple\_intropattern(I7) simple\_intropattern(I8) simple\_intropattern(I9) simple\_intropattern(I10) := introv I1; introv I2 I3 I4 I5 I6 I7 I8 I9 I10.
```

 $intros\_all$  repeats intro as long as possible. Contrary to intros, it unfolds any definition on the way. Remark that it also unfolds the definition of negation, so applying introz to a goal of the form  $\forall x, Px \rightarrow \neg Q$  will introduce x and Px and Q, and will leave False in the goal.

```
Tactic Notation "intros_all" := repeat intro. intros\_hnf \text{ introduces an hypothesis and sets in head normal form} Tactic Notation "intro\_hnf" := intro; match goal with H: \_ \vdash \_ \Rightarrow \text{hnf in } H \text{ end.}
```

#### 5.5.2 Generalization

gen X1 .. XN is a shorthand for calling generalize dependent successively on variables XN...X1. Note that the variables are generalized in reverse order, following the convention of the generalize tactic: it means that X1 will be the first quantified variable in the resulting goal.

```
Tactic Notation "gen" ident(X1) :=
  generalize dependent X1.
Tactic Notation "gen" ident(X1) ident(X2) :=
  qen X2; qen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) :=
  gen X3; gen X2; gen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) ident(X4) :=
  gen X4; gen X3; gen X2; gen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) ident(X4) ident(X5) :=
  gen X5; gen X4; gen X3; gen X2; gen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) ident(X4) ident(X5)
 ident(X6) :=
  gen X6; gen X5; gen X4; gen X3; gen X2; gen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) ident(X4) ident(X5)
 ident(X6) \ ident(X7) :=
  gen X7; gen X6; gen X5; gen X4; gen X3; gen X2; gen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) ident(X4) ident(X5)
 ident(X6) \ ident(X7) \ ident(X8) :=
  gen X8; gen X7; gen X6; gen X5; gen X4; gen X3; gen X2; gen X1.
```

```
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) ident(X4) ident(X5)
 ident(X6) \ ident(X7) \ ident(X8) \ ident(X9) :=
  gen X9; gen X8; gen X7; gen X6; gen X5; gen X4; gen X3; gen X2; gen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) ident(X4) ident(X5)
 ident(X6) \ ident(X7) \ ident(X8) \ ident(X9) \ ident(X10) :=
  gen X10; gen X9; gen X8; gen X7; gen X6; gen X5; gen X4; gen X3; gen X2; gen X1.
   generalizes X is a shorthand for calling generalize X; clear X. It is weaker than tactic
gen X since it does not support dependencies. It is mainly intended for writing tactics.
Tactic Notation "generalizes" hyp(X) :=
  generalize X; clear X.
Tactic Notation "generalizes" hyp(X1) hyp(X2) :=
  generalizes X1; generalizes X2.
Tactic Notation "generalizes" hyp(X1) hyp(X2) hyp(X3) :=
  generalizes X1 X2; generalizes X3.
Tactic Notation "generalizes" hyp(X1) hyp(X2) hyp(X3) hyp(X4) :=
  generalizes X1 X2 X3; generalizes X4.
```

### 5.5.3 Naming

sets X: E is the same as set(X := E) in \*, that is, it replaces all occurences of E by a fresh meta-variable X whose definition is E.

```
Tactic Notation "sets" ident(X) ":" constr(E) := set(X := E) in *.
```

 $def_{-}to_{-}eq\ E\ X\ H$  applies when X:=E is a local definition. It adds an assumption H: X=E and then clears the definition of X.  $def_{-}to_{-}eq_{-}sym$  is similar except that it generates the equality H: E=X.

```
Ltac def\_to\_eq\ X\ HX\ E:= assert (HX:X=E) by reflexivity; clearbody\ X. Ltac def\_to\_eq\_sym\ X\ HX\ E:= assert (HX:E=X) by reflexivity; clearbody\ X.
```

 $set\_eq \ X \ H$ : E generates the equality H: X = E, for a fresh name X, and replaces E by X in the current goal. Syntaxes  $set\_eq \ X$ : E and  $set\_eq$ : E are also available. Similarly,  $set\_eq$   $\leftarrow X \ H$ : E generates the equality H: E = X.

 $sets\_eq \ X \ HX$ : E does the same but replaces E by X everywhere in the goal.  $sets\_eq \ X$  HX: E in H replaces in H.  $set\_eq \ X \ HX$ : E in  $\vdash$  performs no substitution at all.

```
Tactic Notation "set_eq" ident(X) ident(HX) ":" constr(E) := set(X := E); def\_to\_eq \ X \ HX \ E.

Tactic Notation "set_eq" ident(X) ":" constr(E) := let \ HX := fresh \ "EQ" \ X \ in \ set\_eq \ X \ HX : E.

Tactic Notation "set_eq" ":" constr(E) := let \ X := fresh \ "X" \ in \ set\_eq \ X : E.
```

```
Tactic Notation "set_eq" "<-" ident(X) ident(HX) ":" constr(E) :=
  set (X := E); def_to_eq_sym X HX E.
Tactic Notation "set_eq" "<-" ident(X) ":" constr(E) :=
  let HX := \text{fresh "EQ" } X \text{ in } set\_eq \leftarrow X \ HX \colon E.
Tactic Notation "set_eq" "<-" ":" constr(E) :=
  let X := fresh "X" in set_eq \leftarrow X: E.
Tactic Notation "sets_eq" ident(X) ident(HX) ":" constr(E) :=
  set (X := E) in *; def_{-}to_{-}eq X HX E.
Tactic Notation "sets_eq" ident(X) ":" constr(E) :=
  let HX := fresh "EQ" X in sets_eq X HX: E.
Tactic Notation "sets_eq" ":" constr(E) :=
  let X := fresh "X" in sets_eq X: E.
Tactic Notation "sets_eq" "<-" ident(X) ident(HX) ":" constr(E) :=
  set (X := E) in *; def_{-}to_{-}eq_{-}sym \ X \ HX \ E.
Tactic Notation "sets_eq" "<-" ident(X) ":" constr(E) :=
  let HX := \text{fresh "EQ" } X \text{ in } sets\_eq \leftarrow X \ HX \colon E.
Tactic Notation "sets_eq" "<-" ":" constr(E) :=
  let X := fresh "X" in <math>sets\_eq \leftarrow X: E.
Tactic Notation "set_eq" ident(X) ident(HX) ":" constr(E) "in" hyp(H) :=
  set (X := E) in H; def_{-}to_{-}eq X HX E.
Tactic Notation "set_eq" ident(X) ":" constr(E) "in" hyp(H) :=
  let HX := fresh "EQ" X in set_eq X HX: E in H.
Tactic Notation "set_eq" ":" constr(E) "in" hyp(H) :=
  let X := fresh "X" in set_eq X: E in H.
Tactic Notation "set_eq" "<-" ident(X) ident(HX) ":" constr(E) "in" hyp(H) :=
  \operatorname{\mathsf{set}}\ (X := E) \ \operatorname{\mathsf{in}}\ H; \ def\_to\_eq\_sym\ X\ HX\ E.
Tactic Notation "set_eq" "<-" ident(X) ":" constr(E) "in" hyp(H) :=
  let HX := \text{fresh "EQ" } X \text{ in } set\_eq \leftarrow X \text{ } HX \text{: } E \text{ in } H.
Tactic Notation "set_eq" "<-" ":" constr(E) "in" hyp(H) :=
  \texttt{let}\ X := \texttt{fresh}\ "X"\ \texttt{in}\ set\_eq \leftarrow X \text{:}\ E\ \texttt{in}\ H.
Tactic Notation "set_eq" ident(X) ident(HX) ":" constr(E) "in" "|-" :=
  \mathtt{set}\ (X := E)\ \mathtt{in}\ | \text{-};\ def\_to\_eq\ X\ HX\ E.
Tactic Notation "\operatorname{set\_eq}" \operatorname{ident}(X) ":" \operatorname{constr}(E) "\operatorname{in}" "|-" :=
  let HX := fresh "EQ" X in set_eq X HX: E in \vdash.

  let X := fresh "X" in set_eq X: E in \vdash.
Tactic Notation "set_eq" "<-" ident(X) ident(HX) ":" constr(E) "in" "|-" :=
  \operatorname{\mathsf{set}}\ (X := E) \ \operatorname{\mathsf{in}}\ | \text{-}; \ def\_to\_eq\_sym}\ X\ HX\ E.
Tactic Notation "set_eq" "<-" ident(X) ":" constr(E) "in" "|-" :=
  let HX := fresh "EQ" X in <math>set\_eq \leftarrow X HX : E in \vdash.
Tactic Notation "set_eq" "<-" ":" constr(E) "in" "|-" :=
```

```
let X := fresh "X" in <math>set\_eq \leftarrow X : E in \vdash.
```

 $gen\_eq \ X$ : E is a tactic whose purpose is to introduce equalities so as to work around the limitation of the induction tactic which typically loses information.  $gen\_eq \ E$  as X replaces all occurences of term E with a fresh variable X and the equality X = E as extra hypothesis to the current conclusion. In other words a conclusion C will be turned into  $(X = E) \to C$ .  $gen\_eq$ : E and  $gen\_eq$ : E as X are also accepted.

```
Tactic Notation "gen_eq" ident(X) ":" constr(E) := let EQ := fresh in sets_eq X EQ : E ; revert EQ .
Tactic Notation "gen_eq" ":" constr(E) := let X := fresh "X" in gen_eq X : E .
Tactic Notation "gen_eq" ":" constr(E) "as" ident(X) := gen_eq X : E .
Tactic Notation "gen_eq" ident(X1) ":" constr(E1) "," ident(X2) ":" constr(E2) := gen_eq X2 : E2 ; gen_eq X1 : E1 .
Tactic Notation "gen_eq" ident(X1) ":" constr(E1) "," ident(X2) ":" constr(E2) "," ident(X3) ":" constr(E3) := gen_eq X3 : E3 ; gen_eq X2 : E2 ; gen_eq X1 : E1 .
```

sets\_let X finds the first let-expression in the goal and names its body X. sets\_eq\_let X is similar, except that it generates an explicit equality. Tactics sets\_let X in H and sets\_eq\_let X in H allow specifying a particular hypothesis (by default, the first one that contains a let is considered).

Known limitation: it does not seem possible to support naming of multiple let-in constructs inside a term, from ltac.

```
Ltac sets\_let\_base \ tac :=
   match goal with
   |\vdash \mathtt{context}[\mathtt{let} \ \_ := ?E \ \mathtt{in} \ \_] \Rightarrow tac \ E; \mathtt{cbv} \ \mathtt{zeta}
   |H: \mathtt{context}[\mathtt{let}_{-} := ?E \mathtt{in}_{-}] \vdash_{-} \Rightarrow tac \ E; \mathtt{cbv} \mathtt{zeta} \mathtt{in} \ H
   end.
Ltac sets\_let\_in\_base\ H\ tac :=
  match type of H with context[let \_ := ?E \text{ in } \_] \Rightarrow
      tac E; cbv zeta in H end.
Tactic Notation "sets_let" ident(X) :=
   sets\_let\_base\ ltac:(fun\ E \Rightarrow sets\ X:\ E).
Tactic Notation "sets_let" ident(X) "in" hyp(H) :=
   sets\_let\_in\_base\ H\ ltac:(fun\ E \Rightarrow sets\ X:\ E).
Tactic Notation "sets_eq_let" ident(X) :=
   sets\_let\_base\ ltac:(fun\ E \Rightarrow sets\_eq\ X:\ E).
Tactic Notation "sets_eq_let" ident(X) "in" hyp(H) :=
   sets\_let\_in\_base\ H\ ltac:(fun\ E \Rightarrow sets\_eq\ X:\ E).
```

## 5.6 Rewriting

### 5.6.1 Rewriting

repeat rewrite E.

Tactic Notation "rewrite\_all" constr(E) :=

 $rewrite\_all\ E$  iterates version of rewrite E as long as possible. Warning: this tactic can easily get into an infinite loop. Syntax for rewriting from right to left and/or into an hypothese is similar to the one of rewrite.

```
Tactic Notation "rewrite_all" "<-" constr(E) :=
  repeat rewrite \leftarrow E.
Tactic Notation "rewrite_all" constr(E) "in" ident(H) :=
  repeat rewrite E in H.
Tactic Notation "rewrite_all" "<-" constr(E) "in" ident(H) :=
  repeat rewrite \leftarrow E in H.
Tactic Notation "rewrite_all" constr(E) "in" "*" :=
  repeat rewrite E in *.
Tactic Notation "rewrite_all" "<-" constr(E) "in" "*" :=
  repeat rewrite \leftarrow E in *.
   asserts_rewrite E asserts that an equality E holds (generating a corresponding subgoal)
and rewrite it straight away in the current goal. It avoids giving a name to the equality and
later clearing it. Syntax for rewriting from right to left and/or into an hypothese is similar
to the one of rewrite. Note: the tactic replaces plays a similar role.
Ltac asserts\_rewrite\_tactic\ E\ action :=
  let EQ := fresh in (assert (EQ : E);
  [ idtac | action EQ; clear EQ ]).
Tactic Notation "asserts_rewrite" constr(E) :=
  asserts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite\ EQ).
Tactic Notation "asserts_rewrite" "<-" constr(E) :=
  asserts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite \leftarrow EQ).
Tactic Notation "asserts_rewrite" constr(E) "in" hyp(H) :=
  asserts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite\ EQ\ in\ H).
Tactic Notation "asserts_rewrite" "<-" constr(E) "in" hyp(H) :=
  asserts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite \leftarrow EQ\ in\ H).
   cuts_rewrite E is the same as asserts_rewrite E except that subgoals are permuted.
Ltac cuts\_rewrite\_tactic\ E\ action :=
  let EQ := fresh in (cuts EQ: E;
  [ action EQ; clear EQ | idtac ]).
Tactic Notation "cuts_rewrite" constr(E) :=
  cuts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite\ EQ).
Tactic Notation "cuts_rewrite" "<-" constr(E) :=
```

```
Tactic Notation "cuts_rewrite" constr(E) "in" hyp(H) :=
  cuts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite\ EQ\ in\ H).
Tactic Notation "cuts_rewrite" "<-" constr(E) "in" hyp(H) :=
  cuts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite \leftarrow EQ\ in\ H).
    rewrite\_except \ H \ EQ rewrites equality EQ everywhere but in hypothesis H.
Ltac rewrite\_except \ H \ EQ :=
  let K := fresh in let T := type \ of \ H in
  \operatorname{set}(K := T) \operatorname{in} H;
  rewrite EQ in *; unfold K in H; clear K.
    rewrites E at K applies when E is of the form T1 = T2 rewrites the equality E at the
K-th occurrence of T1 in the current goal. Syntaxes rewrites \leftarrow E at K and rewrites E at
K in H are also available.
Tactic Notation "rewrites" constr(E) "at" constr(K) :=
  match type \ of \ E with ?T1 = ?T2 \Rightarrow
     ltac\_action\_at \ K \ of \ T1 \ do \ (rewrite \ E) \ end.
Tactic Notation "rewrites" "<-" constr(E) "at" constr(K) :=
  match type of E with ?T1 = ?T2 \Rightarrow
     ltac\_action\_at \ K \ of \ T2 \ do \ (rewrite \leftarrow E) \ end.
Tactic Notation "rewrites" constr(E) "at" constr(K) "in" hyp(H) :=
  match type of E with ?T1 = ?T2 \Rightarrow
     ltac\_action\_at \ K \ of \ T1 \ in \ H \ do \ (rewrite \ E \ in \ H) \ end.
Tactic Notation "rewrites" "<-" constr(E) "at" constr(K) "in" hyp(H) :=
  match type of E with ?T1 = ?T2 \Rightarrow
     ltac\_action\_at \ K \ of \ T2 \ in \ H \ do \ (rewrite \leftarrow E \ in \ H) \ end.
```

 $cuts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite \leftarrow EQ).$ 

## 5.6.2 Replace

replaces E with F is the same as replace E with F except that the equality E = F is generated as first subgoal. Syntax replaces E with F in E is also available. Note that contrary to replace, replaces does not try to solve the equality by assumption. Note: replaces E with E is similar to asserts\_rewrite (E = F).

```
Tactic Notation "replaces" \operatorname{constr}(E) "with" \operatorname{constr}(F) :=  let T := \operatorname{fresh} in assert (T : E = F); [ | \operatorname{replace} E with F; \operatorname{clear} T ]. Tactic Notation "replaces" \operatorname{constr}(E) "with" \operatorname{constr}(F) "in" \operatorname{hyp}(H) :=  let T := \operatorname{fresh} in assert (T : E = F); [ | \operatorname{replace} E with F in H; \operatorname{clear} T ]. \operatorname{replaces} E at K with F replaces the K-th occurrence of E with F in the current goal. Syntax \operatorname{replaces} E at E with E in E is also available.
```

```
Tactic Notation "replaces" constr(E) "at" constr(K) "with" constr(F) := let T := fresh in assert (T: E = F); [ | rewrites T at K; clear T ].
```

```
Tactic Notation "replaces" constr(E) "at" constr(K) "with" constr(F) "in" hyp(H) := let T := fresh in assert (T: E = F); [ | rewrites\ T at K in H; clear T ].
```

### 5.6.3 Renaming

renames X1 to Y1, ..., XN to YN is a shorthand for a sequence of renaming operations rename Xi into Yi.

```
Tactic Notation "renames" ident(X1) "to" ident(Y1) :=
  rename X1 into Y1.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) :=
  renames X1 to Y1; renames X2 to Y2.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) "," ident(X3) "to" ident(Y3) :=
  renames X1 to Y1; renames X2 to Y2, X3 to Y3.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) "," ident(X3) "to" ident(Y3) ","
 ident(X_4) "to" ident(Y_4) :=
  renames X1 to Y1; renames X2 to Y2, X3 to Y3, X4 to Y4.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) "," ident(X3) "to" ident(Y3) ","
 ident(X4) "to" ident(Y4) "," ident(X5) "to" ident(Y5) :=
  renames X1 to Y1; renames X2 to Y2, X3 to Y3, X4 to Y4, X5 to Y5.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) "," ident(X3) "to" ident(Y3) ","
 ident(X4) "to" ident(Y4) "," ident(X5) "to" ident(Y5) ","
 ident(X6) "to" ident(Y6) :=
  renames X1 to Y1; renames X2 to Y2, X3 to Y3, X4 to Y4, X5 to Y5, X6 to Y6.
```

## 5.6.4 Unfolding

unfolds unfolds the head definition in the goal, i.e. if the goal has form P x1 ... xN then it calls unfold P. If the goal is an equality, it tries to unfold the head constant on the left-hand side, and otherwise tries on the right-hand side. If the goal is a product, it calls intros first.

```
Ltac apply\_to\_head\_of\ E\ cont:=
let go\ E:=
let P:=get\_head\ E\ in\ cont\ P\ in
match E\ with
|\ \forall\ \_,\_\ \Rightarrow\ intros;\ apply\_to\_head\_of\ E\ cont
|\ ?A=?B\ \Rightarrow\ first\ [\ go\ A\ |\ go\ B\ ]
```

```
|?A \Rightarrow go A
  end.
Ltac unfolds\_base :=
  match goal with \vdash ?G \Rightarrow
   apply\_to\_head\_of \ G \ ltac:(fun \ P \Rightarrow unfold \ P) \ end.
Tactic Notation "unfolds" :=
  unfolds\_base.
   unfolds in H unfolds the head definition of hypothesis H, i.e. if H has type P x1 \dots xN
then it calls unfold P in H.
Ltac unfolds\_in\_base\ H :=
  match type of H with ?G \Rightarrow
   apply\_to\_head\_of \ G \ ltac:(fun \ P \Rightarrow unfold \ P \ in \ H) \ end.
Tactic Notation "unfolds" "in" hyp(H) :=
  unfolds\_in\_base\ H.
   unfolds P1,..,PN is a shortcut for unfold P1,..,PN in *.
Tactic Notation "unfolds" reference(F1) :=
  unfold F1 in *.
Tactic Notation "unfolds" reference(F1) "," reference(F2) :=
  unfold F1,F2 in *.
Tactic Notation "unfolds" reference(F1) "," reference(F2)
 "," reference(F3) :=
  unfold F1, F2, F3 in *.

Tactic Notation "folds" constr(H1) "," constr(H2) "," constr(H3)
 "," constr(H_4) :=
  folds H1; folds H2; folds H3; folds H4.
Tactic Notation "folds" constr(H1) "," constr(H2) "," constr(H3)
 "," constr(H_4) "," constr(H_5) :=
  folds H1; folds H2; folds H3; folds H4; folds H5.
5.6.5
         Simplification
simpls is a shortcut for simpl in *.
Tactic Notation "simpls" :=
  simpl in *.
   simple P1,..,PN is a shortcut for simpl P1 in *; ..; simpl PN in *.
Tactic Notation "simpls" reference(F1) :=
  simpl F1 in *.
Tactic Notation "simpls" reference(F1) "," reference(F2) :=
  simpls F1; simpls F2.
Tactic Notation "simpls" reference(F1) "," reference(F2)
 "," reference(F3) :=
  simpls F1; simpls F2; simpls F3.
Tactic Notation "simpls" reference(F1) "," reference(F2)
 "," reference(F3) "," reference(F4) :=
  simpls F1; simpls F2; simpls F3; simpls F4.
   unsimpl E replaces all occurrence of X by E, where X is the result which the tactic simpl
would give when applied to E. It is useful to undo what simpl has simplified too far.
Tactic Notation "unsimpl" constr(E) :=
  let F := (eval simpl in E) in change F with E.
   unsimpl\ E in H is similar to unsimpl\ E but it applies inside a particular hypothesis H.
Tactic Notation "unsimpl" constr(E) "in" hyp(H) :=
  let F := (eval simpl in E) in change F with E in H.
   unsimpl\ E in * applies unsimpl\ E everywhere possible. unsimpls\ E is a synonymous.
Tactic Notation "unsimpl" constr(E) "in" "*" :=
  let F := (\text{eval simpl in } E) in change F with E in *.
Tactic Notation "unsimpls" constr(E) :=
```

```
unsimpl E in *.
```

 $nosimpl\ t$  protects the Coq term t against some forms of simplification. See Gonthier's work for details on this trick.

```
Notation "'nosimpl' t" := (match tt with tt \Rightarrow t end) (at level 10).
```

#### 5.6.6 Evaluation

Tactic Notation "hnfs" := hnf in \*.

### 5.6.7 Substitution

substs does the same as subst, except that it does not fail when there are circular equalities in the context.

```
Tactic Notation "substs" := repeat (match goal with H: ?x = ?y \vdash \_ \Rightarrow first [ subst x | subst y ] end).
```

Implementation of *substs below*, which allows to call **subst** on all the hypotheses that lie beyond a given position in the proof context.

```
Ltac substs\_below\ limit :=
match goal with H\colon ?T \vdash \_\Rightarrow
match T with
\mid limit \Rightarrow \text{idtac}
\mid ?x = ?y \Rightarrow
first [ subst\ x;\ substs\_below\ limit
\mid subst\ y;\ substs\_below\ limit
\mid generalizes\ H;\ substs\_below\ limit;\ intro\ ]
end end.
```

substs below body E applies subst on all equalities that appear in the context below the first hypothesis whose body is E. If there is no such hypothesis in the context, it is equivalent to subst. For instance, if H is an hypothesis, then substs below H will substitute equalities below hypothesis H.

```
Tactic Notation "substs" "below" "body" constr(M) := substs\_below M.
```

substs below H applies subst on all equalities that appear in the context below the hypothesis named H. Note that the current implementation is technically incorrect since it will confuse different hypotheses with the same body.

```
Tactic Notation "substs" "below" hyp(H) := match type \ of \ H with ?M \Rightarrow substs \ below \ body \ M end.
```

 $subst\_hyp\ H$  substitutes the equality contained in H. The behaviour is extended in Lib-Data -TODO

```
Ltac subst\_hyp\_base\ H:=
  match type of H with
  |?x = ?y \Rightarrow first [subst x | subst y]
  end.
Tactic Notation "subst_hyp" hyp(H) := subst_hyp_base\ H.
   intro_subst is a shorthand for intro H; subst_hyp H: it introduces and substitutes the
equality at the head of the current goal.
Tactic Notation "intro_subst" :=
  let H := fresh "TEMP" in intros H; subst\_hyp H.
   subst\_local substitutes all local definition from the context
Ltac subst\_local :=
  repeat match goal with H:=_{-}\vdash_{-}\Rightarrow subst H end.
   subst_{-}eq E takes an equality x = t and replace x with t everywhere in the goal
Ltac subst_eq_base E :=
  let H := fresh "TEMP" in lets H: E; subst_hyp H.
Tactic Notation "subst_eq" constr(E) :=
  subst_eq_base E.
```

## 5.6.8 Tactics to work with proof irrelevance

Require Import ProofIrrelevance.

 $pi\_rewrite\ E$  replaces E of type Prop with a fresh unification variable, and is thus a practical way to exploit proof irrelevance, without writing explicitly rewrite ( $proof\_irrelevance\ E\ E'$ ). Particularly useful when E' is a big expression.

```
Ltac pi\_rewrite\_base\ E\ rewrite\_tac:=
let E':= fresh in let T:= type\ of\ E in evar (E':T);
rewrite\_tac\ (@proof\_irrelevance\ \_E\ E'); subst E'.

Tactic Notation "pi\_rewrite" constr(E):=
pi\_rewrite\_base\ E\ ltac:(fun\ X\Rightarrow rewrite\ X).

Tactic Notation "pi\_rewrite" constr(E) "in" hyp(H):=
pi\_rewrite\_base\ E\ ltac:(fun\ X\Rightarrow rewrite\ X\ in\ H).
```

## 5.6.9 Proving equalities

fequal is a variation on f\_equal which has a better behaviour on equalities between n-ary tuples.

```
Ltac fequal\_base :=
  let go := f_equal; [fequal_base] in
  match goal with
  |\vdash(-,-,-)=(-,-,-)\Rightarrow go
   |\vdash(\_,\_,\_,\_)=(\_,\_,\_)\Rightarrow go
  |\vdash(-,-,-,-)=(-,-,-,-)\Rightarrow go
  | \vdash (\_,\_,\_,\_,\_) = (\_,\_,\_,\_,\_) \Rightarrow go
  end.
Tactic Notation "fequal" :=
  fequal\_base.
   fequals is the same as fequal except that it tries and solve all trivial subgoals, using
reflexivity and congruence (as well as the proof-irrelevance principle). fequals applies to
goals of the form f x1 ... xN = f y1 ... yN and produces some subgoals of the form xi = yi).
Ltac fegual\_post :=
  first [reflexivity | congruence | apply proof_irrelevance | idtac ].
Tactic Notation "feguals" :=
  fequal; fequal_post.
   fequals_rec calls fequals recursively. It is equivalent to repeat (progress fequals).
Tactic Notation "feguals_rec" :=
  repeat (progress feguals).
```

### 5.7 Inversion

#### 5.7.1 Basic inversion

invert keep H is same to inversion H except that it puts all the facts obtained in the goal. The keyword keep means that the hypothesis H should not be removed.

```
Tactic Notation "invert" "keep" hyp(H) := pose \ ltac\_mark; inversion H; \ gen\_until\_mark.
```

invert keep H as X1 .. XN is the same as inversion H as ... except that only hypotheses which are not variable need to be named explicitly, in a similar fashion as introv is used to name only hypotheses.

```
Tactic Notation "invert" "keep" hyp(H) "as" simple\_intropattern(I1) := invert keep H; introv I1.

Tactic Notation "invert" "keep" hyp(H) "as" simple\_intropattern(I1) simple\_intropattern(I2) := invert keep H; introv I1 I2.

Tactic Notation "invert" "keep" hyp(H) "as" simple\_intropattern(I1)
```

```
simple\_intropattern(I2) \ simple\_intropattern(I3) := invert \ keep \ H; introv \ I1 \ I2 \ I3.
```

invert H is same to inversion H except that it puts all the facts obtained in the goal and clears hypothesis H. In other words, it is equivalent to invert keep H; clear H.

```
Tactic Notation "invert" hyp(H) := invert \ keep \ H; clear H.
```

invert H as X1 .. XN is the same as invert keep H as X1 .. XN but it also clears hypothesis H.

```
Tactic Notation "invert_tactic" hyp(H) tactic(tac) := let H' := fresh in rename H into H' ; tac H' ; clear H' .
Tactic Notation "invert" hyp(H) "as" simple\_intropattern(I1) := invert_tactic H (fun H \Rightarrow invert keep H as I1).
Tactic Notation "invert" hyp(H) "as" simple\_intropattern(I1) simple\_intropattern(I2) := invert_tactic H (fun H \Rightarrow invert keep H as I1 I2).
Tactic Notation "invert" hyp(H) "as" simple\_intropattern(I1) simple\_intropattern(I2) simple\_intropattern(I3) := invert_tactic H (fun H \Rightarrow invert keep H as I1 I2 I3).
```

#### 5.7.2 Inversion with substitution

Our inversion tactics is able to get rid of dependent equalities generated by inversion, using proof irrelevance.

```
Axiom inj_pair2: \forall (U: Type) (P: U \rightarrow Type) (p: U) (x y: P p),
         existT \ P \ p \ x = existT \ P \ p \ y \rightarrow x = y.
Ltac inverts\_tactic\ H\ i1\ i2\ i3\ i4\ i5\ i6:=
  let rec qo i1 i2 i3 i4 i5 i6 :=
     match goal with
     \mid \vdash (ltac\_Mark \rightarrow \_) \Rightarrow intros \_
     |\vdash (?x = ?y \rightarrow \_) \Rightarrow \text{let } H := \text{fresh in intro } H;
                                     first [ subst x | subst y ];
                                     go i1 i2 i3 i4 i5 i6
     |\vdash (existT?P?p?x = existT?P?p?y \rightarrow \_) \Rightarrow
            let H := fresh in intro H;
            generalize (@inj_pair2 - P p x y H);
            clear H; go i1 i2 i3 i4 i5 i6
     |\vdash(?P\rightarrow?Q)\Rightarrow i1; go\ i2\ i3\ i4\ i5\ i6\ ltac:(intro)
     |\vdash(\forall\_,\_)\Rightarrow intro; go i1 i2 i3 i4 i5 i6
     end in
  generalize ltac_mark; invert keep H; go i1 i2 i3 i4 i5 i6;
  unfold eq in *.
```

inverts keep H is same to invert keep H except that it applies subst to all the equalities generated by the inversion.

```
Tactic Notation "inverts" "keep" hyp(H) :=
  inverts_tactic H ltac:(intro) ltac:(intro) ltac:(intro)
                     ltac:(intro) ltac:(intro) ltac:(intro).
   inverts keep H as X1 .. XN is the same as invert keep H as X1 .. XN except that it
applies subst to all the equalities generated by the inversion
Tactic Notation "inverts" "keep" hyp(H) "as" simple\_intropattern(I1) :=
  inverts_tactic H ltac:(intros I1)
   ltac:(intro) ltac:(intro) ltac:(intro) ltac:(intro).

  injection H; intros X1 \ X2 \ X3.
```

```
Tactic Notation "inject" hyp(H) "as" ident(X1) ident(X2) ident(X3) ident(X4) := injection H; intros X1 X2 X3 X4.

Tactic Notation "inject" hyp(H) "as" ident(X1) ident(X2) ident(X3) ident(X4) ident(X5) := injection H; intros X1 X2 X3 X4 X5.
```

# 5.7.4 Inversion and injection with substitution —rough implementation

The tactics *inversions* and *injections* provided in this section are similar to *inverts* and *injects* except that they perform substitution on all equalities from the context and not only the ones freshly generated. The counterpart is that they have simpler implementations.

inversions keep H is the same as inversions H but it does not clear hypothesis H.

```
Tactic Notation "inversions" "keep" hyp(H) := inversion H; subst.
```

inversions H is a shortcut for inversion H followed by subst and clear H. It is a rough implementation of inverts keep H which behave badly when the proof context already contains equalities. It is provided in case the better implementation turns out to be too slow.

```
Tactic Notation "inversions" hyp(H) := inversion H; subst; clear H.
```

injections keep H is the same as injection H followed by intros and subst. It is a rough implementation of injects keep H which behave badly when the proof context already contains equalities, or when the goal starts with a forall or an implication.

```
Tactic Notation "injections" "keep" hyp(H) := injection H; intros; subst.
```

injections H is the same as injection H followed by intros and clear H and subst. It is a rough implementation of injects keep H which behave badly when the proof context already contains equalities, or when the goal starts with a forall or an implication.

```
Tactic Notation "injections" "keep" hyp(H) := injection H; clear H; intros; subst.
```

#### 5.7.5 Case analysis

cases is similar to case\_eq E except that it generates the equality in the context and not in the goal, and generates the equality the other way round. The syntax cases E as H allows specifying the name H of that hypothesis.

```
Tactic Notation "cases" constr(E) "as" ident(H) := let X := fresh "TEMP" in
```

```
set (X := E) in *; def_{-}to_{-}eq_{-}sym \ X \ H \ E;
  destruct X.
Tactic Notation "cases" constr(E) :=
  let x := fresh "Eq" in cases E as H.
    case_if_post is to be defined later as a tactic to clean up goals.
Ltac case\_if\_post := idtac.
    case\_if looks for a pattern of the form if ?B then ?E1 else ?E2 in the goal, and perform
a case analysis on B by calling destruct B. It looks in the goal first, and otherwise in the
first hypothesis that contains and if statement. case_if in H can be used to specify which
hypothesis to consider. Syntaxes case\_if as Eq and case\_if in H as Eq allows to name the
hypothesis coming from the case analysis.
Ltac case\_if\_on\_tactic \ E \ Eq :=
  match type \ of \ E with
  \mid \{\_\} + \{\_\} \Rightarrow \text{destruct } E \text{ as } [Eq \mid Eq]
  \mid \_ \Rightarrow \mathtt{let}\ X := \mathtt{fresh}\ \mathtt{in}
           sets\_eq \leftarrow X \ Eq: \ E;
           destruct X
  end; case\_if\_post.
Tactic Notation "case_if_on" constr(E) "as" simple_intropattern(Eq) :=
  case\_if\_on\_tactic \ E \ Eq.
Tactic Notation "case_if" "as" simple\_intropattern(Eq) :=
  match goal with
  \vdash context [if ?B then _ else _] \Rightarrow case\_if\_on\ B as Eq
  | K: context [if ?B then _ else _] \vdash _ \Rightarrow case_if_on B as Eq
Tactic Notation "case_if" "in" hyp(H) "as" simple_intropattern(Eq) :=
  match type\ of\ H with context |if ?B then \_ else \_| \Rightarrow
     case\_if\_on \ B \ as \ Eq \ end.
Tactic Notation "case_if" :=
  let Eq := fresh in <math>case\_if as Eq.
Tactic Notation "case_if" "in" hyp(H) :=
  let Eq := fresh in case_if in H as Eq.
    cases_if is similar to case_if with two main differences: if it creates an equality of the
form x = y or x == y, it substitutes it in the goal
Ltac cases\_if\_on\_tactic \ E \ Eq :=
  match type \ of \ E with
  |\{-\}+\{-\}| \Rightarrow \text{destruct } E \text{ as } [Eq|Eq]; \text{try } subst\_hyp \ Eq
  \mid \_ \Rightarrow \mathtt{let}\ X := \mathtt{fresh}\ \mathtt{in}
```

 $sets\_eq \leftarrow X \ Eq: \ E;$ 

```
destruct X
  end; case_if_post.
Tactic Notation "cases_if_on" constr(E) "as" simple_intropattern(Eq) :=
  cases\_if\_on\_tactic \ E \ Eq.
Tactic Notation "cases_if" "as" simple\_intropattern(Eq) :=
  match goal with
  \vdash context [if ?B then _ else _] \Rightarrow case\_if\_on\ B as Eq
  | K: context [if ?B then _ else _] \vdash _ \Rightarrow case\_if\_on B as Eq
Tactic Notation "cases_if" "in" hyp(H) "as" simple\_intropattern(Eq) :=
  match type of H with context [if ?B then \_ else \_] \Rightarrow
    cases\_if\_on \ B as Eq end.
Tactic Notation "cases_if" :=
  let Eq := fresh in cases_if as Eq.
Tactic Notation "cases_if" "in" hyp(H) :=
  let Eq := fresh in cases_if in H as Eq.
   destruct_if looks for a pattern of the form if ?B then ?E1 else ?E2 in the goal, and
perform a case analysis on B by calling destruct B. It looks in the goal first, and otherwise
in the first hypothesis that contains and if statement.
Ltac destruct\_if\_post := tryfalse.
Tactic Notation "destruct_if"
 "as" simple\_intropattern(Eq1) simple\_intropattern(Eq2) :=
  match goal with
  \vdash context [if ?B then _ else _] \Rightarrow destruct B as [Eq1|Eq2]
  | K: context [if ?B then _ else _] \vdash _ \Rightarrow destruct B as [Eq1|Eq2]
  end;
  destruct\_if\_post.
Tactic Notation "destruct_if" "in" hyp(H)
 "as" simple\_intropattern(Eq1) simple\_intropattern(Eq2) :=
  match type of H with context |if ?B then \_ else \_| \Rightarrow
    destruct B as [Eq1|Eq2] end;
  destruct\_if\_post.
Tactic Notation "destruct_if" "as" simple\_intropattern(Eq) :=
  destruct\_if as Eq Eq.
Tactic Notation "destruct_if" "in" hyp(H) "as" simple\_intropattern(Eq) :=
  destruct\_if in H as Eq Eq.
Tactic Notation "destruct_if" :=
  let Eq := fresh "C" in destruct\_if as Eq Eq.
Tactic Notation "destruct_if" "in" hyp(H) :=
```

```
let Eq := fresh "C" in destruct\_if in H as Eq Eq.
```

 $destruct\_head\_match$  performs a case analysis on the argument of the head pattern matching when the goal has the form match ?E with ... or match ?E with ... = \_ or \_ = match ?E with .... Due to the limits of Ltac, this tactic will not fail if a match does not occur. Instead, it might perform a case analysis on an unspecified subterm from the goal. Warning: experimental.

```
Ltac find\_head\_match \ T :=
  match T with context [?E] \Rightarrow
     {\tt match}\ T\ {\tt with}
     \mid E \Rightarrow \text{fail } 1
     | \_ \Rightarrow constr:(E)
     end
  end.
Ltac\ destruct\_head\_match\_core\ cont:=
  match goal with
  |\vdash ?T1 = ?T2 \Rightarrow \texttt{first} \mid \texttt{let} \ E := find\_head\_match \ T1 \ \texttt{in} \ cont \ E
                                    | let E:=find\_head\_match T2 in cont E |
  |\vdash ?T1 \Rightarrow \text{let } E := find\_head\_match \ T1 \ \text{in } cont \ E
  end:
  destruct\_if\_post.
Tactic Notation "destruct_head_match" "as" simple\_intropattern(I) :=
  destruct\_head\_match\_core\ ltac:(fun\ E \Rightarrow destruct\ E\ as\ I).
Tactic Notation "destruct_head_match" :=
   destruct\_head\_match\_core ltac:(fun E \Rightarrow destruct E).
    cases' E is similar to case_eq E except that it generates the equality in the context and
not in the goal. The syntax cases E as H allows specifying the name H of that hypothesis.
Tactic Notation "cases'" constr(E) "as" ident(H) :=
  let X := fresh "TEMP" in
  set (X := E) in *; def_-to_-eq X H E;
  destruct X.
Tactic Notation "cases'" constr(E) :=
  let x := fresh "Eq" in cases' E as H.
    cases_if' is similar to cases_if except that it generates the symmetric equality.
Ltac cases\_if\_on' E Eq :=
  match type \ of \ E with
   \mid \{\_\} + \{\_\} \Rightarrow \mathtt{destruct} \,\, E \,\, \mathtt{as} \,\, [Eq|Eq]; \, \mathtt{try} \,\, subst\_hyp \,\, Eq
  \mid \_ \Rightarrow \mathtt{let}\ X := \mathtt{fresh}\ \mathtt{in}
            sets\_eq \ X \ Eq: \ E;
            destruct X
```

```
end; case\_if\_post.

Tactic Notation "cases\_if'" "as" simple\_intropattern(Eq) :=  match goal with |\vdash context[if?B then\_else\_] \Rightarrow cases\_if\_on' B Eq  |K: context[if?B then\_else\_] \vdash \_ \Rightarrow cases\_if\_on' B Eq  end.

Tactic Notation "cases\_if'" :=  let Eq :=  fresh in cases\_if' as Eq.
```

#### 5.8 Induction

inductions E is a shorthand for dependent induction E. inductions E gen X1 .. XN is a shorthand for dependent induction E generalizing X1 .. XN.

```
Require Import Coq. Program. Equality.
Ltac inductions\_post :=
  unfold eq in *.
Tactic Notation "inductions" ident(E) :=
  dependent induction E; inductions\_post.
Tactic Notation "inductions" ident(E) "gen" ident(X1) :=
  dependent induction E generalizing X1; inductions\_post.
Tactic Notation "inductions" ident(E) "gen" ident(X1) ident(X2) :=
  dependent induction E generalizing X1 X2; inductions\_post.
Tactic Notation "inductions" ident(E) "gen" ident(X1) ident(X2)
 ident(X3) :=
  dependent induction E generalizing X1 X2 X3; inductions\_post.
Tactic Notation "inductions" ident(E) "gen" ident(X1) ident(X2)
 ident(X3) \ ident(X4) :=
  dependent induction E generalizing X1 X2 X3 X4; inductions_post.
Tactic Notation "inductions" ident(E) "gen" ident(X1) ident(X2)
 ident(X3) \ ident(X4) \ ident(X5) :=
  dependent induction E generalizing X1 X2 X3 X4 X5; inductions_post.
Tactic Notation "inductions" ident(E) "gen" ident(X1) ident(X2)
 ident(X3) \ ident(X4) \ ident(X5) \ ident(X6) :=
  dependent induction E generalizing X1 X2 X3 X4 X5 X6; inductions_post.
Tactic Notation "inductions" ident(E) "gen" ident(X1) ident(X2)
 ident(X3) \ ident(X4) \ ident(X5) \ ident(X6) \ ident(X7) :=
  dependent induction E generalizing X1 X2 X3 X4 X5 X6 X7; inductions_post.
Tactic Notation "inductions" ident(E) "gen" ident(X1) ident(X2)
 ident(X3) \ ident(X4) \ ident(X5) \ ident(X6) \ ident(X7) \ ident(X8) :=
  {\tt dependent\ induction}\ E\ generalizing\ X1\ X2\ X3\ X4\ X5\ X6\ X7\ X8;\ inductions\_post.
```

induction\_wf IH: E X is used to apply the well-founded induction principle, for a given well-founded relation. It applies to a goal PX where PX is a proposition on X. First, it sets up the goal in the form (fun  $a \Rightarrow Pa$ ) X, using pattern X, and then it applies the well-founded induction principle instantiated on E, where E is a term of type well\_founded R, and R is a binary relation. Syntaxes induction\_wf: E X and induction\_wf E X.

```
Tactic Notation "induction_wf" ident(IH) ":" constr(E) \ ident(X) :=  pattern X; apply (well\_founded\_ind \ E); clear \ X; intros \ X \ IH. Tactic Notation "induction_wf" ":" constr(E) \ ident(X) :=  let IH :=  fresh "IH" in induction\_wf \ IH : E \ X. Tactic Notation "induction_wf" ":" constr(E) \ ident(X) :=  induction\_wf : E \ X.
```

## 5.9 Decidable equality

decides\_equality is the same as decide equality excepts that it is able to unfold definitions at head of the current goal.

```
Ltac decides_equality_tactic :=
  first [ decide equality | progress(unfolds); decides_equality_tactic ].
Tactic Notation "decides_equality" :=
  decides_equality_tactic.
```

## 5.10 Equivalence

iff H can be used to prove an equivalence  $P \leftrightarrow Q$  and name H the hypothesis obtained in each case. The syntaxes iff and iff H1 H2 are also available to specify zero or two names. The tactic iff  $\leftarrow H$  swaps the two subgoals, i.e. produces  $(Q \rightarrow P)$  as first subgoal.

```
Lemma iff\_intro\_swap: \forall (P\ Q: \operatorname{Prop}), \ (Q \to P) \to (P \to Q) \to (P \leftrightarrow Q). Proof. intuition. Qed.

Tactic Notation "iff" simple\_intropattern(H1) simple\_intropattern(H2) := \operatorname{split}; [\operatorname{intros}\ H1 \mid \operatorname{intros}\ H2].

Tactic Notation "iff" simple\_intropattern(H) := iff\ H\ H.

Tactic Notation "iff" := \operatorname{let}\ H:=\operatorname{fresh}\ "H" in iff\ H.

Tactic Notation "iff" := \operatorname{let}\ H:=\operatorname{fresh}\ "H" in iff\ H.

Tactic Notation "iff" := \operatorname{let}\ H:=\operatorname{fresh}\ "H" in := \operatorname{let}\ H:=\operatorname{fintro}\ H1 | := \operatorname{let}\ H:=\operatorname{fintro}\ H2 ].

Tactic Notation "iff" := \operatorname{let}\ H.

Tactic Notation "iff" := \operatorname{let}\ H.

Tactic Notation "iff" := \operatorname{let}\ H.
```

## 5.11 N-ary Conjunctions and Disjunctions

```
N-ary Conjunctions Splitting in Goals
    Underlying implementation of splits.
Ltac splits\_tactic N :=
   \mathtt{match}\ N with
   | O \Rightarrow fail
    S O \Rightarrow idtac
   \mid S ? N' \Rightarrow \text{split}; \mid splits\_tactic N' \mid
   end.
Ltac\ unfold\_goal\_until\_conjunction :=
   match goal with
   |\vdash \_ \land \_ \Rightarrow idtac
   \bot \Rightarrow progress(unfolds); unfold\_goal\_until\_conjunction
   end.
Ltac qet\_term\_conjunction\_arity T :=
   {\tt match}\ T\ {\tt with}
   | \_ \land \_ \land \_ \land \_ \land \_ \land \_ \land \_ \Rightarrow constr:(8)
    - \land - \land - \land - \land - \land - \land - \Rightarrow constr:(7)
    \_ \land \_ \land \_ \land \_ \land \_ \land \_ \Rightarrow constr:(6)
    \_ \land \_ \land \_ \land \_ \land \_ \Rightarrow constr:(5)
    \_ \land \_ \land \_ \land \_ \Rightarrow constr:(4)
    \_ \land \_ \land \_ \Rightarrow constr:(3)
    \_ \land \_ \Rightarrow constr:(2)
    \_ \rightarrow ?T' \Rightarrow get\_term\_conjunction\_arity\ T'
   | \_ \Rightarrow let P := get\_head T in
              \mathtt{let}\ T' := \mathtt{eval}\ \mathtt{unfold}\ P\ \mathtt{in}\ T\ \mathtt{in}
              match T' with
              \mid T \Rightarrow \text{fail } 1
              | \_ \Rightarrow get\_term\_conjunction\_arity T'
              end
   end.
Ltac qet\_qoal\_conjunction\_arity :=
   match goal with \vdash ?T \Rightarrow get\_term\_conjunction\_arity\ T end.
     splits applies to a goal of the form (T1 \wedge ... \wedge TN) and destruct it into N subgoals T1
.. TN. If the goal is not a conjunction, then it unfolds the head definition.
Tactic Notation "splits" :=
```

```
unfold\_goal\_until\_conjunction;
let N := get\_goal\_conjunction\_arity in splits\_tactic\ N.
```

splits N is similar to splits, except that it will unfold as many definitions as necessary to obtain an N-ary conjunction.

```
Tactic Notation "splits" constr(N) := let N := nat\_from\_number \ N in splits\_tactic \ N.
```

 $splits\_all$  will recursively split any conjunction, unfolding definitions when necessary. Warning: this tactic will loop on goals of the form  $well\_founded$  **R**. Todo: fix this

```
Ltac splits\_all\_base := \texttt{repeat split}.
```

```
Tactic Notation "splits_all" := splits\_all\_base.
```

N-ary Conjunctions Deconstruction Underlying implementation of *destructs*.

 $Ltac \ destructs\_conjunction\_tactic \ N \ T :=$ 

```
\begin{array}{l} \operatorname{match} \ N \ \operatorname{with} \\ | \ 2 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ ?] \\ | \ 3 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ ?]] \\ | \ 4 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ [? \ ?]]]] \\ | \ 5 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ [? \ [? \ ?]]]]] \\ | \ 6 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ [? \ [? \ [? \ ?]]]]]] \\ | \ 7 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ [? \ [? \ [? \ ?]]]]]] \\ | \ \operatorname{end}. \end{array}
```

destructs T allows destructing a term T which is a N-ary conjunction. It is equivalent to destruct T as (H1 ... HN), except that it does not require to manually specify N different names.

```
Tactic Notation "destructs" constr(T) := let TT := type \ of \ T in let N := get\_term\_conjunction\_arity \ TT in destructs\_conjunction\_tactic \ N \ T.
```

destructs N T is equivalent to destruct T as (H1 ... HN), except that it does not require to manually specify N different names. Remark that it is not restricted to N-ary conjunctions.

```
Tactic Notation "destructs" constr(N) constr(T) := let N := nat\_from\_number N in destructs\_conjunction\_tactic N T.

Proving goals which are N-ary disjunctions
```

Underlying implementation of branch.

```
Ltac branch\_tactic \ K \ N :=
   match constr:(K,N) with
   |(-,0) \Rightarrow \text{fail } 1
   \mid (0,\_) \Rightarrow \texttt{fail} \ 1
   |(1,1) \Rightarrow \text{idtac}
   |(1,\_) \Rightarrow \text{left}
   (S?K', S?N') \Rightarrow right; branch_tactic K'N'
Ltac\ unfold\_goal\_until\_disjunction :=
   match goal with
   |\vdash \_ \lor \_ \Rightarrow idtac
   | \_ \Rightarrow progress(unfolds); unfold\_goal\_until\_disjunction
   end.
Ltac get\_term\_disjunction\_arity\ T :=
   {\tt match}\ T\ {\tt with}
   \mid \_ \lor \_ \lor \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(8)
   \_ \lor \_ \lor \_ \lor \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(7)
    \_ \lor \_ \lor \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(6)
    \_ \lor \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(5)
    \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(4)
    \_ \lor \_ \lor \_ \Rightarrow constr:(3)
    \_ \lor \_ \Rightarrow constr:(2)
    \_ \rightarrow ?T' \Rightarrow get\_term\_disjunction\_arity\ T'
    \_\Rightarrow let P:=get\_head\ T in
             let T' := \text{eval unfold } P \text{ in } T \text{ in}
             match T' with
             \mid T \Rightarrow \text{fail } 1
             | \_ \Rightarrow qet\_term\_disjunction\_arity T'
             end
   end.
Ltac get\_goal\_disjunction\_arity :=
   match goal with \vdash ?T \Rightarrow get\_term\_disjunction\_arity\ T end.
    branch N applies to a goal of the form P1 \vee ... \vee PK \vee ... \vee PN and leaves the goal PK.
It only able to unfold the head definition (if there is one), but for more complex unfolding
one should use the tactic branch K of N.
Tactic Notation "branch" constr(K) :=
   let K := nat\_from\_number K in
   unfold_goal_until_disjunction;
   let N := get\_goal\_disjunction\_arity in
   branch\_tactic\ K\ N.
    branch K of N is similar to branch K except that the arity of the disjunction N is given
```

manually, and so this version of the tactic is able to unfold definitions. In other words, applies to a goal of the form  $P1 \vee ... \vee PK \vee ... \vee PN$  and leaves the goal PK.

```
Tactic Notation "branch" constr(K) "of" constr(N) :=
  let N := nat\_from\_number \ N in
  let K := nat\_from\_number K in
  branch\_tactic\ K\ N.
    N-ary Disjunction Deconstruction
    Underlying implementation of branches.
Ltac destructs\_disjunction\_tactic\ N\ T:=
  \mathtt{match}\ N with
    2 \Rightarrow \text{destruct } T \text{ as } [? \mid ?]
   | 3 \Rightarrow \text{destruct } T \text{ as } [? | [? | ?]]
    \mid 4 \Rightarrow \text{destruct } T \text{ as } [? \mid [? \mid [? \mid ?]]]
    | 5 \Rightarrow \text{destruct } T \text{ as } [? \mid [? \mid [? \mid [? \mid ?]]]]
    end.
    branches T allows destructing a term T which is a N-ary disjunction. It is equivalent to
destruct T as [H1 \mid ... \mid HN], and produces N subgoals corresponding to the N possible
cases.
Tactic Notation "branches" constr(T) :=
  let TT := type \ of \ T in
  let N := qet\_term\_disjunction\_arity\ TT in
  destructs\_disjunction\_tactic\ N\ T.
    branches N T is the same as branches T except that the arity is forced to N. This version
is useful to unfold definitions on the fly.
Tactic Notation "branches" constr(N) constr(T) :=
  let N := nat\_from\_number \ N in
  destructs\_disjunction\_tactic\ N\ T.
    N-ary Existentials
Ltac get\_term\_existential\_arity\ T:=
  match T with
    \exists x1 \ x2 \ x3 \ x4 \ x5 \ x6 \ x7 \ x8, \bot \Rightarrow constr:(8)
    \exists x1 \ x2 \ x3 \ x4 \ x5 \ x6 \ x7, \_ \Rightarrow constr:(7)
    \exists x1 \ x2 \ x3 \ x4 \ x5 \ x6, \bot \Rightarrow constr:(6)
    \exists x1 \ x2 \ x3 \ x4 \ x5, \bot \Rightarrow constr:(5)
    \exists x1 \ x2 \ x3 \ x4, \ \Rightarrow constr:(4)
    \exists x1 \ x2 \ x3, \ \bot \Rightarrow constr:(3)
    \exists x1 \ x2, \_ \Rightarrow constr:(2)
    \exists x1, \_ \Rightarrow constr:(1)
    \_ \rightarrow ?T' \Rightarrow get\_term\_existential\_arity\ T'
```

 $\_\Rightarrow \mathtt{let}\; P := \mathit{get\_head}\; T \; \mathtt{in}$ 

```
let T' := \text{eval unfold } P \text{ in } T \text{ in}
           {\tt match}\ T' with
            \mid T \Rightarrow \texttt{fail} \ 1
            | \_ \Rightarrow get\_term\_existential\_arity T'
            end
  end.
Ltac qet\_qoal\_existential\_arity :=
  match goal with \vdash ?T \Rightarrow get\_term\_existential\_arity\ T end.
    \exists T1 \dots TN is a shorthand for \exists T1; \dots; \exists TN. It is intended to prove goals of the
form exist X1 .. XN, P. If an argument provided is __ (double underscore), then an evar
is introduced. \exists T1 \dots TN ___ is equivalent to \exists T1 \dots TN __ _ with as many __ as
possible.
Tactic Notation "exists_original" constr(T1) :=
  \exists T1.
Tactic Notation "exists" constr(T1) :=
  match T1 with
   | ltac\_wild \Rightarrow esplit
   ltac\_wilds \Rightarrow \texttt{repeat}\ esplit
  | \_ \Rightarrow \exists T1
  end.
Tactic Notation "exists" constr(T1) constr(T2) :=
  \exists T1; \exists T2.
Tactic Notation "exists" constr(T1) constr(T2) constr(T3) :=
  \exists T1; \exists T2; \exists T3.
Tactic Notation "exists" constr(T1) constr(T2) constr(T3) constr(T4) :=
  \exists T1; \exists T2; \exists T3; \exists T4.
Tactic Notation "exists" constr(T1) constr(T2) constr(T3) constr(T4)
 constr(T5) :=
  \exists T1; \exists T2; \exists T3; \exists T4; \exists T5.
Tactic Notation "exists" constr(T1) constr(T2) constr(T3) constr(T4)
 constr(T5) constr(T6) :=

     match N with
     | 0 \Rightarrow idtac
     \mid S ? N' \Rightarrow esplit; aux N'
     end in
  let N := nat\_from\_number \ N in aux \ N.
Tactic Notation "exists___" :=
  let N := qet\_goal\_existential\_arity in
```

## 5.12 Tactics to prove typeclass instances

typeclass is an automation tactic specialized for finding typeclass instances.

```
Tactic Notation "typeclass" := let go = := eauto with typeclass\_instances in solve [ go \ tt | constructor; go \ tt ].

solve\_typeclass is a simpler version of typeclass, to use in hint tactics for resolving instances

Tactic Notation "solve\_typeclass" := solve [ eauto with typeclass\_instances ].
```

#### 5.13 Tactics to invoke automation

#### 5.13.1 jauto, a new automation tactics

jauto is better at intuition eauto because it can open existentials from the context. In the same time, jauto can be faster than intuition eauto because it does not destruct disjunctions from the context. The strategy of jauto can be summarized as follows:

- open all the existentials and conjunctions from the context
- call esplit and split on the existentials and conjunctions in the goal
- call eauto.

```
Ltac jauto\_set\_hyps :=
  repeat match goal with H: ?T \vdash \_ \Rightarrow
     {\tt match}\ T\ {\tt with}
     | \_ \land \_ \Rightarrow \text{destruct } H
      \mid \exists \ a, \ \_ \Rightarrow \texttt{destruct} \ H
     | \_ \Rightarrow generalizes H

iauto is a shorthand for intuition eauto
Tactic Notation "iauto" := try solve [intuition eauto].
```

#### 5.13.2 Definitions of automation tactics

The two following tactics defined the default behaviour of "light automation" and "strong automation". These tactics may be redefined at any time using the syntax Ltac .. ::= ...  $auto\_tilde$  is the tactic which will be called each time a symbol  $\neg$  is used after a tactic.

```
Ltac auto\_tilde\_default := auto.

Ltac auto\_tilde := auto\_tilde\_default.

auto\_star is the tactic which will be called each time a symbol \times is used after a tactic.

Ltac auto\_star\_default := try solve [ auto | eauto | intuition eauto ].

Ltac auto\_star := auto\_star\_default.
```

auto $\neg$  is a notation for tactic *auto\_tilde*. It may be followed by lemmas (or proofs terms) which auto will be able to use for solving the goal.

```
Tactic Notation "auto" "^{\sim}" := auto\_tilde.
Tactic Notation "auto" "^{\sim}" constr(E1) :=
```

```
lets: E1; auto_tilde.
Tactic Notation "auto" "^{-}" constr(E1) constr(E2) :=
  lets: E1; lets: E2; auto_tilde.
Tactic Notation "auto" "^{\sim}" constr(E1) constr(E2) constr(E3) :=
  lets: E1; lets: E2; lets: E3; auto_tilde.
   auto × is a notation for tactic auto_star. It may be followed by lemmas (or proofs terms)
which auto will be able to use for solving the goal.
Tactic Notation "auto" "*" :=
  auto\_star.
Tactic Notation "auto" "*" constr(E1) :=
  lets: E1; auto_star.
Tactic Notation "auto" "*" constr(E1) constr(E2) :=

Tactic Notation "auto_false" "*" :=
   auto\_false\_base ltac:(fun tt \Rightarrow auto^*).
```

#### 5.13.3 Definitions for parsing compatibility

```
Tactic Notation "f_equal" :=
  f_equal.
Tactic Notation "constructor" :=
  constructor.
Tactic Notation "simple" :=
  simpl.
```

#### 5.13.4 Parsing for light automation

Any tactic followed by the symbol  $\neg$  will have  $auto\_tilde$  called on all of its subgoals. Three exceptions:

- cuts and asserts only call auto on their first subgoal,
- apply relies on *sapply* rather than apply,
- tryfalse¬ is defined as tryfalse by auto\_tilde.

Some builtin tactics are not defined using tactic notations and thus cannot be extended, e.g. simpl and unfold. For these, notation such as simpl¬ will not be available.

## 5.14 Tactics to sort out the proof context

#### 5.14.1 Hiding hypotheses

```
Definition ltac\_something\ (P:Type)\ (e:P) := e.
Notation "'Something'" :=
  (@ltac\_something \_ \_).
Lemma ltac\_something\_eq : \forall (e:Type),
  e = (@ltac\_something \_ e).
Proof. auto. Qed.
Lemma ltac\_something\_hide : \forall (e:Type),
  e \rightarrow (@ltac\_something \_ e).
Proof. auto. Qed.
Lemma ltac\_something\_show : \forall (e:Type),
  (@ltac\_something \_ e) \rightarrow e.
Proof. auto. Qed.
   hide_{-}def \times and show_{-}def \times can be used to hide/show the body of the definition x.
Tactic Notation "hide_def" hyp(x) :=
  let x' := constr:(x) in
  let T := \text{eval unfold } x \text{ in } x' \text{ in }
  change T with (@ltac\_something\_T) in x.
Tactic Notation "show_def" hyp(x) :=
  let x' := constr:(x) in
  let U := \text{eval unfold } x \text{ in } x' \text{ in }
  match U with @ltac\_something \_?T \Rightarrow
     change U with T in x end.
   show_def unfolds Something in the goal
Tactic Notation "show_def" :=
  unfold ltac\_something.
Tactic Notation "show_def" "in" "*" :=
  unfold ltac_something in *.
   hide_defs and show_defs applies to all definitions
Tactic Notation "hide_defs" :=
  repeat match goal with H := ?T \vdash \_ \Rightarrow
```

```
{\tt match}\ T\ {\tt with}
      @ltac\_something \_ \_ \Rightarrow fail 1
     | \_ \Rightarrow change T with (@ltac_something \_ T) in H
     end
  end.
Tactic Notation "show_defs" :=
  repeat match goal with H := (@ltac\_somethinq\_?T) \vdash \_ \Rightarrow
     change (@ltac\_something \_ T) with T in H end.
   hide_hyp\ H replaces the type of H with the notation Something and show_hyp\ H reveals
the type of the hypothesis. Note that the hidden type of H remains convertible the real type
of H.
Tactic Notation "show_hyp" hyp(H) :=
  apply ltac\_something\_show in H.
Tactic Notation "hide-hyp" hyp(H) :=
  apply ltac\_something\_hide in H.
   hide_hyps and show_hyps can be used to hide/show all hypotheses of type Prop.
Tactic Notation "show_hyps" :=
  repeat match goal with
     H: @ltac\_something \_ \_ \vdash \_ \Rightarrow show\_hyp \ H \ end.
Tactic Notation "hide_hyps" :=
  repeat match goal with H: ?T \vdash \bot \Rightarrow
    match type of T with
    | \text{Prop} \Rightarrow
       {\tt match}\ T\ {\tt with}
        @ltac\_something \_ \_ \Rightarrow fail 2
       | \_ \Rightarrow hide\_hyp H
       end
    |  \Rightarrow fail 1
    end
  end.
   hide H and show H automatically select between hide_hyp or hide_def, and show_hyp or
show_def. Similarly hide_all and show_all apply to all.
Tactic Notation "hide" hyp(H) :=
  first [hide\_def \ H \mid hide\_hyp \ H].
Tactic Notation "show" hyp(H) :=
  first [show\_def \ H \mid show\_hyp \ H].
Tactic Notation "hide_all" :=
  hide_hyps; hide_defs.
Tactic Notation "show_all" :=
```

```
unfold ltac_something in *.
```

 $hide\_term\ E$  can be used to hide a term from the goal.  $show\_term$  or  $show\_term\ E$  can be used to reveal it.  $hide\_term\ E$  in H can be used to specify an hypothesis.

```
Tactic Notation "hide_term" \operatorname{constr}(E) := \operatorname{change} E with (@ltac\_something \_ E).

Tactic Notation "show_term" \operatorname{constr}(E) := \operatorname{change} (@ltac\_something \_ E) with E.

Tactic Notation "show_term" := \operatorname{unfold} ltac\_something.

Tactic Notation "hide_term" \operatorname{constr}(E) "in" hyp(H) := \operatorname{change} E with (@ltac\_something \_ E) in H.

Tactic Notation "show_term" \operatorname{constr}(E) "in" hyp(H) := \operatorname{change} (@ltac\_something \_ E) with E in H.

Tactic Notation "show_term" "in" hyp(H) := \operatorname{unfold} ltac\_something in H.
```

#### 5.14.2 Sorting hypotheses

sort sorts out hypotheses from the context by moving all the propositions (hypotheses of type Prop) to the bottom of the context.

```
Ltac sort\_tactic :=
try match goal with H: ?T \vdash \_ \Rightarrow
match type \ of \ T with Prop \Rightarrow
generalizes \ H; \ (try \ sort\_tactic); \ intro
end end.

Tactic Notation "sort" :=
sort\_tactic.
```

#### 5.14.3 Clearing hypotheses

clears X1 ... XN is a variation on clear which clears the variables X1..XN as well as all the hypotheses which depend on them. Contrary to clear, it never fails.

```
Tactic Notation "clears" ident(X1) :=  let rec\ doit\ \_ :=  match goal with |\ H: \mathtt{context}[X1] \vdash \_ \Rightarrow \mathtt{clear}\ H; \ \mathtt{try}\ (doit\ tt)  |\ \_ \Rightarrow \mathtt{clear}\ X1  end in doit\ tt.
Tactic Notation "clears" ident(X1)\ ident(X2) :=  clears\ X1;\ clears\ X2.
Tactic Notation "clears" ident(X1)\ ident(X2)\ ident(X3) :=
```

```
clears X1; clears X2; clear X3.
Tactic Notation "clears" ident(X1) \ ident(X2) \ ident(X3) \ ident(X4) :=
  clears X1; clears X2; clear X3; clear X4.
Tactic Notation "clears" ident(X1) ident(X2) ident(X3) ident(X4)
 ident(X5) :=
  clears X1; clear X2; clear X3; clear X4; clear X5.
Tactic Notation "clears" ident(X1) ident(X2) ident(X3) ident(X4)
 ident(X5) \ ident(X6) :=
  clears X1; clear X2; clear X3; clear X4; clear X5; clear X6.
   clears (without any argument) clears all the unused variables from the context. In other
words, it removes any variable which is not a proposition (i.e. not of type Prop) and which
does not appear in another hypothesis nor in the goal.
Ltac clears\_tactic :=
  match goal with H: ?T \vdash \_ \Rightarrow
  match type of T with
  | \text{ Prop} \Rightarrow generalizes \ H; (try \ clears\_tactic); intro
   ?TT \Rightarrow clear H; (try clears\_tactic)
  |?TT \Rightarrow generalizes H; (try clears_tactic); intro
  end end.
Tactic Notation "clears" :=
  clears\_tactic.
   clears_all clears all the hypotheses from the context that can be cleared. It leaves only
the hypotheses that are mentioned in the goal.
Tactic Notation "clears_all" :=
  repeat match goal with H: \_ \vdash \_ \Rightarrow \text{clear } H \text{ end.}
   clears_last clears the last hypothesis in the context. clears_last N clears the last N
hypotheses in the context.
Tactic Notation "clears_last" :=
  match goal with H: ?T \vdash \bot \Rightarrow \text{clear } H \text{ end.}
Ltac clears\_last\_base\ N :=
  match nat\_from\_number\ N with
  \mid 0 \Rightarrow \text{idtac}
```

 $|S| ?p \Rightarrow clears\_last; clears\_last\_base p$ 

Tactic Notation "clears\_last" constr(N) :=

end.

 $clears\_last\_base\ N.$ 

## 5.15 Tactics for development purposes

### 5.15.1 Skipping subgoals

The *skip* tactic can be used at any time to admit the current goal. Using *skip* is much more efficient than using the *Focus* top-level command to reach a particular subgoal.

There are two possible implementations of *skip*. The first one relies on the use of an existential variable. The second one relies on an axiom of type **False**. Remark that the builtin tactic **admit** is not applicable if the current goal contains uninstantiated variables.

The advantage of the first technique is that a proof using *skip* must end with *Admitted*, since Qed will be rejected with the message "*uninstantiated existential variables*". It is thereafter clear that the development is incomplete.

The advantage of the second technique is exactly the converse: one may conclude the proof using Qed, and thus one saves the pain from renaming Qed into Admitted and vice-versa all the time. Note however, that it is still necessary to instantiate all the existential variables introduced by other tactics in order for Qed to be accepted.

The two implementation are provided, so that you can select the one that suits you best. By default skip' uses the first implementation, and skip uses the second implementation.

```
Ltac skip\_with\_existential :=
match goal with \vdash ?G \Rightarrow
let H := fresh in evar(H:G); eexact H end.
Variable skip\_axiom : False.
Ltac skip\_with\_axiom :=
elimtype \ False; apply \ skip\_axiom.
Tactic Notation "skip" :=
skip\_with\_axiom.
Tactic Notation "skip'" :=
skip\_with\_existential.
```

 $skip\ H$ : T adds an assumption named H of type T to the current context, blindly assuming that it is true. skip: T and  $skip\ H\_asserts$ : T and  $skip\_asserts$ : T are other possible syntax. Note that H may be an intro pattern. The syntax  $skip\ H1$  .. HN: T can be used when T is a conjunction of N items.

```
Tactic Notation "skip" simple\_intropattern(I) ":" constr(T) := asserts\ I:\ T;\ [\ skip\ ]\ ].
Tactic Notation "skip" ":" constr(T) := let\ H := fresh\ in\ skip\ H:\ T.
Tactic Notation "skip" simple\_intropattern(I1) simple\_intropattern(I2) ":" constr(T) := skip\ [I1\ I2]:\ T.
Tactic Notation "skip" simple\_intropattern(I1) simple\_intropattern(I2) simple\_intropattern(I3) ":" constr(T) := simple\_intropattern(I2) simple\_intropattern(I3) ":" constr(T) := simple\_intropattern(I3) ":"
```

```
skip [11 [12 13]]: T.
Tactic Notation "skip" simple\_intropattern(I1)
 simple\_intropattern(I2) \ simple\_intropattern(I3)
 simple\_intropattern(I_4) ":" constr(T) :=
  skip [11 [12 [13 14]]]: T.
Tactic Notation "skip" simple\_intropattern(I1)
 simple\_intropattern(I2) simple\_intropattern(I3)
 simple\_intropattern(I_4) \ simple\_intropattern(I_5) \ ":" \ constr(T) :=
  skip [11 [12 [13 [14 15]]]]: T.
Tactic Notation "skip" simple\_intropattern(I1)
 simple\_intropattern(I2) \ simple\_intropattern(I3)
 simple\_intropattern(I_4) simple\_intropattern(I_5)
 simple\_intropattern(I6) ":" constr(T) :=
  skip [I1 [I2 [I3 [I4 [I5 I6]]]]]: T.
Tactic Notation "skip_asserts" simple_intropattern(I) ":" constr(T) :=
  skip I: T.
Tactic Notation "skip_asserts" ":" constr(T) :=
  skip: T.
   skip\_cuts \ T simply replaces the current goal with T.
Tactic Notation "skip_cuts" constr(T) :=
  cuts: T; | skip | |.
   skip_qoal H applies to any goal. It simply assumes the current goal to be true. The
assumption is named "H". It is useful to set up proof by induction or coinduction. Syntax
skip_goal is also accepted.
Tactic Notation "skip\_goal" ident(H) :=
  match goal with \vdash ?G \Rightarrow skip \ H : G end.
Tactic Notation "skip_goal" :=
  let IH := fresh "IH" in skip\_goal IH.
   skip\_rewrite\ T can be applied when T is an equality. It blindly assumes this equality to
be true, and rewrite it in the goal.
Tactic Notation "skip_rewrite" constr(T) :=
  let M := fresh in skip\_asserts M: T; rewrite M; clear M.
   skip\_rewrite\ T in H is similar as rewrite\_skip, except that it rewrites in hypothesis H.
Tactic Notation "skip_rewrite" constr(T) "in" hyp(H) :=
  let M := fresh in skip\_asserts \ M : \ T; rewrite M in H; clear M.
   skip_rewrites_all T is similar as rewrite_skip, except that it rewrites everywhere (goal
and all hypotheses).
Tactic Notation "skip_rewrite_all" constr(T) :=
  let M := fresh in skip\_asserts M: T; rewrite\_all M; clear M.
```

 $skip\_induction\ E$  applies to any goal. It simply assumes the current goal to be true (the assumption is named "IH" by default), and call destruct E instead of induction E. It is useful to try and set up a proof by induction first, and fix the applications of the induction hypotheses during a second pass on the proof.

```
Tactic Notation "skip_induction" constr(E) := let IH := fresh "IH" in skip\_goal IH; destruct E.

Tactic Notation "skip_induction" constr(E) "as" simple\_intropattern(I) := let IH := fresh "IH" in skip\_goal IH; destruct E as I.
```

# 5.16 Compatibility with standard library

The module Program contains definitions that conflict with the current module. If you import Program, either directly or indirectly (e.g. through *Setoid* or ZArith), you will need to import the compability definitions through the top-level command: Require Import *LibTacticsCompatibility*.

```
Module LibTacticsCompatibility.
  Tactic Notation "apply" "*" constr(H) :=
        sapply H; auto_star.
  Tactic Notation "subst" "*" :=
        subst; auto_star.
End LibTacticsCompatibility.
Open Scope nat_scope.
```

# Chapter 6

# Library Norm

## 6.1 Norm: Normalization of STLC

Require Import Stlc.

(This chapter is optional.)

In this chapter, we consider another fundamental theoretical property of the simply typed lambda-calculus: the fact that the evaluation of a well-typed program is guaranteed to halt in a finite number of steps—i.e., every well-typed term is *normalizable*.

Unlike the type-safety properties we have considered so far, the normalization property does not extend to full-blown programming languages, because these languages nearly always extend the simply typed lambda-calculus with constructs, such as general recursion (as we discussed in the MoreStlc chapter) or recursive types, that can be used to write non-terminating programs. However, the issue of normalization reappears at the level of types when we consider the metatheory of polymorphic versions of the lambda calculus such as F\_omega: in this system, the language of types effectively contains a copy of the simply typed lambda-calculus, and the termination of the typechecking algorithm will hinge on the fact that a "normalization" operation on type expressions is guaranteed to terminate.

Another reason for studying normalization proofs is that they are some of the most beautiful—and mind-blowing—mathematics to be found in the type theory literature, often (as here) involving the fundamental proof technique of *logical relations*.

The calculus we shall consider here is the simply typed lambda-calculus over a single base type **bool** and with pairs. We'll give full details of the development for the basic lambda-calculus terms treating **bool** as an uninterpreted base type, and leave the extension to the boolean operators and pairs to the reader. Even for the base calculus, normalization is not entirely trivial to prove, since each reduction of a term can duplicate redexes in subterms.

**Exercise: 1 star** Where do we fail if we attempt to prove normalization by a straightforward induction on the size of a well-typed term?

# 6.2 Language

We begin by repeating the relevant language definition, which is similar to those in the MoreStlc chapter, and supporting results including type preservation and step determinism. (We won't need progress.) You may just wish to skip down to the Normalization section...

#### Syntax and Operational Semantics

```
Inductive ty : Type :=
    TBool: ty
     TArrow : ty \rightarrow ty \rightarrow ty
    TProd : ty \rightarrow ty \rightarrow ty
Tactic Notation "T_cases" tactic(first) ident(c) :=
   first;

## 6.3 Normalization

Now for the actual normalization proof.

Our goal is to prove that every well-typed term evaluates to a normal form. In fact, it turns out to be convenient to prove something slightly stronger, namely that every well-typed term evaluates to a *value*. This follows from the weaker property anyway via the Progress lemma (why?) but otherwise we don't need Progress, and we didn't bother re-proving it above.

Here's the key definition:

```
Definition halts (t:\mathbf{tm}): \mathsf{Prop} := \exists \ t', \ t ==>* \ t' \land \mathsf{value} \ t'. A trivial fact: Lemma value_halts : \forall \ v, \mathsf{value} \ v \to \mathsf{halts} \ v. Proof. intros v \ H. unfold halts.
```

```
∃ v. split.

apply multi_refl.

assumption.

Qed.
```

The key issue in the normalization proof (as in many proofs by induction) is finding a strong enough induction hypothesis. To this end, we begin by defining, for each type T, a set  $R_{-}T$  of closed terms of type T. We will specify these sets using a relation  $\mathbf{R}$  and write  $\mathbf{R}$  T t when t is in  $R_{-}T$ . (The sets  $R_{-}T$  are sometimes called saturated sets or reducibility candidates.)

Here is the definition of **R** for the base language:

- **R bool** t iff t is a closed term of type **bool** and t halts in a value
- $R(T1 \to T2)$  t iff t is a closed term of type  $T1 \to T2$  and t halts in a value and for any term s such that R(T1) s, we have R(T2) (t s).

This definition gives us the strengthened induction hypothesis that we need. Our primary goal is to show that all *programs*—i.e., all closed terms of base type—halt. But closed terms of base type can contain subterms of functional type, so we need to know something about these as well. Moreover, it is not enough to know that these subterms halt, because the application of a normalized function to a normalized argument involves a substitution, which may enable more evaluation steps. So we need a stronger condition for terms of functional type: not only should they halt themselves, but, when applied to halting arguments, they should yield halting results.

The form of R is characteristic of the *logical relations* proof technique. (Since we are just dealing with unary relations here, we could perhaps more properly say *logical predicates*.) If we want to prove some property P of all closed terms of type A, we proceed by proving, by induction on types, that all terms of type A possess property P, all terms of type  $A \rightarrow A$  preserve property P, all terms of type  $A \rightarrow A$  preserve the property of preserving property P, and so on. We do this by defining a family of predicates, indexed by types. For the base type A, the predicate is just P. For functional types, it says that the function should map values satisfying the predicate at the input type to values satisfying the predicate at the output type.

When we come to formalize the definition of R in Coq, we hit a problem. The most obvious formulation would be as a parameterized Inductive proposition like this:

Inductive  $R: ty -> tm -> Prop := | R_bool : forall b t, has_type empty t TBool -> halts t -> R TBool t | R_arrow : forall T1 T2 t, has_type empty t (TArrow T1 T2) -> halts t -> (forall s, R T1 s -> R T2 (tapp t s)) -> R (TArrow T1 T2) t.$ 

Unfortunately, Coq rejects this definition because it violates the *strict positivity require*ment for inductive definitions, which says that the type being defined must not occur to the left of an arrow in the type of a constructor argument. Here, it is the third argument to  $R\_arrow$ , namely ( $\forall$  s, R T1 s  $\rightarrow$  R TS (tapp t s)), and specifically the R T1 s part, that violates this rule. (The outermost arrows separating the constructor arguments don't count when applying this rule; otherwise we could never have genuinely inductive predicates at all!) The reason for the rule is that types defined with non-positive recursion can be used to build non-terminating functions, which as we know would be a disaster for Coq's logical soundness. Even though the relation we want in this case might be perfectly innocent, Coq still rejects it because it fails the positivity test.

Fortunately, it turns out that we can define R using a Fixpoint:

```
Fixpoint R (T:\mathbf{ty}) (t:\mathbf{tm}) {struct T} : Prop := \mathbf{has\_type} empty t T \land halts t \land (match T with | TBool \Rightarrow True | TArrow T1 T2 \Rightarrow (\forall s, R T1 s \rightarrow R T2 (tapp t s)) | TProd T1 T2 \Rightarrow False end).
```

As immediate consequences of this definition, we have that every element of every set  $R_{-}T$  halts in a value and is closed with type t:

```
Lemma R_halts : \forall { T} {t}, R T t \rightarrow halts t. Proof.
```

intros. destruct T; unfold R in H; inversion H; inversion H1; assumption. Qed.

```
Lemma R_typable_empty : \forall { T} { t}, R T t \rightarrow has_type empty t T. Proof.
```

intros. destruct T; unfold R in H; inversion H; inversion H1; assumption. Qed.

Now we proceed to show the main result, which is that every well-typed term of type T is an element of  $R_{-}T$ . Together with  $R_{-}$ halts, that will show that every well-typed term halts in a value.

## 6.3.1 Membership in $R_{-}T$ is invariant under evaluation

We start with a preliminary lemma that shows a kind of strong preservation property, namely that membership in  $R_-T$  is *invariant* under evaluation. We will need this property in both directions, i.e. both to show that a term in  $R_-T$  stays in  $R_-T$  when it takes a forward step, and to show that any term that ends up in  $R_-T$  after a step must have been in  $R_-T$  to begin with.

First of all, an easy preliminary lemma. Note that in the forward direction the proof depends on the fact that our language is determinstic. This lemma might still be true for non-deterministic languages, but the proof would be harder!

```
Lemma step_preserves_halting : \forall \ t \ t', \ (t ==> t') \rightarrow (\text{halts } t \leftrightarrow \text{halts } t'). Proof.
```

intros t t ST. unfold halts.

```
split. Case \text{ "->".} intros [t" [STM V]]. inversion STM; \text{ subst.} apply \text{ ex_falso_quodlibet. apply value_normal in } V. \text{ unfold normal_form in } V. \text{ apply } V. \exists t'. \text{ auto.} \text{rewrite } (step\_deterministic \_\_\_ST \ H). \exists t". \text{ split; assumption.} Case \text{ "<-".} \text{intros } [t'0 \ [STM \ V]]. \exists \ t'0. \text{ split; eauto.} \text{Qed.}
```

Now the main lemma, which comes in two parts, one for each direction. Each proceeds by induction on the structure of the type T. In fact, this is where we make fundamental use of the finiteness of types.

One requirement for staying in  $R_{-}T$  is to stay in type T. In the forward direction, we get this from ordinary type Preservation.

```
Lemma step_preserves_R : \forall T \ t \ t', (t ==> t') \rightarrow R \ T \ t \rightarrow R \ T \ t'.
Proof.
 induction T; intros t t' E Rt; unfold R; fold R; unfold R in Rt; fold R in Rt;
                  destruct Rt as [typable\_empty\_t [halts\_t RRt]].
  split. eapply preservation; eauto.
  split. apply (step_preserves_halting _ _ E); eauto.
  auto.
  split. eapply preservation; eauto.
  split. apply (step\_preserves\_halting \_ \_ E); eauto.
  intros.
  eapply IHT2.
  apply ST_App1. apply E.
  apply RRt; auto.
   Admitted.
   The generalization to multiple steps is trivial:
Lemma multistep_preserves_R : \forall T t t',
  (t ==> * t') \rightarrow R T t \rightarrow R T t'.
Proof.
  intros T t t ' STM; induction STM; intros.
  assumption.
```

In the reverse direction, we must add the fact that t has type T before stepping as an additional hypothesis.

apply IHSTM. eapply  $step\_preserves\_R$ . apply H. assumption.

```
Lemma step_preserves_R' : \forall T t t',
```

Qed.

```
\begin{array}{l} \textbf{has\_type} \text{ empty } t \ T \rightarrow (t ==> t') \rightarrow \mathsf{R} \ T \ t' \rightarrow \mathsf{R} \ T \ t. \\ \textbf{Proof.} \\ Admitted. \\ \textbf{Lemma multistep\_preserves\_R'} : \forall \ T \ t \ t', \\ \textbf{has\_type} \text{ empty } t \ T \rightarrow (t ==>* t') \rightarrow \mathsf{R} \ T \ t' \rightarrow \mathsf{R} \ T \ t. \\ \textbf{Proof.} \\ \text{intros } T \ t \ ' \ HT \ STM. \\ \text{induction } STM; \text{ intros.} \\ \text{assumption.} \\ \text{eapply } step\_preserves\_R'. \text{ assumption. apply } H. \text{ apply } IHSTM. \\ \text{eapply preservation; eauto. auto.} \\ \textbf{Qed.} \\ \end{array}
```

### 6.3.2 Closed instances of terms of type T belong to $R_{-}T$

Now we proceed to show that every term of type T belongs to  $R_-T$ . Here, the induction will be on typing derivations (it would be surprising to see a proof about well-typed terms that did not somewhere involve induction on typing derivations!). The only technical difficulty here is in dealing with the abstraction case. Since we are arguing by induction, the demonstration that a term tabs  $\times$  T1 t2 belongs to  $R_-(T1 \rightarrow T2)$  should involve applying the induction hypothesis to show that t2 belongs to  $R_-(T2)$ . But  $R_-(T2)$  is defined to be a set of closed terms, while t2 may contain  $\times$  free, so this does not make sense.

This problem is resolved by using a standard trick to suitably generalize the induction hypothesis: instead of proving a statement involving a closed term, we generalize it to cover all closed instances of an open term t. Informally, the statement of the lemma will look like this:

If  $x1:T1,...xn:Tn \vdash t: T \text{ and } v1,...,vn \text{ are values such that } \mathbf{R} \ T1 \ v1, \ \mathbf{R} \ T2 \ v2, ..., \ \mathbf{R} \ Tn \ vn, \text{ then } \mathbf{R} \ T \ ([x1:=v1][x2:=v2]...[xn:=vn]t).$ 

The proof will proceed by induction on the typing derivation  $x1:T1,...xn:Tn \vdash t:T$ ; the most interesting case will be the one for abstraction.

#### Multisubstitutions, multi-extensions, and instantiations

However, before we can proceed to formalize the statement and proof of the lemma, we'll need to build some (rather tedious) machinery to deal with the fact that we are performing multiple substitutions on term t and multiple extensions of the typing context. In particular, we must be precise about the order in which the substitutions occur and how they act on each other. Often these details are simply elided in informal paper proofs, but of course Coq won't let us do that. Since here we are substituting closed terms, we don't need to worry about how one substitution might affect the term put in place by another. But we still do need to worry about the order of substitutions, because it is quite possible for the same identifier to appear multiple times among the x1,...xn with different associated vi and Ti.

To make everything precise, we will assume that environments are extended from left to right, and multiple substitutions are performed from right to left. To see that this is consistent, suppose we have an environment written as ...,y:bool,...,y:nat,... and a corresponding term substitution written as ...[ $y:=(tbool\ true)]...[y:=(tnat\ 3)]...t$ . Since environments are extended from left to right, the binding y:nat hides the binding y:bool; since substitutions are performed right to left, we do the substitution  $y:=(tnat\ 3)$  first, so that the substitution  $y:=(tbool\ true)$  has no effect. Substitution thus correctly preserves the type of the term.

With these points in mind, the following definitions should make sense.

A multisubstitution is the result of applying a list of substitutions, which we call an environment.

```
Definition env := list (id \times tm).

Fixpoint msubst (ss:env) (t:tm) {struct ss} : tm := match ss with | nil \Rightarrow t | ((x,s)::ss') \Rightarrow msubst ss' ([x:=s]t)
```

We need similar machinery to talk about repeated extension of a typing context using a list of (identifier, type) pairs, which we call a *type assignment*.

```
Definition tass := list (id \times ty).

Fixpoint mextend (Gamma : context) (xts : tass) := match xts with | \ nil \Rightarrow Gamma \ | \ ((x,v)::xts') \Rightarrow \text{ extend (mextend } Gamma \ xts') \ x \ v \ \text{end.}
```

We will need some simple operations that work uniformly on environments and type assigments

```
Fixpoint lookup \{X: \mathsf{Set}\}\ (k: \mathsf{id})\ (l: \mathsf{list}\ (\mathsf{id} \times X))\ \{\mathsf{struct}\ l\}: \mathsf{option}\ X := \mathsf{match}\ l\ \mathsf{with}
|\ \mathsf{nil} \Rightarrow \mathsf{None}\ |\ (j,x) :: l' \Rightarrow \\ \mathsf{if}\ \mathsf{eq\_id\_dec}\ j\ k\ \mathsf{then}\ \mathsf{Some}\ x\ \mathsf{else}\ \mathsf{lookup}\ k\ l' \\ \mathsf{end}.
Fixpoint drop \{X: \mathsf{Set}\}\ (n: \mathsf{id})\ (nxs: \mathsf{list}\ (\mathsf{id} \times X))\ \{\mathsf{struct}\ nxs\}: \mathsf{list}\ (\mathsf{id} \times X) := \\ \mathsf{match}\ nxs\ \mathsf{with} \\ |\ \mathsf{nil} \Rightarrow \mathsf{nil}\ |\ ((n',x)::nxs') \Rightarrow \mathsf{if}\ \mathsf{eq\_id\_dec}\ n'\ n\ \mathsf{then}\ \mathsf{drop}\ n\ nxs'\ \mathsf{else}\ (n',x):: (\mathsf{drop}\ n\ nxs') \\ \mathsf{end}.
```

An instantiation combines a type assignment and a value environment with the same domains, where corresponding elements are in R

```
Inductive instantiation : tass \rightarrow env \rightarrow Prop :=
```

```
| V_nil : instantiation nil nil | V_cons : \forall x \ T \ v \ c \ e, value v \to \mathsf{R} \ T \ v \to \mathsf{instantiation} \ c \ e \to \mathsf{instantiation} \ ((x, T) :: c) \ ((x, v) :: e).
```

We now proceed to prove various properties of these definitions.

#### More Substitution Facts

```
First we need some additional lemmas on (ordinary) substitution.
```

```
Lemma vacuous_substitution : \forall t x,
      \neg appears_free_in x t \rightarrow
      \forall t', [x := t'] t = t.
Proof with eauto.
   Admitted.
Lemma subst_closed: \forall t,
      closed t \rightarrow
      \forall x \ t', [x := t'] t = t.
Proof.
  intros. apply vacuous_substitution. apply H. Qed.
Lemma subst_not_afi : \forall t x v, closed v \rightarrow \neg appears_free_in x ([x:=v]t).
Proof with eauto.
                       unfold closed, not.
  t\_cases (induction t) Case; intros x \ v \ P \ A; simpl in A.
     Case "tvar".
      destruct (eq_id_dec x i)...
        inversion A; subst. auto.
     Case "tapp".
      inversion A; subst...
     Case "tabs".
      destruct (eq_id_dec x i)...
        inversion A; subst...
        inversion A; subst...
     Case "tpair".
      inversion A; subst...
     Case "tfst".
      inversion A; subst...
     Case "tsnd".
      inversion A; subst...
     Case "ttrue".
      inversion A.
     Case "tfalse".
      inversion A.
     Case "tif".
      inversion A; subst...
```

```
Qed.
Lemma duplicate_subst : \forall t' x t v,
  closed v \rightarrow [x:=t]([x:=v]t') = [x:=v]t'.
Proof.
  intros. eapply vacuous_substitution. apply subst_not_afi. auto.
Lemma swap_subst : \forall t \ x \ x1 \ v \ v1, \ x \neq x1 \rightarrow \mathsf{closed} \ v \rightarrow \mathsf{closed} \ v1 \rightarrow
                        [x1 := v1]([x := v]t) = [x := v]([x1 := v1]t).
Proof with eauto.
 t\_cases (induction t) Case; intros; simpl.
  Case "tvar".
   destruct (eq_id_dec x i); destruct (eq_id_dec x1 i).
       subst. apply ex_falso_quodlibet...
       subst. simpl. rewrite eq_id. apply subst_closed...
       subst. simpl. rewrite eq_id. rewrite subst_closed...
       simpl. rewrite neg_id... rewrite neg_id...
   Admitted.
Properties of multi-substitutions
Lemma msubst_closed: \forall t, closed t \rightarrow \forall ss, msubst ss \ t = t.
Proof.
  induction ss.
     reflexivity.
     destruct a. simpl. rewrite subst_closed; assumption.
Qed.
    Closed environments are those that contain only closed terms.
Fixpoint closed_env (env:env) {struct env} :=
match \ env \ with
| \text{ nil} \Rightarrow \text{True} |
(x,t)::env'\Rightarrow closed\ t\wedge closed\_env\ env'
end.
   Next come a series of lemmas charcterizing how msubst of closed terms distributes over
subst and over each term form
Lemma subst_msubst: \forall \ env \ x \ v \ t, closed v \to \mathsf{closed\_env} \ env \to
  msubst env([x:=v]t) = [x:=v] (msubst (drop x env)t).
Proof.
  induction env\theta; intros.
```

auto.

destruct a. simpl.

inversion H0. fold closed\_env in H2.

```
destruct (eq_id_dec i x).
       subst. rewrite duplicate_subst; auto.
       simpl. rewrite swap_subst; eauto.
Qed.
Lemma msubst_var: \forall ss x, closed_env ss \rightarrow
   msubst ss (tvar x) =
   match lookup x ss with
   | Some t \Rightarrow t
   | None \Rightarrow tvar x
  end.
Proof.
  induction ss; intros.
    reflexivity.
    destruct a.
      simpl. destruct (eq_id_dec i x).
       apply msubst\_closed. inversion H; auto.
       apply IHss. inversion H; auto.
Qed.
Lemma msubst_abs: \forall ss x T t,
  msubst ss (tabs x \ T \ t) = tabs x \ T (msubst (drop x \ ss) t).
Proof.
  induction ss; intros.
    reflexivity.
    destruct a.
       simpl. destruct (eq_id_dec i x); simpl; auto.
Qed.
Lemma msubst_app : \forall ss \ t1 \ t2, msubst ss \ (tapp \ t1 \ t2) = tapp \ (msubst \ ss \ t1) \ (msubst \ ss \ t2).
Proof.
 induction ss; intros.
   reflexivity.
   destruct a.
     simpl. rewrite \leftarrow IHss. auto.
Qed.
```

You'll need similar functions for the other term constructors.

#### Properties of multi-extensions

We need to connect the behavior of type assignments with that of their corresponding contexts.

```
Lemma mextend_lookup : \forall (c : tass) (x:id), lookup x c = (mextend empty c) x. Proof.
```

```
induction c; intros.
    auto.
    destruct a. unfold lookup, mextend, extend. destruct (eq_id_dec i x); auto.
Qed.
Lemma mextend_drop : \forall (c: tass) Gamma \ x \ x',
        mextend Gamma (drop x c) x' = if eq_id_dec x x' then Gamma x' else mextend
Gamma \ c \ x'.
   induction c; intros.
       destruct (eq_id_dec x x'); auto.
       destruct a. simpl.
       destruct (eq_id_dec i x).
          subst. rewrite IHc.
              destruct (eq_id_dec x x'). auto. unfold extend. rewrite neq_id; auto.
          simpl. unfold extend. destruct (eq_id_dec i x').
              subst.
                  destruct (eq_id_dec x x').
                     subst. exfalso. auto.
                     auto.
             auto.
Qed.
Properties of Instantiations
These are strightforward.
Lemma instantiation_domains_match: \forall \{c\} \{e\},\
  instantiation c \in A  \{x\} \{T\}, lookup x \in Some T \to \exists t, lookup x \in Some t.
Proof.
  intros c \in V. induction V; intros x\theta \in C.
    solve by inversion .
    simpl in *.
    destruct (eq_id_dec x x\theta); eauto.
Qed.
Lemma instantiation_env_closed : \forall c e, instantiation c e \rightarrow \text{closed\_env } e.
Proof.
  intros c \in V; induction V; intros.
    econstructor.
    unfold closed_env. fold closed_env.
    split. eapply typable_empty__closed. eapply R_typable_empty. eauto.
         auto.
Qed.
Lemma instantiation_R : \forall c e, instantiation c e \rightarrow
                            \forall x \ t \ T, lookup x \ c = Some T \rightarrow
```

```
\label{eq:lookup} \begin{aligned} & \operatorname{lookup} \ x \ e = \operatorname{Some} \ t \to \operatorname{R} \ T \ t. \end{aligned} Proof.  & \operatorname{intros} \ c \ e \ V. \ \operatorname{induction} \ V; \ \operatorname{intros} \ x' \ t' \ T' \ G \ E. \\ & \operatorname{solve} \ \operatorname{by} \ \operatorname{inversion}. \\ & \operatorname{unfold} \ \operatorname{lookup} \ \operatorname{in} \ ^*. \ \operatorname{destruct} \ (\operatorname{eq\_id\_dec} \ x \ x'). \\ & \operatorname{inversion} \ G; \ \operatorname{inversion} \ E; \ \operatorname{subst.} \ \operatorname{auto}. \\ & \operatorname{eauto}. \end{aligned} Qed.  \begin{aligned} \operatorname{Qed}. \end{aligned} Lemma instantiation\_drop: & \forall \ c \ env, \\ & \operatorname{instantiation} \ c \ env \to \forall \ x, \ \operatorname{instantiation} \ (\operatorname{drop} \ x \ c) \ (\operatorname{drop} \ x \ env). \end{aligned} Proof.  \begin{aligned} & \operatorname{intros} \ c \ e \ V. \ \operatorname{induction} \ V. \\ & \operatorname{intros}. \ \operatorname{simpl.} \ \operatorname{constructor}. \\ & \operatorname{intros}. \ \operatorname{unfold} \ \operatorname{drop}. \ \operatorname{destruct} \ (\operatorname{eq\_id\_dec} \ x \ x\theta); \ \operatorname{auto}. \ \operatorname{constructor}; \ \operatorname{eauto}. \end{aligned} Qed.  \end{aligned} Qed.
```

#### Congruence lemmas on multistep

We'll need just a few of these; add them as the demand arises.

```
Lemma multistep_App2 : \forall \ v \ t \ t', value v \to (t ==>* \ t') \to (\text{tapp } v \ t) ==>* (\text{tapp } v \ t'). Proof.

intros v \ t \ t' \ V \ STM. induction STM.

apply multi_refl.

eapply multi_step.

apply ST_App2; eauto. auto.

Qed.
```

#### The R Lemma.

We finally put everything together.

The key lemma about preservation of typing under substitution can be lifted to multisubstitutions:

```
Lemma msubst_preserves_typing : \forall c e, instantiation c e \rightarrow \forall Gamma \ t \ S, has_type (mextend Gamma \ c) \ t \ S \rightarrow \text{has_type } Gamma \ (\text{msubst } e \ t) \ S.

Proof.
induction 1; intros.
simpl in H. simpl. auto.
simpl in H2. simpl.
apply IHinstantiation.
```

```
eapply substitution_preserves_typing; eauto.
    apply (R_{typable_empty} H\theta).
Qed.
   And at long last, the main lemma.
Lemma msubst_R : \forall c env t T,
  has_type (mextend empty c) t T \rightarrow instantiation c env \rightarrow R T (msubst env t).
Proof.
  intros c env0 t T HT V.
  generalize dependent env\theta.
  remember (mextend empty c) as Gamma.
  assert (\forall x, Gamma \ x = lookup \ x \ c).
    intros. rewrite HegGamma. rewrite mextend_lookup. auto.
  clear HegGamma.
  generalize dependent c.
  has_type_cases (induction HT) Case; intros.
  Case "T_Var".
   rewrite H0 in H. destruct (instantiation_domains_match V H) as [t P].
   eapply instantiation_R; eauto.
   rewrite msubst_var. rewrite P. auto. eapply instantiation_env_closed; eauto.
  Case "T_Abs".
    rewrite msubst_abs.
    assert (WT: has_type empty (tabs x T11 (msubst (drop x env\theta) t12)) (TArrow T11
T12)).
     eapply T_Abs. eapply msubst_preserves_typing. eapply instantiation_drop; eauto.
      eapply context_invariance. apply HT.
      intros.
      unfold extend. rewrite mextend_drop. destruct (eq_id_dec x x\theta). auto.
         rewrite H.
           clear - c n. induction c.
                simpl. rewrite neq_id; auto.
                simpl. destruct a. unfold extend. destruct (eq_id_dec i x\theta); auto.
    unfold R. fold R. split.
        auto.
     split. apply value_halts. apply v_abs.
     intros.
     destruct (R_halts H\theta) as [v \ [P \ Q]].
     pose proof (multistep_preserves_R _ _ _ P H0).
     apply multistep_preserves_R' with (msubst ((x, v) :: env0) t12).
        eapply T_App. eauto.
        apply R_typable_empty; auto.
        eapply multi_trans. eapply multistep_App2; eauto.
```

```
eapply multi_R.
simpl. rewrite subst_msubst.

Hint Constructors step.

## 7.3 Subtyping

Now we come to the interesting part. We begin by defining the subtyping relation and developing some of its important technical properties.

#### 7.3.1 Definition

The definition of subtyping is essentially just what we sketched in the motivating discussion, but we need to add well-formedness side conditions to some of the rules.

```
Inductive subtype : ty \rightarrow ty \rightarrow Prop :=
```

```
\begin{array}{l} | \ \mathsf{S\_Refl} : \ \forall \ T, \\ \mathbf{well\_formed\_ty} \ T \rightarrow \\ \mathbf{subtype} \ T \ T \\ | \ \mathsf{S\_Trans} : \ \forall \ S \ U \ T, \\ \mathbf{subtype} \ S \ U \rightarrow \\ \mathbf{subtype} \ U \ T \rightarrow \\ \mathbf{subtype} \ S \ T \end{array}
```

```
\mid \mathsf{S}_{\mathsf{-}}\mathsf{Top} : \forall S,
             well_formed_ty S \rightarrow
             subtype S TTop
      \mid S_A = S_1 = S_2 = S_2 = S_1 = S_2 = S_2 = S_2 = S_1 = S_2 = S_
             subtype T1 S1 \rightarrow
             subtype S2 T2 \rightarrow
             subtype (TArrow S1 S2) (TArrow T1 T2)
      | S_RcdWidth : \forall i T1 T2,
             well_formed_ty (TRCons i \ T1 \ T2) \rightarrow
             subtype (TRCons i T1 T2) TRNil
      | S_RcdDepth : \forall i S1 T1 Sr2 Tr2,
             subtype S1 T1 \rightarrow
             subtype Sr2 Tr2 \rightarrow
             record_ty Sr2 \rightarrow
             record_ty Tr2 \rightarrow
             subtype (TRCons i S1 Sr2) (TRCons i T1 Tr2)
      | S_RcdPerm : \forall i1 i2 T1 T2 Tr3,
             well_formed_ty (TRCons i1\ T1\ (TRCons\ i2\ T2\ Tr3)) \rightarrow
             i1 \neq i2 \rightarrow
             subtype (TRCons i1 T1 (TRCons i2 T2 Tr3))
                                       (TRCons i2 T2 (TRCons i1 T1 Tr3)).
Hint Constructors subtype.
Tactic Notation "subtype_cases" tactic(first) ident(c) :=
      first:
      [ Case_aux c "S_Refl" | Case_aux c "S_Trans" | Case_aux c "S_Top"
          Case_aux c "S_Arrow" | Case_aux c "S_RcdWidth"
       | Case\_aux \ c \ "S\_RcdDepth" | Case\_aux \ c \ "S\_RcdPerm" |.

    destruct (eq_id_dec i i\theta)... inversion H\theta; subst... Qed.
```

#### Field Lookup

Our record matching lemmas get a little more complicated in the presence of subtyping for two reasons: First, record types no longer necessarily describe the exact structure of corresponding terms. Second, reasoning by induction on **has\_type** derivations becomes harder in general, because **has\_type** is no longer syntax directed.

```
Lemma rcd_types_match : \forall \ S \ T \ i \ Ti, subtype S \ T \rightarrow
Tlookup i \ T = \text{Some} \ Ti \rightarrow
\exists \ Si, Tlookup i \ S = \text{Some} \ Si \land \text{subtype} \ Si \ Ti.
Proof with (eauto using wf_rcd_lookup).
intros S \ T \ i \ Ti \ Hsub \ Hget. generalize dependent Ti. subtype\_cases (induction Hsub) Case; intros Ti \ Hget;

```

Informal proof of progress:

Theorem : For any term t and type T, if  $\mathsf{empty} \vdash t : T$  then t is a value or t ==> t' for some term t'.

Proof: Let t and T be given such that  $\mathsf{empty} \vdash t : T$ . We go by induction on the typing derivation. Cases  $\mathsf{T}_{-}\mathsf{Abs}$  and  $\mathsf{T}_{-}\mathsf{RNil}$  are immediate because abstractions and  $\{\}$  are always values. Case  $\mathsf{T}_{-}\mathsf{Var}$  is vacuous because variables cannot be typed in the  $\mathsf{empty}$  context.

• If the last step in the typing derivation is by  $T_App$ , then there are terms t1 t2 and types T1 T2 such that t = t1 t2, T = T2, empty  $\vdash t1 : T1 \to T2$  and empty  $\vdash t2 : T1$ .

The induction hypotheses for these typing derivations yield that t1 is a value or steps, and that t2 is a value or steps. We consider each case:

- Suppose t1 ==> t1' for some term t1'. Then  $t1 \ t2 ==> t1' \ t2$  by  $ST\_App1$ .
- Otherwise t1 is a value.
  - \* Suppose t2 ==> t2' for some term t2'. Then t1 t2 ==> t1 t2' by rule  $ST\_App2$  because t1 is a value.
  - \* Otherwise, t2 is a value. By lemma  $canonical\_forms\_for\_arrow\_types$ ,  $t1 = \x:S1.s2$  for some x, S1, and s2. And  $(\x:S1.s2)$  t2 ==> [x:=t2]s2 by  $ST\_AppAbs$ , since t2 is a value.
- If the last step of the derivation is by  $T_{-}$ Proj, then there is a term tr, type Tr and label i such that t = tr.i, empty  $\vdash tr : Tr$ , and Tlookup i Tr =Some T.

The IH for the typing subderivation gives us that either tr is a value or it steps. If tr = tr for some term tr, then tr = tr by rule  $T_proj1$ .

Otherwise, tr is a value. In this case, lemma lookup\_field\_in\_value yields that there is a term ti such that tlookup i  $tr = \mathsf{Some}\ ti$ . It follows that tr.i ==> ti by rule  $\mathsf{ST\_ProjRcd}$ .

- If the final step of the derivation is by  $T_Sub$ , then there is a type S such that S <: T and  $empty \vdash t : S$ . The desired result is exactly the induction hypothesis for the typing subderivation.
- If the final step of the derivation is by T\_RCons, then there exist some terms t1 tr, types T1 Tr and a label t such that  $t = \{i=t1, tr\}$ ,  $T = \{i:T1, Tr\}$ , record\_tm tr, record\_tm Tr, empty  $\vdash t1 : T1$  and empty  $\vdash tr : Tr$ .

The induction hypotheses for these typing derivations yield that t1 is a value or steps, and that tr is a value or steps. We consider each case:

- Suppose t1 ==> t1' for some term t1'. Then  $\{i=t1, tr\} ==> \{i=t1', tr\}$  by rule  $ST_Rcd_Head$ .
- Otherwise t1 is a value.
  - \* Suppose tr ==> tr' for some term tr'. Then  $\{i=t1, tr\} ==> \{i=t1, tr'\}$  by rule  $ST_Rcd_Tail$ , since t1 is a value.
  - \* Otherwise, tr is also a value. So,  $\{i=t1, tr\}$  is a value by  $v\_rcons$ .

   Theorem: If t, t' are terms and T is a type such that empty \vdash t: T and t ==> t', then
empty \vdash t' : T.
   Proof: Let t and T be given such that empty \vdash t: T. We go by induction on the structure
of this typing derivation, leaving t' general. Cases T_Abs and T_RNil are vacuous because
```

Case "tproj".

abstractions and {} don't step. Case T\_Var is vacuous as well, since the context is empty.

• If the final step of the derivation is by  $T_App$ , then there are terms t1 t2 and types T1 T2 such that t = t1 t2, T = T2, empty  $\vdash t1 : T1 \to T2$  and empty  $\vdash t2 : T1$ .

By inspection of the definition of the step relation, there are three ways  $t1\ t2$  can step. Cases  $ST\_App1$  and  $ST\_App2$  follow immediately by the induction hypotheses for the typing subderivations and a use of  $T\_App$ .

Suppose instead t1 t2 steps by  $ST_AppAbs$ . Then  $t1 = \x: S.t12$  for some type S and term t12, and t' = [x:=t2]t12.

By Lemma abs\_arrow, we have T1 <: S and  $x:S1 \vdash s2 : T2$ . It then follows by lemma substitution\_preserves\_typing that empty  $\vdash [x:=t2]$  t12 : T2 as desired.

- If the final step of the derivation is by  $T_{-}Proj$ , then there is a term tr, type Tr and label i such that t = tr.i, empty  $\vdash tr : Tr$ , and Tlookup i Tr = Some T.
  - The IH for the typing derivation gives us that, for any term tr', if tr ==> tr' then  $empty \vdash tr'$  Tr. Inspection of the definition of the step relation reveals that there are two ways a projection can step. Case  $ST_{proj1}$  follows immediately by the IH.
  - Instead suppose tr.i steps by  $\mathsf{ST\_ProjRcd}$ . Then tr is a value and there is some term vi such that the threshold  $tr = \mathsf{Some}\ vi$  and t' = vi. But by lemma lookup\_field\_in\_value, empty  $\vdash vi : Ti$  as desired.
- If the final step of the derivation is by  $T_Sub$ , then there is a type S such that S <: T and  $empty \vdash t : S$ . The result is immediate by the induction hypothesis for the typing subderivation and an application of  $T_Sub$ .
- If the final step of the derivation is by T\_RCons, then there exist some terms t1 tr, types T1 Tr and a label t such that  $t = \{i=t1, tr\}$ ,  $T = \{i:T1, Tr\}$ , record\_tm tr, record\_tm Tr, empty  $\vdash t1 : T1$  and empty  $\vdash tr : Tr$ .

By the definition of the step relation, t must have stepped by  $ST_Rcd_Head$  or  $ST_Rcd_Tail$ . In the first case, the result follows by the IH for t1's typing derivation and  $T_RCons$ . In the second case, the result follows by the IH for t1's typing derivation,  $T_RCons$ , and a use of the t1's typing derivation, t1.

# 7.4.3 Exercises on Typing

Exercise: 2 stars, optional (variations) Each part of this problem suggests a different way of changing the definition of the STLC with records and subtyping. (These changes are not cumulative: each part starts from the original language.) In each part, list which properties (Progress, Preservation, both, or neither) become false. If a property becomes false, give a counterexample.

 $\bullet$  Suppose we add the following typing rule: Gamma |- t : S1->S2 S1 <: T1 T1 <: S1 S2 <: T2

- (T\_Funny1) Gamma |- t : T1->T2

• Suppose we add the following reduction rule:

 $- \qquad - (ST_Funny21)$   $\{\} ==> (\x:Top. x)$ 

• Suppose we add the following subtyping rule:

- ------ (S\_Funny3) {} <: Top->Top

• Suppose we add the following subtyping rule:

- ------- (S\_Funny4)
Top->Top <: {}

• Suppose we add the following evaluation rule:

- (ST\_Funny5) ({} t) ==> (t {})

• Suppose we add the same evaluation rule \*and\* a new typing rule:

- (ST\_Funny5)

empty  $\mid$ -  $\{\}$ : Top->Top

 $\bullet\,$  Suppose we \*change\* the arrow subtyping rule to: S1 <: T1 S2 <: T2

- (S\_Arrow') S1->S2 <: T1->T2

# Chapter 8

# Library Sub

# 8.1 Sub: Subtyping

Require Export MoreStlc.

# 8.2 Concepts

We now turn to the study of *subtyping*, perhaps the most characteristic feature of the static type systems of recently designed programming languages and a key feature needed to support the object-oriented programming style.

# 8.2.1 A Motivating Example

Suppose we are writing a program involving two record types defined as follows:

```
Person = {name:String, age:Nat}
Student = {name:String, age:Nat, gpa:Nat}
In the simply typed lamdba-calculus with records, the term
(\r:Person. (r.age)+1) {name="Pat",age=21,gpa=1}
```

is not typable: it involves an application of a function that wants a one-field record to an argument that actually provides two fields, while the T\_App rule demands that the domain type of the function being applied must match the type of the argument precisely.

But this is silly: we're passing the function a *better* argument than it needs! The only thing the body of the function can possibly do with its record argument r is project the field *age* from it: nothing else is allowed by the type, and the presence or absence of an extra *gpa* field makes no difference at all. So, intuitively, it seems that this function should be applicable to any record value that has at least an *age* field.

Looking at the same thing from another point of view, a record with more fields is "at least as good in any context" as one with just a subset of these fields, in the sense that any

value belonging to the longer record type can be used *safely* in any context expecting the shorter record type. If the context expects something with the shorter type but we actually give it something with the longer type, nothing bad will happen (formally, the program will not get stuck).

The general principle at work here is called *subtyping*. We say that "S is a subtype of T", informally written S <: T, if a value of type S can safely be used in any context where a value of type T is expected. The idea of subtyping applies not only to records, but to all of the type constructors in the language – functions, pairs, etc.

# 8.2.2 Subtyping and Object-Oriented Languages

Subtyping plays a fundamental role in many programming languages – in particular, it is closely related to the notion of *subclassing* in object-oriented languages.

An *object* in Java, C#, etc. can be thought of as a record, some of whose fields are functions ("methods") and some of whose fields are data values ("fields" or "instance variables"). Invoking a method m of an object o on some arguments a1..an consists of projecting out the m field of o and applying it to a1..an.

The type of an object can be given as either a *class* or an *interface*. Both of these provide a description of which methods and which data fields the object offers.

Classes and interfaces are related by the *subclass* and *subinterface* relations. An object belonging to a subclass (or subinterface) is required to provide all the methods and fields of one belonging to a superclass (or superinterface), plus possibly some more.

The fact that an object from a subclass (or sub-interface) can be used in place of one from a superclass (or super-interface) provides a degree of flexibility that is is extremely handy for organizing complex libraries. For example, a GUI toolkit like Java's Swing framework might define an abstract interface *Component* that collects together the common fields and methods of all objects having a graphical representation that can be displayed on the screen and that can interact with the user. Examples of such object would include the buttons, checkboxes, and scrollbars of a typical GUI. A method that relies only on this common interface can now be applied to any of these objects.

Of course, real object-oriented languages include many other features besides these. For example, fields can be updated. Fields and methods can be declared *private*. Classes also give *code* that is used when constructing objects and implementing their methods, and the code in subclasses cooperate with code in superclasses via *inheritance*. Classes can have static methods and fields, initializers, etc., etc.

To keep things simple here, we won't deal with any of these issues – in fact, we won't even talk any more about objects or classes. (There is a lot of discussion in *Types and Programming Languages*, if you are interested.) Instead, we'll study the core concepts behind the subclass / subinterface relation in the simplified setting of the STLC.

Of course, real OO languages have lots of other features...

- mutable fields
- private
- method inheritance
- static fields
- etc., etc.

We'll ignore all these and focus on core mechanisms.

# 8.2.3 The Subsumption Rule

Our goal for this chapter is to add subtyping to the simply typed lambda-calculus (with some of the basic extensions from MoreStlc). This involves two steps:

- Defining a binary subtype relation between types.
- Enriching the typing relation to take subtyping into account.

The second step is actually very simple. We add just a single rule to the typing relation: the so-called  $rule\ of\ subsumption$ : Gamma |- t : S S <: T

(T\_Sub) Gamma |- t : T This rule says, intuitively, that it is OK to "forget" some of what we know about a term. For example, we may know that t is a record with two fields (e.g.,  $S = \{x:A \rightarrow A, y:B \rightarrow B\}$ ), but choose to forget about one of the fields ( $T = \{y:B \rightarrow B\}$ ) so that we can pass t to a function that requires just a single-field record.

# 8.2.4 The Subtype Relation

The first step – the definition of the relation S <: T – is where all the action is. Let's look at each of the clauses of its definition.

## Structural Rules

To start off, we impose two "structural rules" that are independent of any particular type constructor: a rule of transitivity, which says intuitively that, if S is better than U and U is better than T, then S is better than T... S <: U U <: T

(S\_Trans) S <: T ... and a rule of *reflexivity*, since any type T is always just as good as itself:

 $(S_Refl) T <: T$ 

#### **Products**

Now we consider the individual type constructors, one by one, beginning with product types. We consider one pair to be "better than" another if each of its components is. S1 <: T1 S2 <: T2

```
(S_{-}Prod) S1*S2 <: T1*T2
```

#### Arrows

Suppose we have two functions f and g with these types:

```
f : C -> Student
g : (C -> Person) -> D
```

That is, f is a function that yields a record of type Student, and g is a (higher-order) function that expects its (function) argument to yield a record of type Person. Also suppose, even though we haven't yet discussed subtyping for records, that Student is a subtype of Person. Then the application g f is safe even though their types do not match up precisely, because the only thing g can do with f is to apply it to some argument (of type C); the result will actually be a Student, while g will be expecting a Person, but this is safe because the only thing g can then do is to project out the two fields that it knows about (name and age), and these will certainly be among the fields that are present.

This example suggests that the subtyping rule for arrow types should say that two arrow types are in the subtype relation if their results are: S2 <: T2

(S\_Arrow\_Co) S1->S2 <: S1->T2 We can generalize this to allow the arguments of the two arrow types to be in the subtype relation as well: T1 <: S1 S2 <: T2

(S\_Arrow) S1->S2 <: T1->T2 Notice that the argument types are subtypes "the other way round": in order to conclude that  $S1 \rightarrow S2$  to be a subtype of  $T1 \rightarrow T2$ , it must be the case that T1 is a subtype of S1. The arrow constructor is said to be *contravariant* in its first argument and *covariant* in its second.

Here is an example that illustrates this:

```
f : Person -> C
g : (Student -> C) -> D
```

The application g f is safe, because the only thing the body of g can do with f is to apply it to some argument of type Student. Since f requires records having (at least) the fields of a Person, this will always work. So Person  $\to C$  is a subtype of Student  $\to C$  since Student is a subtype of Person.

The intuition is that, if we have a function f of type  $S1 \rightarrow S2$ , then we know that f accepts elements of type S1; clearly, f will also accept elements of any subtype T1 of S1. The type of f also tells us that it returns elements of type S2; we can also view these results belonging

to any supertype T2 of S2. That is, any function f of type  $S1 \rightarrow S2$  can also be viewed as having type  $T1 \rightarrow T2$ .

Exercise: 2 stars (arrow\_sub\_wrong) Suppose we had incorrectly defined subtyping as covariant on both the right and the left of arrow types: S1 <: T1 S2 <: T2

(S\_Arrow\_wrong) S1->S2 <: T1->T2 Give a concrete example of functions  ${\sf f}$  and  ${\sf g}$  with types...

```
f : Student -> Nat
g : (Person -> Nat) -> Nat
```

... such that the application g f will get stuck during execution.

## Records

What about subtyping for record types?

The basic intuition about subtyping for record types is that it is always safe to use a "bigger" record in place of a "smaller" one. That is, given a record type, adding extra fields will always result in a subtype. If some code is expecting a record with fields x and y, it is perfectly safe for it to receive a record with fields x, y, and z; the z field will simply be ignored. For example,

```
{name:String, age:Nat, gpa:Nat} <: {name:String, age:Nat}
{name:String, age:Nat} <: {name:String}
{name:String} <: {}</pre>
```

This is known as "width subtyping" for records.

We can also create a subtype of a record type by replacing the type of one of its fields with a subtype. If some code is expecting a record with a field x of type T, it will be happy with a record having a field x of type S as long as S is a subtype of T. For example,

```
{x:Student} <: {x:Person}
```

This is known as "depth subtyping".

Finally, although the fields of a record type are written in a particular order, the order does not really matter. For example,

```
{name:String,age:Nat} <: {age:Nat,name:String}</pre>
```

This is known as "permutation subtyping".

We could formalize these requirements in a single subtyping rule for records as follows: for each jk in j1..jn, exists ip in i1..im, such that jk=ip and Sp <: Tk

(S\_Rcd) {i1:S1...im:Sm} <: {j1:T1...jn:Tn} That is, the record on the left should have all the field labels of the one on the right (and possibly more), while the types of the common fields should be in the subtype relation. However, this rule is rather heavy and hard to read. If we like, we can decompose it into three simpler rules, which can be combined using S\_Trans to achieve all the same effects.

First, adding fields to the end of a record type gives a subtype: n > m

(S\_RcdWidth) {i1:T1...in:Tn} <: {i1:T1...im:Tm} We can use S\_RcdWidth to drop later fields of a multi-field record while keeping earlier fields, showing for example that { age:Nat,name:String} <: {name:String}.

Second, we can apply subtyping inside the components of a compound record type: S1 <: T1 ... Sn <: Tn

(S\_RcdDepth)  $\{i1:S1...in:Sn\} <: \{i1:T1...in:Tn\}$  For example, we can use S\_RcdDepth and S\_RcdWidth together to show that  $\{y:Student, x:Nat\} <: \{y:Person\}$ .

Third, we need to be able to reorder fields. For example, we might expect that {name:String, gpa:Nat, age:Nat} <: Person. We haven't quite achieved this yet: using just S\_RcdDepth and S\_RcdWidth we can only drop fields from the end of a record type. So we need: {i1:S1...in:Sn} is a permutation of {i1:T1...in:Tn}

```
(S_RcdPerm) {i1:S1...in:Sn} <: {i1:T1...in:Tn}
```

It is worth noting that full-blown language designs may choose not to adopt all of these subtyping rules. For example, in Java:

- A subclass may not change the argument or result types of a method of its superclass (i.e., no depth subtyping or no arrow subtyping, depending how you look at it).
- Each class has just one superclass ("single inheritance" of classes).
- Each class member (field or method) can be assigned a single index, adding new indices "on the right" as more members are added in subclasses (i.e., no permutation for classes).
- A class may implement multiple interfaces so-called "multiple inheritance" of interfaces (i.e., permutation is allowed for interfaces).

## Top

Finally, it is natural to give the subtype relation a maximal element – a type that lies above every other type and is inhabited by all (well-typed) values. We do this by adding to the language one new type constant, called Top, together with a subtyping rule that places it above every other type in the subtype relation:

<sup>(</sup>S\_Top) S <: Top The Top type is an analog of the Object type in Java and C#.

## **Summary**

In summary, we form the STLC with subtyping by starting with the pure STLC (over some set of base types) and...

- adding a base type *Top*,
- adding the rule of subsumption Gamma |- t : S S <: T

to the typing relation, and

• defining a subtype relation as follows: S <: U U <: T

$$- \frac{}{n > m} (S_Arrow) S1->S2 <: T1->T2$$

$$\begin{array}{l} (S\_RcdDepth) \; \{i1:S1...in:Sn\} <: \; \{i1:T1...in:Tn\} \\ \{i1:S1...in:Sn\} \; is \; a \; permutation \; of \; \{i1:T1...in:Tn\} \end{array}$$

$$(S\_RcdPerm) \ \{i1:S1...in:Sn\} <: \ \{i1:T1...in:Tn\}$$

## 8.2.5 Exercises

Exercise: 1 star, optional (subtype\_instances\_tf\_1) Suppose we have types S, T, U, and V with S <: T and U <: V. Which of the following subtyping assertions are then true? Write true or false after each one. (A, B, and C here are base types.)

- $T \rightarrow S <: T \rightarrow S$
- $Top \rightarrow U <: S \rightarrow Top$
- $(C \rightarrow C) \rightarrow (A \times B) <: (C \rightarrow C) \rightarrow (\mathit{Top} \times B)$
- $\bullet \quad T {\rightarrow} \, T {\rightarrow} \, U \, <: \, \mathsf{S} {\rightarrow} \mathsf{S} {\rightarrow} \, V$
- $(T \rightarrow T)$ -> $U <: (S \rightarrow S)$ ->V
- $((T \rightarrow S)->T)->U <: ((S \rightarrow T)->S)->V$
- $S \times V <: T \times U$

Exercise: 2 stars (subtype\_order) The following types happen to form a linear order with respect to subtyping:

- Top
- $Top \rightarrow \mathsf{Student}$
- Student  $\rightarrow$  Person
- Student  $\rightarrow Top$
- $\bullet$  Person  $\rightarrow$  Student

Write these types in order from the most specific to the most general.

Where does the type  $Top \rightarrow Top \rightarrow Student$  fit into this order?

Exercise: 1 star (subtype\_instances\_tf\_2) Which of the following statements are true? Write true or false after each one. forall S T, S <: T -> S->S <: T->T

for all S, S <: A->A -> exists T, S = T->T /\ T <: A

forall S T1 T1, (S <: T1 -> T2) -> exists S1 S2, S = S1 -> S2 /\ T1 <: S1 /\ S2 <: T2 exists S, S <: S->S

exists S, S->S <: S

forall S T2 T2, S <: T1\*T2 -> exists S1 S2, S = S1\*S2 /\ S1 <: T1 /\ S2 <: T2  $\square$ 

Exercise: 1 star (subtype\_concepts\_tf) Which of the following statements are true, and which are false?

- There exists a type that is a supertype of every other type.
- There exists a type that is a subtype of every other type.
- There exists a pair type that is a supertype of every other pair type.
- There exists a pair type that is a subtype of every other pair type.
- There exists an arrow type that is a supertype of every other arrow type.
- There exists an arrow type that is a subtype of every other arrow type.
- There is an infinite descending chain of distinct types in the subtype relation—that is, an infinite sequence of types S0, S1, etc., such that all the Si's are different and each S(i+1) is a subtype of Si.
- There is an infinite ascending chain of distinct types in the subtype relation—that is, an infinite sequence of types S0, S1, etc., such that all the Si's are different and each S(i+1) is a supertype of Si.

**Exercise: 2 stars (proper\_subtypes)** Is the following statement true or false? Briefly explain your answer. forall T,  $\tilde{}$  (exists n, T = TBase n) -> exists S, S <: T /\ S <> T ]]  $\square$ 

## Exercise: 2 stars (small\_large\_1)

- What is the *smallest* type T ("smallest" in the subtype relation) that makes the following assertion true? (Assume we have Unit among the base types and unit as a constant of this type.) empty  $|-(\p:T^*Top.\ p.fst)$  (( $\z:A.z$ ), unit): A->A
- $\bullet$  What is the *largest* type T that makes the same assertion true?

Exercise: 2 stars (small\_large\_2)

- What is the *smallest* type T that makes the following assertion true? empty  $|-(\p:(A->A * B->B). p) ((\z:A.z), (\z:B.z)) : T$
- What is the *largest* type T that makes the same assertion true?

- What is the *smallest* type T that makes the following assertion true? a:A |- (\p:(A\*T). (p.snd) (p.fst)) (a , \z:A.z) : A
- What is the *largest* type T that makes the same assertion true?

## Exercise: 2 stars (small\_large\_4)

- What is the *smallest* type T that makes the following assertion true? exists S, empty  $|-(\protect\pro$
- $\bullet$  What is the *largest* type T that makes the same assertion true?

**Exercise: 2 stars (smallest\_1)** What is the *smallest* type T that makes the following assertion true? exists S, exists t, empty [-(x:T. x x) t: S]

**Exercise: 2 stars (smallest\_2)** What is the *smallest* type T that makes the following assertion true? empty  $[-(x:Top. x) ((z:A.z), (z:B.z)) : T]] <math>\Box$ 

**Exercise:** 3 stars, optional (count\_supertypes) How many supertypes does the record type  $\{x:A, y:C\rightarrow C\}$  have? That is, how many different types T are there such that  $\{x:A, y:C\rightarrow C\}$  <: T? (We consider two types to be different if they are written differently, even if each is a subtype of the other. For example,  $\{x:A,y:B\}$  and  $\{y:B,x:A\}$  are different.)

Exercise: 2 stars (pair\_permutation) The subtyping rule for product types S1 <: T1 S2 <: T2

(S\_Prod) S1\*S2 <: T1\*T2 intuitively corresponds to the "depth" subtyping rule for records. Extending the analogy, we might consider adding a "permutation" rule

T1\*T2 <: T2\*T1 for products. Is this a good idea? Briefly explain why or why not.  $\Box$ 

# 8.3 Formal Definitions

Most of the definitions – in particular, the syntax and operational semantics of the language – are identical to what we saw in the last chapter. We just need to extend the typing relation with the subsumption rule and add a new Inductive definition for the subtyping relation. Let's first do the identical bits.

## 8.3.1 Core Definitions

## **Syntax**

For the sake of more interesting examples below, we'll allow an arbitrary set of additional base types like String, Float, etc. We won't bother adding any constants belonging to these types or any operators on them, but we could easily do so.

In the rest of the chapter, we formalize just base types, booleans, arrow types, *Unit*, and *Top*, omitting record types and leaving product types as an exercise.

```
Inductive ty : Type :=
    TTop: ty
    TBool: ty
    TBase : id \rightarrow ty
    TArrow : ty \rightarrow ty \rightarrow ty
    TUnit: ty
Tactic Notation "T_cases" tactic(first) ident(c) :=
  first;
   Case_aux c "TTop" | Case_aux c "TBool"
    Case_aux c "TBase" | Case_aux c "TArrow"
    Case_aux c "TUnit" |
Inductive tm : Type :=
   \mathsf{tvar}:\mathsf{id}\to\mathsf{tm}
    tapp: tm \rightarrow tm \rightarrow tm
   tabs : id \rightarrow ty \rightarrow tm \rightarrow tm
    ttrue: tm
    tfalse: tm
    \mathsf{tif}: \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}
   tunit : tm
Tactic Notation "t_cases" tactic(first) ident(c) :=
  first:
  [ Case_aux c "tvar" | Case_aux c "tapp"
    Case\_aux \ c "tabs" | Case\_aux \ c "ttrue"
    Case_aux c "tfalse" | Case_aux c "tif"
    Case\_aux \ c "tunit"
```

#### Substitution

The definition of substitution remains the same as for the ordinary STLC.

```
Fixpoint subst (x:id) (s:tm) (t:tm) : tm :=
  match t with
  \mid tvar y \Rightarrow
        if eq_id_dec x y then s else t
  | tabs y T t1 \Rightarrow
        tabs y \ T \ (if \ eq_id_dec \ x \ y \ then \ t1 \ else \ (subst \ x \ s \ t1))
  | tapp t1 t2 \Rightarrow
        tapp (subst x \ s \ t1) (subst x \ s \ t2)
  \mid ttrue \Rightarrow
        ttrue
  | tfalse \Rightarrow
        tfalse
  \mid tif t1 \ t2 \ t3 \Rightarrow
        tif (subst x \ s \ t1) (subst x \ s \ t2) (subst x \ s \ t3)
  \mid tunit \Rightarrow
        tunit
  end.
Notation "'[' x := s ']' t" := (subst x s t) (at level 20).
Reduction
Likewise the definitions of the value property and the step relation.
Inductive value : tm \rightarrow Prop :=
  | v_abs : \forall x T t,
        value (tabs x T t)
  | v_true :
        value ttrue
  | v_false :
        value tfalse
  | v_unit :
        value tunit
Hint Constructors value.
Reserved Notation "t1'==>'t2" (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_AppAbs : \forall x T t12 v2,
            value v2 \rightarrow
            (tapp (tabs x T t12) v2) ==> [x:=v2] t12
  | ST\_App1 : \forall t1 t1' t2,
            t1 \Longrightarrow t1' \rightarrow
            (tapp t1 t2) ==> (tapp t1' t2)
```

```
| ST\_App2 : \forall v1 t2 t2',
           value v1 \rightarrow
           t2 ==> t2' \rightarrow
           (tapp v1 t2) ==> (tapp v1 t2')
  \mid ST_I f True : \forall t1 t2,
       (tif ttrue t1 t2) ==> t1
  | ST_IfFalse : \forall t1 t2,
       (tif tfalse t1 t2) ==> t2
  \mid ST_If : \forall t1 t1' t2 t3,
       t1 ==> t1' \rightarrow
       (tif t1 t2 t3) ==> (tif t1' t2 t3)
where "t1 '==>' t2" := (step t1 \ t2).
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first;
  [ Case_aux c "ST_AppAbs" | Case_aux c "ST_App1"
    Case_aux c "ST_App2" | Case_aux c "ST_IfTrue"
    Case\_aux \ c "ST_IfFalse" | Case\_aux \ c "ST_If"
```

Hint Constructors step.

# 8.3.2 Subtyping

Now we come to the most interesting part. We begin by defining the subtyping relation and developing some of its important technical properties.

The definition of subtyping is just what we sketched in the motivating discussion.

Reserved Notation "T'<: U" (at level 40).

```
Inductive subtype: \mathbf{ty} \to \mathbf{ty} \to \mathsf{Prop} := | \mathsf{S}_{\mathsf{Refl}} : \forall \ T, \\ T <: \ T \\ | \mathsf{S}_{\mathsf{Trans}} : \forall \ S \ U \ T, \\ S <: \ U \to \\ U <: \ T \to \\ S <: \ T \\ | \mathsf{S}_{\mathsf{Top}} : \forall \ S, \\ S <: \ \mathsf{TTop} \\ | \mathsf{S}_{\mathsf{Arrow}} : \forall \ S1 \ S2 \ T1 \ T2, \\ T1 <: \ S1 \to \\ S2 <: \ T2 \to \\ (\mathsf{TArrow} \ S1 \ S2) <: \ (\mathsf{TArrow} \ T1 \ T2) \\ \mathsf{where} \ "T \ '<: \ U" := (\mathsf{subtype} \ T \ U).
```

Note that we don't need any special rules for base types: they are automatically subtypes

```
of themselves (by S_Refl) and Top (by S_Top), and that's all we want.
Hint Constructors subtype.
Tactic Notation "subtype_cases" tactic(first) ident(c) :=
  first;
   Case_aux c "S_Refl" | Case_aux c "S_Trans"
   Case_aux c "S_Top" | Case_aux c "S_Arrow"
Module EXAMPLES.
Notation x := (Id \ 0).
Notation y := (Id 1).
Notation z := (Id 2).
Notation A := (TBase (Id 6)).
Notation B := (TBase (Id 7)).
Notation C := (TBase (Id 8)).
Notation String := (TBase (Id 9)).
Notation Float := (TBase (Id 10)).
Notation Integer := (TBase (Id 11)).
Exercise: 2 stars, optional (subtyping_judgements) (Do this exercise after you have
added product types to the language, at least up to this point in the file).
   Using the encoding of records into pairs, define pair types representing the record types
Person := { name : String } Student := { name : String ; gpa : Float } Employee := { name

# 8.4 Properties

The fundamental properties of the system that we want to check are the same as always: progress and preservation. Unlike the extension of the STLC with references, we don't need to change the *statements* of these properties to take subtyping into account. However, their proofs do become a little bit more involved.

# 8.4.1 Inversion Lemmas for Subtyping

Before we look at the properties of the typing relation, we need to record a couple of critical structural properties of the subtype relation:

- Bool is the only subtype of Bool
- every subtype of an arrow type is an arrow type.

These are called *inversion lemmas* because they play the same role in later proofs as the built-in **inversion** tactic: given a hypothesis that there exists a derivation of some subtyping statement S <: T and some constraints on the shape of S and/or T, each one reasons about what this derivation must look like to tell us something further about the shapes of S and T and the existence of subtype relations between their parts.

```
Exercise: 2 stars, optional (sub_inversion_Bool) Lemma sub_inversion_Bool: \forall U,
      U <: \mathsf{TBool} \to
        U = \mathsf{TBool}.
Proof with auto.

  remember TBool as V.
   Admitted.
Exercise: 3 stars, optional (sub_inversion_arrow) Lemma sub_inversion_arrow: \forall U
V1 V2.
      U <: (\mathsf{TArrow}\ V1\ V2) \rightarrow
      \exists U1, \exists U2,
        U = (\mathsf{TArrow}\ U1\ U2) \land (V1 \lt: U1) \land (U2 \lt: V2).
Proof with eauto.
  intros U V1 V2 Hs.
  remember (TArrow V1 V2) as V.
  generalize dependent V2. generalize dependent V1.
   Admitted.
```

#### 8.4.2 Canonical Forms

We'll see first that the proof of the progress theorem doesn't change too much – we just need one small refinement. When we're considering the case where the term in question is an application t1 t2 where both t1 and t2 are values, we need to know that t1 has the form of a lambda-abstraction, so that we can apply the  $ST\_AppAbs$  reduction rule. In the ordinary STLC, this is obvious: we know that t1 has a function type  $T11 \rightarrow T12$ , and there is only one rule that can be used to give a function type to a value – rule  $T\_Abs$  – and the form of the conclusion of this rule forces t1 to be an abstraction.

In the STLC with subtyping, this reasoning doesn't quite work because there's another rule that can be used to show that a value has a function type: subsumption. Fortunately, this possibility doesn't change things much: if the last rule used to show  $Gamma \vdash t1$ :  $T11 \rightarrow T12$  is subsumption, then there is some sub-derivation whose subject is also t1, and we can reason by induction until we finally bottom out at a use of  $T_Abs$ .

This bit of reasoning is packaged up in the following lemma, which tells us the possible "canonical forms" (i.e. values) of function type.

```
Exercise: 3 stars, optional (canonical_forms_of_arrow_types) Lemma canonical_forms_of_arrow_types)
: \forall Gamma \ s \ T1 \ T2,
  Gamma \vdash s \setminus in (TArrow T1 T2) \rightarrow
  value s \rightarrow
  \exists x, \exists S1, \exists s2,
      s = tabs \ x \ S1 \ s2.
Proof with eauto.
    Admitted.
    Similarly, the canonical forms of type Bool are the constants true and false.
Lemma canonical_forms_of_Bool : \forall Gamma \ s,
  Gamma \vdash s \setminus in \mathsf{TBool} \to
  value s \rightarrow
  (s = \mathsf{ttrue} \lor s = \mathsf{tfalse}).
Proof with eauto.
  intros Gamma s Hty Hv.
  remember TBool as T.
  has\_type\_cases (induction Hty) Case; try solve by inversion...
  Case "T_Sub".
     subst. apply sub_inversion_Bool in H. subst...
Qed.
```

# 8.4.3 Progress

The proof of progress proceeds like the one for the pure STLC, except that in several places we invoke canonical forms lemmas...

Theorem (Progress): For any term t and type T, if  $\mathsf{empty} \vdash t : T$  then t is a value or t = t for some term t.

*Proof*: Let t and T be given, with empty  $\vdash t$ : T. Proceed by induction on the typing derivation.

The cases for T\_Abs, T\_Unit, T\_True and T\_False are immediate because abstractions, unit, true, and false are already values. The T\_Var case is vacuous because variables cannot be typed in the empty context. The remaining cases are more interesting:

- If the last step in the typing derivation uses rule  $T_{-}App$ , then there are terms t1 t2 and types T1 and T2 such that t = t1 t2, T = T2, empty  $\vdash t1 : T1 \to T2$ , and empty  $\vdash t2 : T1$ . Moreover, by the induction hypothesis, either t1 is a value or it steps, and either t2 is a value or it steps. There are three possibilities to consider:
  - Suppose t1 ==> t1' for some term t1'. Then t1 t2 ==> t1' t2 by  $ST\_App1$ .
  - Suppose t1 is a value and t2 ==> t2' for some term t2'. Then t1 t2 ==> t1 t2' by rule  $ST\_App2$  because t1 is a value.
  - Finally, suppose t1 and t2 are both values. By Lemma  $canonical\_forms\_for\_arrow\_types$ , we know that t1 has the form  $\x:S1.s2$  for some x, S1, and S2. But then  $(\x:S1.s2)$  t2 ==> [x:=t2]s2 by  $ST\_AppAbs$ , since t2 is a value.
- If the final step of the derivation uses rule  $T_{-}$ lf, then there are terms t1, t2, and t3 such that t = if t1 then t2 else t3, with empty  $\vdash t1$ : Bool and with empty  $\vdash t2$ : T and empty  $\vdash t3$ : T. Moreover, by the induction hypothesis, either t1 is a value or it steps.
  - If t1 is a value, then by the canonical forms lemma for booleans, either t1 = true or t1 = false. In either case, t can step, using rule ST\_lfTrue or ST\_lfFalse.
  - If t1 can step, then so can t, by rule  $ST_If$ .
- If the final step of the derivation is by T\_Sub, then there is a type S such that S <: T
  and empty ⊢ t : S. The desired result is exactly the induction hypothesis for the typing
  subderivation.</li>

```

# 8.4.4 Inversion Lemmas for Typing

The proof of the preservation theorem also becomes a little more complex with the addition of subtyping. The reason is that, as with the "inversion lemmas for subtyping" above, there are a number of facts about the typing relation that are "obvious from the definition" in the pure STLC (and hence can be obtained directly from the inversion tactic) but that require real proofs in the presence of subtyping because there are multiple ways to derive the same has\_type statement.

The following "inversion lemma" tells us that, if we have a derivation of some typing statement  $Gamma \vdash \x:S1.t2: T$  whose subject is an abstraction, then there must be some subderivation giving a type to the body t2.

Lemma: If  $Gamma \vdash \x:S1.t2: T$ , then there is a type S2 such that  $Gamma, x:S1 \vdash t2: S2$  and  $S1 \rightarrow S2 <: T$ .

(Notice that the lemma does not say, "then T itself is an arrow type" – this is tempting, but false!)

*Proof*: Let Gamma, x, S1, t2 and T be given as described. Proceed by induction on the derivation of  $Gamma \vdash \xspace \xspace \xspace \xspace T_Var$ ,  $T_App$ , are vacuous as those rules cannot

be used to give a type to a syntactic abstraction.

- If the last step of the derivation is a use of  $T_Abs$  then there is a type T12 such that  $T = S1 \rightarrow T12$  and Gamma,  $x:S1 \vdash t2 : T12$ . Picking T12 for S2 gives us what we need:  $S1 \rightarrow T12 <: S1 \rightarrow T12$  follows from  $S_Refl.$
- If the last step of the derivation is a use of T\_Sub then there is a type S such that S <: T and  $Gamma \vdash \x:S1.t2 : S$ . The IH for the typing subderivation tell us that there is some type S2 with  $S1 \rightarrow S2 <: S$  and Gamma,  $x:S1 \vdash t2 : S2$ . Picking type S2 gives us what we need, since  $S1 \rightarrow S2 <: T$  then follows by S\_Trans.

```
Lemma typing_inversion_abs : \forall Gamma \ x \ S1 \ t2 \ T,
      Gamma \vdash (tabs \ x \ S1 \ t2) \setminus in \ T \rightarrow

## 8.4.6 Substitution

The *substitution lemma* is proved along the same lines as for the pure STLC. The only significant change is that there are several places where, instead of the built-in inversion

tactic, we need to use the inversion lemmas that we proved above to extract structural information from assumptions about the well-typedness of subterms.

```
Lemma substitution_preserves_typing : \forall \ Gamma \ x \ U \ v \ t \ S,
      (extend Gamma \ x \ U) \vdash t \setminus in \ S \rightarrow

## 8.4.7 Preservation

The proof of preservation now proceeds pretty much as in earlier chapters, using the substitution lemma at the appropriate point and again using inversion lemmas from above to extract structural information from typing assumptions.

Theorem (Preservation): If t, t' are terms and T is a type such that  $\mathsf{empty} \vdash t : T$  and t ==> t', then  $\mathsf{empty} \vdash t' : T$ .

*Proof*: Let t and T be given such that  $\mathsf{empty} \vdash t : T$ . We go by induction on the structure of this typing derivation, leaving t' general. The cases  $\mathsf{T\_Abs}$ ,  $\mathsf{T\_Unit}$ ,  $\mathsf{T\_True}$ , and  $\mathsf{T\_False}$  cases are vacuous because abstractions and constants don't step. Case  $\mathsf{T\_Var}$  is vacuous as well, since the context is empty.

• If the final step of the derivation is by  $\mathsf{T}_{-}\mathsf{App}$ , then there are terms t1 t2 and types T1 T2 such that t=t1 t2, T=T2, empty  $\vdash t1:T1\to T2$  and empty  $\vdash t2:T1$ .

By inspection of the definition of the step relation, there are three ways  $t1\ t2$  can step. Cases  $ST\_App1$  and  $ST\_App2$  follow immediately by the induction hypotheses for the typing subderivations and a use of  $T\_App$ .

Suppose instead t1 t2 steps by  $ST_AppAbs$ . Then  $t1 = \x: S.t12$  for some type S and term t12, and t' = [x:=t2]t12.

By lemma abs\_arrow, we have T1 <: S and  $x:S1 \vdash s2 : T2$ . It then follows by the substitution lemma (substitution\_preserves\_typing) that empty  $\vdash [x:=t2]$  t12 : T2 as

desired.

- If the final step of the derivation uses rule  $T_{-}$ lf, then there are terms t1, t2, and t3 such that t = if t1 then t2 else t3, with empty  $\vdash t1$ : Bool and with empty  $\vdash t2$ : T and empty  $\vdash t3$ : T. Moreover, by the induction hypothesis, if t1 steps to t1' then empty  $\vdash t1$ ': Bool. There are three cases to consider, depending on which rule was used to show t ==> t'.
  - \* If t ==> t' by rule ST\_If, then t' = if t1' then t2 else t3 with t1 ==> t1'. By the induction hypothesis, empty  $\vdash t1'$ : Bool, and so empty  $\vdash t'$ : T by T\_If.
  - \* If t ==> t' by rule ST\_IfTrue or ST\_IfFalse, then either t' = t2 or t' = t3, and empty  $\vdash t'$ : T follows by assumption.
- If the final step of the derivation is by  $T_Sub$ , then there is a type S such that S <: T and  $empty \vdash t : S$ . The result is immediate by the induction hypothesis for the typing subderivation and an application of  $T_Sub$ .  $\square$

```
Theorem preservation : \forall t t' T,
     empty \vdash t \setminus in T \rightarrow

# 8.4.8 Records, via Products and Top

This formalization of the STLC with subtyping has omitted record types, for brevity. If we want to deal with them more seriously, we have two choices.

First, we can treat them as part of the core language, writing down proper syntax, typing, and subtyping rules for them. Chapter RecordSub shows how this extension works.

On the other hand, if we are treating them as a derived form that is desugared in the parser, then we shouldn't need any new rules: we should just check that the existing rules

for subtyping product and *Unit* types give rise to reasonable rules for record subtyping via this encoding. To do this, we just need to make one small change to the encoding described earlier: instead of using *Unit* as the base case in the encoding of tuples and the "don't care" placeholder in the encoding of records, we use *Top*. So:

```
{a:Nat, b:Nat} ----> {Nat,Nat} i.e. (Nat,(Nat,Top)) {c:Nat, a:Nat} ----> {Nat,Top,Nat} i.e. (Nat,(Top,(Nat,Top)))
```

The encoding of record values doesn't change at all. It is easy (and instructive) to check that the subtyping rules above are validated by the encoding. For the rest of this chapter, we'll follow this encoding-based approach.

#### 8.4.9 Exercises

Exercise: 2 stars (variations) Each part of this problem suggests a different way of changing the definition of the STLC with Unit and subtyping. (These changes are not cumulative: each part starts from the original language.) In each part, list which properties (Progress, Preservation, both, or neither) become false. If a property becomes false, give a counterexample.

 $\bullet$  Suppose we add the following typing rule: Gamma |- t : S1->S2 S1 <: T1 T1 <: S1 S2 <: T2

$$-$$
 (T\_Funny1) Gamma |- t : T1->T2

• Suppose we add the following reduction rule:

$$- \qquad - (ST_Funny21)$$
unit ==> (\x:Top. x)

• Suppose we add the following subtyping rule:

• Suppose we add the following subtyping rule:

• Suppose we add the following evaluation rule:

$$(unit t) ==> (t unit)$$

• Suppose we add the same evaluation rule and a new typing rule:

• Suppose we *change* the arrow subtyping rule to: S1 <: T1 S2 <: T2

8.5 Exercise: Adding Products

**Exercise:** 4 stars, optional (products) Adding pairs, projections, and product types to the system we have defined is a relatively straightforward matter. Carry out this extension:

- Add constructors for pairs, first and second projections, and product types to the definitions of **ty** and **tm**. (Don't forget to add corresponding cases to  $T_{-}cases$  and  $t_{-}cases$ .)
- Extend the well-formedness relation in the obvious way.
- Extend the operational semantics with the same reduction rules as in the last chapter.
- Extend the subtyping relation with this rule: S1 <: T1 S2 <: T2

- Extend the typing relation with the same rules for pairs and projections as in the last chapter.
- Extend the proofs of progress, preservation, and all their supporting lemmas to deal with the new constructs. (You'll also need to add some completely new lemmas.)  $\Box$

# Chapter 9

# Library References

# 9.1 References: Typing Mutable References

Require Export Smallstep.

So far, we have considered a variety of *pure* language features, including functional abstraction, basic types such as numbers and booleans, and structured types such as records and variants. These features form the backbone of most programming languages – including purely functional languages such as Haskell, "mostly functional" languages such as ML, imperative languages such as C, and object-oriented languages such as Java.

Most practical programming languages also include various *impure* features that cannot be described in the simple semantic framework we have used so far. In particular, besides just yielding results, evaluation of terms in these languages may assign to mutable variables (reference cells, arrays, mutable record fields, etc.), perform input and output to files, displays, or network connections, make non-local transfers of control via exceptions, jumps, or continuations, engage in inter-process synchronization and communication, and so on. In the literature on programming languages, such "side effects" of computation are more generally referred to as *computational effects*.

In this chapter, we'll see how one sort of computational effect – mutable references – can be added to the calculi we have studied. The main extension will be dealing explicitly with a *store* (or *heap*). This extension is straightforward to define; the most interesting part is the refinement we need to make to the statement of the type preservation theorem.

#### 9.1.1 Definitions

Pretty much every programming language provides some form of assignment operation that changes the contents of a previously allocated piece of storage. (Coq's internal language is a rare exception!)

In some languages – notably ML and its relatives – the mechanisms for name-binding and those for assignment are kept separate. We can have a variable x whose *value* is the number 5, or we can have a variable y whose value is a *reference* (or *pointer*) to a mutable

cell whose current contents is 5. These are different things, and the difference is visible to the programmer. We can add x to another number, but not assign to it. We can use y directly to assign a new value to the cell that it points to (by writing y:=84), but we cannot use it directly as an argument to an operation like +. Instead, we must explicitly *dereference* it, writing !y to obtain its current contents.

In most other languages – in particular, in all members of the C family, including Java – every variable name refers to a mutable cell, and the operation of dereferencing a variable to obtain its current contents is implicit.

For purposes of formal study, it is useful to keep these mechanisms separate. The development in this chapter will closely follow ML's model. Applying the lessons learned here to C-like languages is a straightforward matter of collapsing some distinctions and rendering some operations such as dereferencing implicit instead of explicit.

In this chapter, we study adding mutable references to the simply-typed lambda calculus with natural numbers.

## 9.1.2 Syntax

Module STLCREF.

The basic operations on references are allocation, dereferencing, and assignment.

- To allocate a reference, we use the *ref* operator, providing an initial value for the new cell. For example, *ref* 5 creates a new cell containing the value 5, and evaluates to a reference to that cell.
- To read the current value of this cell, we use the dereferencing operator!; for example, !(ref 5) evaluates to 5.
- To change the value stored in a cell, we use the assignment operator. If r is a reference, r := 7 will store the value 7 in the cell referenced by r. However, r := 7 evaluates to the trivial value unit; it exists only to have the *side effect* of modifying the contents of a cell.

#### **Types**

We start with the simply typed lambda calculus over the natural numbers. To the base natural number type and arrow types we need to add two more types to deal with references. First, we need the *unit type*, which we will use as the result type of an assignment operation. We then add *reference types*. If T is a type, then  $Ref\ T$  is the type of references which point to a cell holding values of type T.  $T := Nat \mid Unit \mid T \rightarrow T \mid Ref\ T$ 

```
Inductive ty : Type :=
    | TNat : ty
    | TUnit : ty
```

```
\begin{array}{l} \mathsf{TArrow}:\,\mathsf{ty}\to\mathsf{ty}\to\mathsf{ty}\\ \mathsf{TRef}:\,\mathsf{ty}\to\mathsf{ty}. \end{array}
```

#### **Terms**

Besides variables, abstractions, applications, natural-number-related terms, and unit, we need four more sorts of terms in order to handle mutable references:

Inductive tm : Type :=

```
 | \ \mathsf{tvar} : \ \mathsf{id} \to \mathsf{tm} \\ | \ \mathsf{tapp} : \ \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \\ | \ \mathsf{tabs} : \ \mathsf{id} \to \mathsf{ty} \to \mathsf{tm} \to \mathsf{tm} \\ | \ \mathsf{tnat} : \ \mathsf{nat} \to \mathsf{tm} \\ | \ \mathsf{tsucc} : \ \mathsf{tm} \to \mathsf{tm} \\ | \ \mathsf{tpred} : \ \mathsf{tm} \to \mathsf{tm} \\ | \ \mathsf{tmult} : \ \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \\ | \ \mathsf{tif0} : \ \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \\ | \ \mathsf{tunit} : \ \mathsf{tm} \\ | \ \mathsf{tref} : \ \mathsf{tm} \to \mathsf{tm} \\ | \ \mathsf{tderef} : \ \mathsf{tm} \to \mathsf{tm} \\ | \ \mathsf{tassign} : \ \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \\ | \ \mathsf{tloc} : \ \mathsf{nat} \to \mathsf{tm}.
```

Intuitively...

- $ref\ t$  (formally, tref t) allocates a new reference cell with the value t and evaluates to the location of the newly allocated cell;
- !t (formally, tderef t) evaluates to the contents of the cell referenced by t;
- t1 := t2 (formally, tassign  $t1 \ t2$ ) assigns t2 to the cell referenced by t1; and
- I (formally, tloc I) is a reference to the cell at location I. We'll discuss locations later.

In informal examples, we'll also freely use the extensions of the STLC developed in the MoreStlc chapter; however, to keep the proofs small, we won't bother formalizing them again here. It would be easy to do so, since there are no very interesting interactions between those features and references.

```
Tactic Notation "t_cases" tactic(first) ident(c) :=
    first;
    [ Case_aux c "tvar" | Case_aux c "tapp"
        | Case_aux c "tabs" | Case_aux c "tzero"
        | Case_aux c "tsucc" | Case_aux c "tpred"
        | Case_aux c "tmult" | Case_aux c "tif0"
        | Case_aux c "tunit" | Case_aux c "tref"
        | Case_aux c "tderef" | Case_aux c "tassign"
        | Case_aux c "tloc" ].

Module EXAMPLEVARIABLES.

Definition x := Id 0.
Definition r := Id 2.
Definition s := Id 3.
End EXAMPLEVARIABLES.
```

#### Typing (Preview)

Informally, the typing rules for allocation, dereferencing, and assignment will look like this: Gamma |- t1 : T1

```
(T_Ref) Gamma |- ref t1 : Ref T1
Gamma |- t1 : Ref T11

(T_Deref) Gamma |- !t1 : T11
Gamma |- t1 : Ref T11 Gamma |- t2 : T11
```

 $(T_Assign)$  Gamma |-t1| = t2: Unit The rule for locations will require a bit more machinery, and this will motivate some changes to the other rules; we'll come back to this later.

#### Values and Substitution

Besides abstractions and numbers, we have two new types of values: the unit value, and locations.

```
Inductive value : tm \rightarrow Prop := | v_abs : \forall x \ T \ t,
value (tabs x \ T \ t)
| v_nat : \forall n,
value (tnat n)
| v_unit : v_not : \forall l,
```

```
value (tloc l).
```

Hint Constructors value.

Extending substitution to handle the new syntax of terms is straightforward.

```
Fixpoint subst (x:id) (s:tm) (t:tm) : tm :=
   match t with
   | tvar x' \Rightarrow
         if eq_id_dec x x' then s else t
   | tapp t1 t2 \Rightarrow
         tapp (subst x \ s \ t1) (subst x \ s \ t2)
   | tabs x' T t1 \Rightarrow
         if eq_id_dec x x' then t else tabs x' T (subst x s t1)
   \mid tnat n \Rightarrow
   | tsucc t1 \Rightarrow
         tsucc (subst x \ s \ t1)
   | tpred t1 \Rightarrow
         tpred (subst x \ s \ t1)
   | tmult t1 t2 \Rightarrow
         tmult (subst x \ s \ t1) (subst x \ s \ t2)
   | tif0 t1 t2 t3 \Rightarrow
         tif0 (subst x \ s \ t1) (subst x \ s \ t2) (subst x \ s \ t3)
   \mid tunit \Rightarrow
         t
   \mid \mathsf{tref} \ t1 \Rightarrow
         tref (subst x \ s \ t1)
   | tderef t1 \Rightarrow
         tderef (subst x \ s \ t1)
   | tassign t1 t2 \Rightarrow
         tassign (subst x \ s \ t1) (subst x \ s \ t2)
   | tloc _{-} \Rightarrow
         t
   end.
Notation "'[' x ':=' s ']' t" := (subst x \ s \ t) (at level 20).
```

# 9.2 Pragmatics

# 9.2.1 Side Effects and Sequencing

The fact that the result of an assignment expression is the trivial value **unit** allows us to use a nice abbreviation for *sequencing*. For example, we can write

```
r:=succ(!r); !r
```

as an abbreviation for

```
(\x:Unit. !r) (r := succ(!r)).
```

This has the effect of evaluating two expressions in order and returning the value of the second. Restricting the type of the first expression to *Unit* helps the typechecker to catch some silly errors by permitting us to throw away the first value only if it is really guaranteed to be trivial.

Notice that, if the second expression is also an assignment, then the type of the whole sequence will be Unit, so we can validly place it to the left of another; to build longer sequences of assignments:

```
r:=succ(!r); r:=succ(!r); r:=succ(!r); !r
```

Formally, we introduce sequencing as a "derived form" tseq that expands into an abstraction and an application.

```
Definition tseq t1 t2 := tapp (tabs (Id 0) TUnit t2) t1.
```

## 9.2.2 References and Aliasing

It is important to bear in mind the difference between the *reference* that is bound to r and the *cell* in the store that is pointed to by this reference.

If we make a copy of r, for example by binding its value to another variable s, what gets copied is only the *reference*, not the contents of the cell itself.

For example, after evaluating

```
let r = ref 5 in
let s = r in
s := 82;
(!r)+1
```

the cell referenced by r will contain the value 82, while the result of the whole expression will be 83. The references r and s are said to be *aliases* for the same cell.

The possibility of aliasing can make programs with references quite tricky to reason about. For example, the expression

```
r := 5; r := !s
```

assigns 5 to r and then immediately overwrites it with s's current value; this has exactly the same effect as the single assignment

```
r := !s
```

unless we happen to do it in a context where r and s are aliases for the same cell!

### 9.2.3 Shared State

Of course, aliasing is also a large part of what makes references useful. In particular, it allows us to set up "implicit communication channels" – shared state – between different parts of a program. For example, suppose we define a reference cell and two functions that manipulate its contents:

```
let c = ref 0 in
let incc = \_:Unit. (c := succ (!c); !c) in
let decc = \_:Unit. (c := pred (!c); !c) in
```

Note that, since their argument types are *Unit*, the abstractions in the definitions of *incc* and *decc* are not providing any useful information to the bodies of the functions (using the wildcard \_ as the name of the bound variable is a reminder of this). Instead, their purpose is to "slow down" the execution of the function bodies: since function abstractions are values, the two lets are executed simply by binding these functions to the names *incc* and *decc*, rather than by actually incrementing or decrementing c. Later, each call to one of these functions results in its body being executed once and performing the appropriate mutation on c. Such functions are often called *thunks*.

In the context of these declarations, calling *incc* results in changes to c that can be observed by calling *decc*. For example, if we replace the ... with (*incc* unit; *incc* unit; *decc* unit), the result of the whole program will be 1.

## 9.2.4 Objects

We can go a step further and write a function that creates c, incc, and decc, packages incc and decc together into a record, and returns this record:

```
newcounter =
  \_:Unit.
  let c = ref 0 in
  let incc = \_:Unit. (c := succ (!c); !c) in
  let decc = \_:Unit. (c := pred (!c); !c) in
  {i=incc, d=decc}
```

Now, each time we call *newcounter*, we get a new record of functions that share access to the same storage cell **c**. The caller of *newcounter* can't get at this storage cell directly, but can affect it indirectly by calling the two functions. In other words, we've created a simple form of *object*.

```
let c1 = newcounter unit in
let c2 = newcounter unit in
// Note that we've allocated two separate storage cells now!
let r1 = c1.i unit in
let r2 = c2.i unit in
r2 // yields 1, not 2!
```

Exercise: 1 star (store\_draw) Draw (on paper) the contents of the store at the point in execution where the first two lets have finished and the third one is about to begin.

## 9.2.5 References to Compound Types

A reference cell need not contain just a number: the primitives we've defined above allow us to create references to values of any type, including functions. For example, we can use references to functions to give a (not very efficient) implementation of arrays of numbers, as follows. Write NatArray for the type  $Ref(Nat \rightarrow Nat)$ .

Recall the equal function from the MoreStlc chapter:

```
equal =
  fix
  (\eq:Nat->Nat->Bool.
  \m:Nat. \n:Nat.
    if m=0 then iszero n
    else if n=0 then false
    else eq (pred m) (pred n))
```

Now, to build a new array, we allocate a reference cell and fill it with a function that, when given an index, always returns 0.

```
newarray = \_:Unit. ref (\n:Nat.0)
```

To look up an element of an array, we simply apply the function to the desired index.

```
lookup = \a:NatArray. \n:Nat. (!a) n
```

The interesting part of the encoding is the update function. It takes an array, an index, and a new value to be stored at that index, and does its job by creating (and storing in the reference) a new function that, when it is asked for the value at this very index, returns the new value that was given to update, and on all other indices passes the lookup to the function that was previously stored in the reference.

```
update = \a:NatArray. \m:Nat. \v:Nat.
let oldf = !a in
a := (\n:Nat. if equal m n then v else oldf n);
```

References to values containing other references can also be very useful, allowing us to define data structures such as mutable lists and trees.

Exercise: 2 stars (compact\_update) If we defined update more compactly like this

would it behave the same?

#### 9.2.6 Null References

There is one more difference between our references and C-style mutable variables: in C-like languages, variables holding pointers into the heap may sometimes have the value *NULL*. Dereferencing such a "null pointer" is an error, and results in an exception (Java) or in termination of the program (C).

Null pointers cause significant trouble in C-like languages: the fact that any pointer might be null means that any dereference operation in the program can potentially fail. However, even in ML-like languages, there are occasionally situations where we may or may not have a valid pointer in our hands. Fortunately, there is no need to extend the basic mechanisms of references to achieve this: the sum types introduced in the MoreStlc chapter already give us what we need.

First, we can use sums to build an analog of the **option** types introduced in the Lists chapter. Define  $Option\ T$  to be an abbreviation for  $Unit\ +\ T$ .

Then a "nullable reference to a T" is simply an element of the type  $Option\ (Ref\ T)$ .

## 9.2.7 Garbage Collection

A last issue that we should mention before we move on with formalizing references is storage de-allocation. We have not provided any primitives for freeing reference cells when they are no longer needed. Instead, like many modern languages (including ML and Java) we rely on the run-time system to perform garbage collection, collecting and reusing cells that can no longer be reached by the program.

This is *not* just a question of taste in language design: it is extremely difficult to achieve type safety in the presence of an explicit deallocation operation. The reason for this is the familiar dangling reference problem: we allocate a cell holding a number, save a reference to it in some data structure, use it for a while, then deallocate it and allocate a new cell holding a boolean, possibly reusing the same storage. Now we can have two names for the same storage cell – one with type Ref Nat and the other with type Ref Bool.

Exercise: 1 star (type\_safety\_violation) Show how this can lead to a violation of type safety.

# 9.3 Operational Semantics

#### 9.3.1 Locations

The most subtle aspect of the treatment of references appears when we consider how to formalize their operational behavior. One way to see why is to ask, "What should be the values of type  $Ref\ T$ ?" The crucial observation that we need to take into account is that

evaluating a ref operator should do something – namely, allocate some storage – and the result of the operation should be a reference to this storage.

What, then, is a reference?

The run-time store in most programming language implementations is essentially just a big array of bytes. The run-time system keeps track of which parts of this array are currently in use; when we need to allocate a new reference cell, we allocate a large enough segment from the free region of the store (4 bytes for integer cells, 8 bytes for cells storing Floats, etc.), mark it as being used, and return the index (typically, a 32- or 64-bit integer) of the start of the newly allocated region. These indices are references.

For present purposes, there is no need to be quite so concrete. We can think of the store as an array of values, rather than an array of bytes, abstracting away from the different sizes of the run-time representations of different values. A reference, then, is simply an index into the store. (If we like, we can even abstract away from the fact that these indices are numbers, but for purposes of formalization in Coq it is a bit more convenient to use numbers.) We'll use the word location instead of reference or pointer from now on to emphasize this abstract quality.

Treating locations abstractly in this way will prevent us from modeling the *pointer arithmetic* found in low-level languages such as C. This limitation is intentional. While pointer arithmetic is occasionally very useful, especially for implementing low-level services such as garbage collectors, it cannot be tracked by most type systems: knowing that location n in the store contains a *float* doesn't tell us anything useful about the type of location n+4. In C, pointer arithmetic is a notorious source of type safety violations.

#### 9.3.2 Stores

Recall that, in the small-step operational semantics for IMP, the step relation needed to carry along an auxiliary state in addition to the program being executed. In the same way, once we have added reference cells to the STLC, our step relation must carry along a store to keep track of the contents of reference cells.

We could re-use the same functional representation we used for states in IMP, but for carrying out the proofs in this chapter it is actually more convenient to represent a store simply as a *list* of values. (The reason we couldn't use this representation before is that, in IMP, a program could modify any location at any time, so states had to be ready to map any variable to a value. However, in the STLC with references, the only way to create a reference cell is with tref t1, which puts the value of t1 in a new reference cell and evaluates to the location of the newly created reference cell. When evaluating such an expression, we can just add a new reference cell to the end of the list representing the store.)

Definition store := list tm.

We use store\_lookup n st to retrieve the value of the reference cell at location n in the store st. Note that we must give a default value to nth in case we try looking up an index which is too large. (In fact, we will never actually do this, but proving it will of course require some work!)

```
Definition store_lookup (n:nat) (st:store) :=
  nth n st tunit.
    To add a new reference cell to the store, we use snoc.
Fixpoint snoc \{A: \mathsf{Type}\}\ (l: \mathsf{list}\ A)\ (x:A): \mathsf{list}\ A :=
  match l with
  | \mathsf{nil} \Rightarrow x :: \mathsf{nil}
  |h::t\Rightarrow h::snoc\ t\ x
  end.
    We will need some boring lemmas about snoc. The proofs are routine inductions.
Lemma length_snoc : \forall A (l: list A) x,
  length (snoc l(x) = S (length l).
Proof.
  induction l; intros; [auto | simpl; rewrite IHl; auto ]. Qed.
Lemma nth_{lt\_snoc}: \forall A (l: list A) x d n,
  n < \text{length } l \rightarrow
  nth n l d = nth n (snoc l x) d.
  induction l as [|a|l']; intros; try solve by inversion.
  Case "l = a :: l'".
     destruct n; auto.
     simpl. apply IHl'.
     simpl in H. apply t_S_n in H. assumption.
Qed.
Lemma nth_{eq}-snoc : \forall A (l: list A) x d,
  nth (length l) (snoc l x) d = x.
Proof.
  induction l; intros; [ auto | simpl; rewrite IHl; auto ].
    To update the store, we use the replace function, which replaces the contents of a cell
at a particular index.
Fixpoint replace \{A: \mathsf{Type}\}\ (n:\mathsf{nat})\ (x:A)\ (l:\mathsf{list}\ A): \mathsf{list}\ A :=
  match l with
  | nil \Rightarrow nil
  |h::t\Rightarrow
    match n with
     | 0 \Rightarrow x :: t
     | S n' \Rightarrow h :: replace n' x t
     end
  end.
```

Of course, we also need some boring lemmas about replace, which are also fairly straightforward to prove.

```
Lemma replace_nil : \forall A \ n \ (x:A),
  replace n \times nil = nil.
Proof.
  destruct n; auto.
Qed.
Lemma length_replace : \forall A \ n \ x \ (l: list \ A),
  length (replace n \times l) = length l.
Proof with auto.
  intros A n x l. generalize dependent n.
  induction l; intros n.
     \operatorname{destruct} n...
     destruct n...
       simpl. rewrite IHl...
Qed.
Lemma lookup_replace_eq : \forall l t st,
  l < \text{length } st \rightarrow
  store_lookup l (replace l t st) = t.
Proof with auto.
  intros l t st.
  unfold store_lookup.
  generalize dependent l.
  induction st as [t' st']; intros l Hlen.
  Case "st = []".
   inversion Hlen.
  Case "st = t' :: st'".
     destruct l; simpl...
     apply IHst'. simpl in Hlen. omega.
Qed.
Lemma lookup_replace_neq : \forall l1 l2 t st,
  l1 \neq l2 \rightarrow
  store_lookup l1 (replace l2 t st) = store_lookup l1 st.
Proof with auto.
  unfold store_lookup.
  induction l1 as [|l1'|]; intros l2 t st Hneq.
  Case "11 = 0".
     destruct st.
     SCase "st = []". rewrite replace_nil...
     SCase "st = _:: _". destruct l2... contradict Hneq...
  Case "11 = S 11".
```

```
destruct st as [lt2 \ st2]. SCase "st = []". destruct l2... SCase "st = t2 :: st2". destruct l2... simpl; apply IHl1'... Qed.
```

### 9.3.3 Reduction

Next, we need to extend our operational semantics to take stores into account. Since the result of evaluating an expression will in general depend on the contents of the store in which it is evaluated, the evaluation rules should take not just a term but also a store as argument. Furthermore, since the evaluation of a term may cause side effects on the store that may affect the evaluation of other terms in the future, the evaluation rules need to return a new store. Thus, the shape of the single-step evaluation relation changes from t ==> t' to t / st ==> t' / st', where st and st' are the starting and ending states of the store.

To carry through this change, we first need to augment all of our existing evaluation rules with stores: value  $\mathbf{v}2$ 

```
 \begin{array}{l} {\rm (ST\_AppAbs)} \ (\x:T.t12) \ v2 \ / \ st ==> x:= v2t12 \ / \ st \\ {\rm t1 \ / \ st \ ==> t1' \ / \ st'} \\ {\rm (ST\_App1) \ t1 \ t2 \ / \ st \ ==> t1' \ t2 \ / \ st'} \\ {\rm value \ v1 \ t2 \ / \ st \ ==> t2' \ / \ st'} \\ \end{array}
```

(ST\_App2) v1 t2 / st ==> v1 t2' / st' Note that the first rule here returns the store unchanged: function application, in itself, has no side effects. The other two rules simply propagate side effects from premise to conclusion.

Now, the result of evaluating a *ref* expression will be a fresh location; this is why we included locations in the syntax of terms and in the set of values.

It is crucial to note that making this extension to the syntax of terms does not mean that we intend *programmers* to write terms involving explicit, concrete locations: such terms will arise only as intermediate results of evaluation. This may initially seem odd, but really it follows naturally from our design decision to represent the result of every evaluation step by a modified term. If we had chosen a more "machine-like" model for evaluation, e.g. with an explicit stack to contain values of bound identifiers, then the idea of adding locations to the set of allowed values would probably seem more obvious.

In terms of this expanded syntax, we can state evaluation rules for the new constructs that manipulate locations and the store. First, to evaluate a dereferencing expression !t1, we must first reduce t1 until it becomes a value: t1 / st ==> t1' / st'

(ST\_Deref) !t1 / st ==> !t1' / st' Once t1 has finished reducing, we should have an expression of the form !!, where ! is some location. (A term that attempts to dereference

any other sort of value, such as a function or **unit**, is erroneous, as is a term that tries to derefence a location that is larger than the size |st| of the currently allocated store; the evaluation rules simply get stuck in this case. The type safety properties that we'll establish below assure us that well-typed terms will never misbehave in this way.) 1 < |st|

```
(ST_DerefLoc) !(loc l) / st ==> lookup l st / st
```

Next, to evaluate an assignment expression t1:=t2, we must first evaluate t1 until it becomes a value (a location), and then evaluate t2 until it becomes a value (of any sort): t1 / st ==> t1' / st'

```
(ST_Assign1) t1 := t2 / st ==> t1' := t2 / st' t2 / st ==> t2' / st'
```

(ST\_Assign2) v1 := t2 / st ==> v1 := t2' / st' Once we have finished with t1 and t2, we have an expression of the form 1:=v2, which we execute by updating the store to make location 1 contain v2: 1 < |st|

(ST\_Assign) loc 1 := v2 / st ==> unit / !=v2st The notation [!=v2]st means "the store that maps I to v2 and maps all other locations to the same thing as st." Note that the term resulting from this evaluation step is just **unit**; the interesting result is the updated store.)

Finally, to evaluate an expression of the form  $ref\ t1$ , we first evaluate t1 until it becomes a value: t1 / st ==> t1' / st'

(ST\_Ref) ref t1 / st ==> ref t1' / st' Then, to evaluate the *ref* itself, we choose a fresh location at the end of the current store – i.e., location |st| – and yield a new store that extends st with the new value v1.

(ST\_RefValue) ref v1 / st ==> loc |st| / st,v1 The value resulting from this step is the newly allocated location itself. (Formally, st,v1 means snoc st v1.)

Note that these evaluation rules do not perform any kind of garbage collection: we simply allow the store to keep growing without bound as evaluation proceeds. This does not affect the correctness of the results of evaluation (after all, the definition of "garbage" is precisely parts of the store that are no longer reachable and so cannot play any further role in evaluation), but it means that a naive implementation of our evaluator might sometimes run out of memory where a more sophisticated evaluator would be able to continue by reusing locations whose contents have become garbage.

Formally...

# 9.4 Typing

Our contexts for free variables will be exactly the same as for the STLC, partial maps from identifiers to types.

Definition context := partial\_map ty.

## 9.4.1 Store typings

Having extended our syntax and evaluation rules to accommodate references, our last job is to write down typing rules for the new constructs – and, of course, to check that they are sound. Naturally, the key question is, "What is the type of a location?"

First of all, notice that we do *not* need to answer this question for purposes of type-checking the terms that programmers actually write. Concrete location constants arise only in terms that are the intermediate results of evaluation; they are not in the language that programmers write. So we only need to determine the type of a location when we're in the middle of an evaluation sequence, e.g. trying to apply the progress or preservation lemmas. Thus, even though we normally think of typing as a *static* program property, it makes sense for the typing of locations to depend on the *dynamic* progress of the program too.

As a first try, note that when we evaluate a term containing concrete locations, the type of the result depends on the contents of the store that we start with. For example, if we evaluate the term  $!(loc\ 1)$  in the store [unit, unit], the result is unit; if we evaluate the same term in the store [unit, x:Unit.x], the result is x:Unit.x. With respect to the former store, the location 1 has type Unit, and with respect to the latter it has type  $Unit \rightarrow Unit$ . This observation leads us immediately to a first attempt at a typing rule for locations: Gamma |- lookup l st : T1

Gamma  $\mid$ - loc l : Ref T1 That is, to find the type of a location I, we look up the current contents of I in the store and calculate the type T1 of the contents. The type of the location is then  $Ref\ T1$ .

Having begun in this way, we need to go a little further to reach a consistent state. In effect, by making the type of a term depend on the store, we have changed the typing relation from a three-place relation (between contexts, terms, and types) to a four-place relation (between contexts, stores, terms, and types). Since the store is, intuitively, part of the context in which we calculate the type of a term, let's write this four-place relation with the store to the left of the turnstile: Gamma;  $st \vdash t$ : T. Our rule for typing references now has the form Gamma;  $st \vdash l$  lookup l st: l

Gamma; st |- loc l : Ref T1 and all the rest of the typing rules in the system are extended similarly with stores. The other rules do not need to do anything interesting with their stores – just pass them from premise to conclusion.

However, there are two problems with this rule. First, typechecking is rather inefficient, since calculating the type of a location I involves calculating the type of the current contents v of I. If I appears many times in a term t, we will re-calculate the type of v many times in the course of constructing a typing derivation for t. Worse, if v itself contains locations, then we will have to recalculate their types each time they appear.

Second, the proposed typing rule for locations may not allow us to derive anything at all, if the store contains a *cycle*. For example, there is no finite typing derivation for the location 0 with respect to this store:

```
[x:Nat. (!(loc 1)) x, x:Nat. (!(loc 0)) x]
```

Exercise: 2 stars (cyclic\_store) Can you find a term whose evaluation will create this particular cyclic store?

Both of these problems arise from the fact that our proposed typing rule for locations requires us to recalculate the type of a location every time we mention it in a term. But this, intuitively, should not be necessary. After all, when a location is first created, we know the type of the initial value that we are storing into it. Suppose we are willing to enforce the invariant that the type of the value contained in a given location never changes; that is, although we may later store other values into this location, those other values will always have the same type as the initial one. In other words, we always have in mind a single, definite type for every location in the store, which is fixed when the location is allocated. Then these intended types can be collected together as a store typing —a finite function mapping locations to types.

As usual, this *conservative* typing restriction on allowed updates means that we will rule out as ill-typed some programs that could evaluate perfectly well without getting stuck.

Just like we did for stores, we will represent a store type simply as a list of types: the type at index i records the type of the value stored in cell i.

```
Definition store_ty := list ty.
```

The store\_Tlookup function retrieves the type at a particular index.

```
Definition store_Tlookup (n:nat) (ST:store_ty) := nth \ n \ ST TUnit.
```

Suppose we are given a store typing ST describing the store st in which some term t will be evaluated. Then we can use ST to calculate the type of the result of t without ever looking directly at st. For example, if ST is  $[Unit, Unit \rightarrow Unit]$ , then we may immediately infer that  $!(loc\ 1)$  has type  $Unit \rightarrow Unit$ . More generally, the typing rule for locations can be reformulated in terms of store typings like this: 1 < |ST|

```
Gamma; ST |- loc l : Ref (lookup l ST)
```

That is, as long as I is a valid location (it is less than the length of ST), we can compute the type of I just by looking it up in ST. Typing is again a four-place relation, but it is parameterized on a store typing rather than a concrete store. The rest of the typing rules are analogously augmented with store typings.

# 9.4.2 The Typing Relation

We can now give the typing relation for the STLC with references. Here, again, are the rules we're adding to the base STLC (with numbers and *Unit*):

```
l < |ST|
```

```
(T_Loc) Gamma; ST \mid- loc l : Ref (lookup l ST) Gamma; ST \mid- t1 : T1
```

```
(T_Ref) Gamma; ST |- ref t1 : Ref T1
     Gamma; ST |- t1 : Ref T11
 (T_Deref) Gamma; ST |-!t1: T11
     Gamma; ST |- t1 : Ref T11 Gamma; ST |- t2 : T11
 (T_Assign) Gamma; ST \mid -t1 := t2 : Unit
Reserved Notation "Gamma '; ST '-' t '\in' T" (at level 40).
Inductive has\_type: context \rightarrow store_ty \rightarrow tm \rightarrow ty \rightarrow Prop :=
   | T_{\text{Var}} : \forall Gamma \ ST \ x \ T,
          Gamma \ x = Some \ T \rightarrow
          Gamma; ST \vdash (tvar x) \setminus in T
   | \mathsf{T}_{-}\mathsf{Abs} : \forall \ Gamma \ ST \ x \ T11 \ T12 \ t12,
          (extend Gamma \ x \ T11); ST \vdash t12 \setminus in \ T12 \rightarrow
          Gamma; ST \vdash (tabs x T11 t12) \setminus in (TArrow T11 T12)
   \mid \mathsf{T}_{-}\mathsf{App} : \forall T1 \ T2 \ Gamma \ ST \ t1 \ t2,
          Gamma; ST \vdash t1 \setminus in (TArrow T1 T2) \rightarrow

```

Of course, these typing rules will accurately predict the results of evaluation only if the concrete store used during evaluation actually conforms to the store typing that we assume for purposes of typechecking. This proviso exactly parallels the situation with free variables in the STLC: the substitution lemma promises us that, if  $Gamma \vdash t : T$ , then we can replace the free variables in t with values of the types listed in Gamma to obtain a closed term of type T, which, by the type preservation theorem will evaluate to a final result of type T if it yields any result at all. (We will see later how to formalize an analogous intuition for stores and store typings.)

However, for purposes of typechecking the terms that programmers actually write, we do not need to do anything tricky to guess what store typing we should use. Recall that concrete location constants arise only in terms that are the intermediate results of evaluation; they are not in the language that programmers write. Thus, we can simply typecheck the programmer's terms with respect to the *empty* store typing. As evaluation proceeds and new locations are created, we will always be able to see how to extend the store typing by looking at the type of the initial values being placed in newly allocated cells; this intuition is formalized in the statement of the type preservation theorem below.

# 9.5 Properties

Our final task is to check that standard type safety properties continue to hold for the STLC with references. The progress theorem ("well-typed terms are not stuck") can be stated and proved almost as for the STLC; we just need to add a few straightforward cases to the proof, dealing with the new constructs. The preservation theorem is a bit more interesting, so let's look at it first.

# 9.5.1 Well-Typed Stores

Since we have extended both the evaluation relation (with initial and final stores) and the typing relation (with a store typing), we need to change the statement of preservation to include these parameters. Clearly, though, we cannot just add stores and store typings without saying anything about how they are related:

```
Theorem preservation_wrong1 : \forall ST T t st t' st', empty; ST \vdash t \setminus in T \rightarrow t / st ==> t' / st' \rightarrow empty; ST \vdash t' \setminus in T.
Abort.
```

If we typecheck with respect to some set of assumptions about the types of the values in the store and then evaluate with respect to a store that violates these assumptions, the result will be disaster. We say that a store st is  $well\ typed$  with respect a store typing ST if the term at each location I in st has the type at location I in st. Since only closed terms ever get stored in locations (why?), it suffices to type them in the empty context. The following definition of  $store\_well\_typed$  formalizes this.

```
Definition store_well_typed (ST: \mathsf{store\_ty}) (st: \mathsf{store}) := \mathsf{length} \ ST = \mathsf{length} \ st \land (\forall \ l, \ l < \mathsf{length} \ st \rightarrow \mathsf{empty}; \ ST \vdash (\mathsf{store\_lookup} \ l \ st) \setminus \mathsf{in} \ (\mathsf{store\_Tlookup} \ l \ ST)). Informally, we will write ST \vdash st for \mathsf{store\_well\_typed} \ ST \ st.
```

Intuitively, a store st is consistent with a store typing ST if every value in the store has the type predicted by the store typing. (The only subtle point is the fact that, when typing the values in the store, we supply the very same store typing to the typing relation! This allows us to type circular stores.)

Exercise: 2 stars (store\_not\_unique) Can you find a store st, and two different store typings ST1 and ST2 such that both  $ST1 \vdash st$  and  $ST2 \vdash st$ ?

We can now state something closer to the desired preservation property:

```
Theorem preservation_wrong2 : \forall ST \ T \ t \ st \ t' \ st', empty; ST \vdash t \setminus in \ T \rightarrow
```

```
t / st ==> t' / st' \rightarrow store_well_typed ST st \rightarrow empty; ST \vdash t' \in T. Abort.
```

This statement is fine for all of the evaluation rules except the allocation rule  $ST_RefValue$ . The problem is that this rule yields a store with a larger domain than the initial store, which falsifies the conclusion of the above statement: if st' includes a binding for a fresh location I, then I cannot be in the domain of ST, and it will not be the case that t' (which definitely mentions I) is typable under ST.

## 9.5.2 Extending Store Typings

Evidently, since the store can increase in size during evaluation, we need to allow the store typing to grow as well. This motivates the following definition. We say that the store type ST' extends ST if ST' is just ST with some new types added to the end.

```
\begin{array}{l} \textbf{Inductive extends}: \textbf{store\_ty} \rightarrow \textbf{store\_ty} \rightarrow \textbf{Prop} := \\ | \ \textbf{extends\_nil} : \forall \ ST', \\ \textbf{extends} \ ST' \ \textbf{nil} \\ | \ \textbf{extends\_cons} : \forall \ x \ ST' \ ST, \\ \textbf{extends} \ ST' \ ST \rightarrow \\ \textbf{extends} \ (x :: ST') \ (x :: ST). \end{array}
```

Hint Constructors extends.

We'll need a few technical lemmas about extended contexts.

First, looking up a type in an extended store typing yields the same result as in the original:

```
Lemma extends_lookup : \forall l ST ST',
  l < length ST \rightarrow
  extends ST' ST \rightarrow
  store\_Tlookup\ l\ ST' = store\_Tlookup\ l\ ST.
Proof with auto.
  intros l ST ST' Hlen H.
  generalize dependent ST'. generalize dependent l.
  induction ST as [a ST2]; intros l Hlen ST' HST'.
  Case "nil". inversion Hlen.
  Case "cons". unfold store_Tlookup in *.
    destruct ST'.
    SCase "ST' = nil". inversion HST'.
    SCase "ST' = a' :: ST'2".
      inversion HST'; subst.
      destruct l as [|l'|].
      SSCase "l = 0"...
```

```
SSCase "l = S l'". simpl. apply IHST2...
          simpl in Hlen; omega.
Qed.
   Next, if ST' extends ST, the length of ST' is at least that of ST.
Lemma length_extends : \forall l ST ST',
  l < \text{length } ST \rightarrow
  extends ST' ST \rightarrow
  l < length ST'.
Proof with eauto.
  intros. generalize dependent l. induction H0; intros l Hlen.
     inversion Hlen.
     simpl in *.
     destruct l; try omega.
       apply <a href="mailto:ltm.s.">lt_n_S</a>. apply <a href="mailto:ltm.s.">IHextends</a>. omega.
Qed.
   Finally, snoc ST T extends ST, and extends is reflexive.
Lemma extends_snoc : \forall ST T,
  extends (snoc ST T) ST.
Proof with auto.
  induction ST; intros T...
  simpl...
Qed.
Lemma extends_refl : \forall ST,
  extends ST ST.
Proof.
  induction ST; auto.
Qed.
```

# 9.5.3 Preservation, Finally

We can now give the final, correct statement of the type preservation property:

```
Definition preservation_theorem := \forall \ ST \ t \ t' \ T \ st \ st', empty; ST \vdash t \setminus \text{in } T \rightarrow store_well_typed ST \ st \rightarrow t \ / \ st ==> t' \ / \ st' \rightarrow \exists \ ST', (extends ST' \ ST \land empty; ST' \vdash t' \setminus \text{in } T \land store_well_typed ST' \ st').
```

Note that the preservation theorem merely asserts that there is *some* store typing ST' extending ST (i.e., agreeing with ST on the values of all the old locations) such that the

new term t' is well typed with respect to ST'; it does not tell us exactly what ST' is. It is intuitively clear, of course, that ST' is either ST or else it is exactly snoc ST T1, where T1 is the type of the value v1 in the extended store snoc st v1, but stating this explicitly would complicate the statement of the theorem without actually making it any more useful: the weaker version above is already in the right form (because its conclusion implies its hypothesis) to "turn the crank" repeatedly and conclude that every sequence of evaluation steps preserves well-typedness. Combining this with the progress property, we obtain the usual guarantee that "well-typed programs never go wrong."

In order to prove this, we'll need a few lemmas, as usual.

#### 9.5.4 Substitution lemma

First, we need an easy extension of the standard substitution lemma, along with the same machinery about context invariance that we used in the proof of the substitution lemma for the STLC.

```
Inductive appears_free_in : id \rightarrow tm \rightarrow Prop :=
    afi_var: \forall x,
        appears_free_in x (tvar x)
  | afi_app1 : \forall x t1 t2,
        appears_free_in x t1 \rightarrow appears_free_in x (tapp t1 t2)
  | afi_app2 : \forall x t1 t2,
        appears_free_in x \ t2 \rightarrow appears_free_in \ x \ (tapp \ t1 \ t2)
  | afi_abs : \forall x y T11 t12,
        y \neq x \rightarrow
        appears_free_in x t12 \rightarrow
        appears_free_in x (tabs y T11 t12)
  | afi_succ : \forall x t1,
        appears_free_in x t1 \rightarrow
        appears_free_in x (tsucc t1)
  | afi_pred : \forall x t1,
        appears_free_in x t1 \rightarrow
        appears_free_in x (tpred t1)
  | afi_mult1 : \forall x t1 t2,
        appears_free_in x t1 \rightarrow
        appears_free_in x (tmult t1 t2)
  | afi_mult2 : \forall x t1 t2,
        appears_free_in x t2 \rightarrow
        appears_free_in x (tmult t1 t2)
  | afi_if0_1: \forall x t1 t2 t3,

# 9.5.5 Assignment Preserves Store Typing

Next, we must show that replacing the contents of a cell in the store with a new value of appropriate type does not change the overall type of the store. (This is needed for the  $\mathsf{ST}_{-}\mathsf{Assign}$  rule.)

```
Lemma assign_pres_store_typing : \forall ST \ st \ l \ t, l < length \ st \rightarrow store_well_typed ST \ st \rightarrow empty; ST \vdash t \setminus in \ (store\_Tlookup \ l \ ST) \rightarrow store_well_typed ST \ (replace \ l \ t \ st). Proof with auto. intros ST \ st \ l \ t \ Hlen \ HST \ Ht. inversion HST; subst. split. rewrite length_replace... intros l' \ Hl'. destruct (beq_nat l' \ l) \ eqn: Heqll'. ```

```
rewrite lookup_replace_eq... Case \ "l' <> l". apply \ beq\_nat\_false \ in \ Heqll'. rewrite \ lookup\_replace\_neq... rewrite \ length\_replace \ in \ Hl'. apply \ H0... Qed.
```

# 9.5.6 Weakening for Stores

Finally, we need a lemma on store typings, stating that, if a store typing is extended with a new location, the extended one still allows us to assign the same types to the same terms as the original.

(The lemma is called **store\_weakening** because it resembles the "weakening" lemmas found in proof theory, which show that adding a new assumption to some logical theory does not decrease the set of provable theorems.)

```
Lemma store_weakening : \forall \ Gamma \ ST \ ST' \ t \ T, extends ST' \ ST \rightarrow Gamma; \ ST \vdash t \setminus in \ T \rightarrow Gamma; \ ST' \vdash t \setminus in \ T.

Proof with eauto.

intros. has\_type\_cases (induction H0) Case; eauto. Case "T_Loc".

erewrite \leftarrow \text{extends\_lookup...}

apply T_Loc.

eapply length_extends...

Qed.
```

We can use the store\_weakening lemma to prove that if a store is well typed with respect to a store typing, then the store extended with a new term t will still be well typed with respect to the store typing extended with t's type.

```
Lemma store_well_typed_snoc : \forall ST \ st \ t1 \ T1, store_well_typed ST \ st \rightarrow empty; ST \vdash t1 \setminus in \ T1 \rightarrow store_well_typed (snoc ST \ T1) (snoc st \ t1). Proof with auto. intros. unfold store_well_typed in *. inversion H as [Hlen \ Hmatch]; clear H. rewrite !length_snoc. split... Case "types match.". intros l \ Hl.
```

```
unfold store_lookup, store_Tlookup.

apply le_lt_eq_dec in Hl; inversion Hl as [Hlt \mid Heq].

## 9.6 References and Nontermination

Section RefsAndNontermination.

Import Example Variables.

We know that the simply typed lambda calculus is *normalizing*, that is, every well-typed term can be reduced to a value in a finite number of steps. What about STLC + references? Surprisingly, adding references causes us to lose the normalization property: there exist well-typed terms in the STLC + references which can continue to reduce forever, without ever reaching a normal form!

How can we construct such a term? The main idea is to make a function which calls itself. We first make a function which calls another function stored in a reference cell; the trick is that we then smuggle in a reference to itself!

```
(\r:Ref (Unit -> Unit).
    r := (\x:Unit.(!r) unit); (!r) unit)
(ref (\x:Unit.unit))
```

First, ref (\x: Unit.unit) creates a reference to a cell of type  $Unit \to Unit$ . We then pass this reference as the argument to a function which binds it to the name r, and assigns to it the function (\x:Unit.(!r) unit) – that is, the function which ignores its argument and calls the function stored in r on the argument **unit**; but of course, that function is itself! To get the ball rolling we finally execute this function with (!r) **unit**.

```
Definition loop_fun :=
  tabs \times TUnit (tapp (tderef (tvar r)) tunit).
Definition loop :=
  tapp
  (tabs r (TRef (TArrow TUnit TUnit))
     (tseq (tassign (tvar r) loop_fun)
               (tapp (tderef (tvar r)) tunit)))
  (tref (tabs \times TUnit tunit)).
   This term is well typed:
Lemma loop_typeable : \exists T, empty; \mathsf{nil} \vdash \mathsf{loop} \setminus \mathsf{in} T.
Proof with eauto.
  eexists. unfold loop. unfold loop_fun.
  eapply T_App...
  eapply T_Abs...
  eapply T_App...
     eapply T_Abs. eapply T_App. eapply T_Deref. eapply T_Var.
```

```
unfold extend. simpl. reflexivity. auto.
eapply T_Assign.
eapply T_Var. unfold extend. simpl. reflexivity.
eapply T_Abs.
eapply T_App...
eapply T_Deref. eapply T_Var. reflexivity.

Qed.
```

To show formally that the term diverges, we first define the **step\_closure** of the single-step reduction relation, written ==>+. This is just like the reflexive step closure of single-step reduction (which we're been writing ==>\*), except that it is not reflexive: t==>+t' means that t can reach t' by one or more steps of reduction.

```
Inductive step\_closure \{X:Type\}\ (R: relation \ X): X \to X \to Prop:= | sc\_one: \forall (x \ y : X), R \ x \ y \to step\_closure \ R \ x \ y | sc\_step: \forall (x \ y \ z : X), R \ x \ y \to step\_closure \ R \ y \ z \to step\_closure \ R \ x \ z.
Definition multistep1:= (step\_closure step).
Notation "t1'/' st'==>+' t2'/' st'":= (multistep1 (t1,st) (t2,st')) (at level 40, st at level 39, t2 at level 39).
```

Now, we can show that the expression loop reduces to the expression  $!(loc\ 0)$  unit and the size-one store  $[r:=(loc\ 0)]$  loop\_fun.

As a convenience, we introduce a slight variant of the *normalize* tactic, called *reduce*, which tries solving the goal with multi\_refl at each step, instead of waiting until the goal can't be reduced any more. Of course, the whole point is that loop doesn't normalize, so the old *normalize* tactic would just go into an infinite loop reducing it forever!

Finally, the latter expression reduces in two steps to itself!

```
Lemma loop_fun_step_self :
  tapp (tderef (tloc 0)) tunit / cons ([r:=tloc 0]loop_fun) nil ==>+
  tapp (tderef (tloc 0)) tunit / cons ([r:=tloc 0]loop_fun) nil.
Proof with eauto.
  unfold loop_fun; simpl.
  eapply sc_step. apply ST_App1...
  eapply sc_one. compute. apply ST_AppAbs...
Qed.
```

Exercise: 4 stars (factorial\_ref) Use the above ideas to implement a factorial function in STLC with references. (There is no need to prove formally that it really behaves like the factorial. Just use the example below to make sure it gives the correct result when applied to the argument 4.)

```
Definition factorial: tm :=
   admit.
Lemma factorial_type : empty; nil ⊢ factorial \in (TArrow TNat TNat).
Proof with eauto.
   Admitted.
```

If your definition is correct, you should be able to just uncomment the example below; the proof should be fully automatic using the *reduce* tactic.

# 9.7 Additional Exercises

Exercise: 5 stars, optional (garabage\_collector) Challenge problem: modify our formalization to include an account of garbage collection, and prove that it satisfies whatever nice properties you can think to prove about it.

End RefsAndNontermination.

End STLCREF.

# Chapter 10

# Library Records

## 10.1 Records: Adding Records to STLC

Require Export Stlc.

## 10.2 Adding Records

Reduction: ti ==> ti' (ST\_Rcd)

We saw in chapter MoreStlc how records can be treated as syntactic sugar for nested uses of products. This is fine for simple examples, but the encoding is informal (in reality, if we really treated records this way, it would be carried out in the parser, which we are eliding here), and anyway it is not very efficient. So it is also interesting to see how records can be treated as first-class citizens of the language.

Recall the informal definitions we gave before:

Syntax:

```
{i1=v1, ..., im=vm, in=tn, ...} ==> {i1=v1, ..., im=vm, in=tn', ...}

t1 ==> t1'

(ST_Proj1) t1.i ==> t1'.i

(ST_ProjRcd) {..., i=vi, ...}.i ==> vi Typing: Gamma |- t1 : T1 ... Gamma |- tn : Tn

(T_Rcd) Gamma |- {i1=t1, ..., in=tn} : {i1:T1, ..., in:Tn}

Gamma |- t : {..., i:Ti, ...}

(T_Proj) Gamma |- t.i : Ti
```

## 10.3 Formalizing Records

Module STLCEXTENDEDRECORDS.

### Syntax and Operational Semantics

The most obvious way to formalize the syntax of record types would be this:

Module FIRSTTRY.

```
\begin{array}{l} \texttt{Definition alist} \; (X : \texttt{Type}) := \textbf{list} \; (\textbf{id} \times X). \\ \\ \texttt{Inductive ty} : \; \texttt{Type} := \\ | \; \texttt{TBase} : \; \textbf{id} \to \textbf{ty} \\ | \; \texttt{TArrow} : \; \textbf{ty} \to \textbf{ty} \to \textbf{ty} \\ | \; \texttt{TRcd} : \; (\texttt{alist ty}) \to \textbf{ty}. \end{array}
```

Unfortunately, we encounter here a limitation in Coq: this type does not automatically give us the induction principle we expect the induction hypothesis in the TRcd case doesn't give us any information about the **ty** elements of the list, making it useless for the proofs we want to do.

End FIRSTTRY.

It is possible to get a better induction principle out of Coq, but the details of how this is done are not very pretty, and it is not as intuitive to use as the ones Coq generates automatically for simple Inductive definitions.

Fortunately, there is a different way of formalizing records that is, in some ways, even simpler and more natural: instead of using the existing **list** type, we can essentially include its constructors ("nil" and "cons") in the syntax of types.

```
\begin{array}{l} \texttt{Inductive } \ \textbf{ty} : \texttt{Type} := \\ | \ \mathsf{TBase} : \ \textbf{id} \rightarrow \textbf{ty} \\ | \ \mathsf{TArrow} : \ \textbf{ty} \rightarrow \textbf{ty} \rightarrow \textbf{ty} \\ | \ \mathsf{TRNil} : \ \textbf{ty} \end{array}
```

```
| TRCons : id \rightarrow ty \rightarrow ty \rightarrow ty.
Tactic Notation "T_cases" tactic(first) ident(c) :=
  first:
  [ Case_aux c "TBase" | Case_aux c "TArrow"
   | Case_aux c "TRNil" | Case_aux c "TRCons" ].
    Similarly, at the level of terms, we have constructors trnil the empty record – and trcons,
which adds a single field to the front of a list of fields.
Inductive tm : Type :=
    \mathsf{tvar}:\mathsf{id}\to\mathsf{tm}
    \mathsf{tapp}: \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}
   \mid \mathsf{tabs} : \mathsf{id} 	o \mathsf{ty} 	o \mathsf{tm} 	o \mathsf{tm}
   tproj : \mathsf{tm} \to \mathsf{id} \to \mathsf{tm}
    trnil: tm
   | trcons : id \rightarrow tm \rightarrow tm \rightarrow tm.
Tactic Notation "t_cases" tactic(first) ident(c) :=
    Case_aux c "tvar" | Case_aux c "tapp" | Case_aux c "tabs"
    Case_aux c "tproj" | Case_aux c "trnil" | Case_aux c "trcons" ].
    Some variables, for examples...
Notation a := (Id \ 0).
```

```
Notation f := (Id \ 1).

Notation g := (Id \ 2).

Notation I := (Id \ 3).

Notation A := (TBase \ (Id \ 4)).

Notation B := (TBase \ (Id \ 5)).

Notation k := (Id \ 6).

Notation i1 := (Id \ 7).

Notation i2 := (Id \ 8).

\{ i1:A \rightarrow B, i2:A \}
```

#### Well-Formedness

Generalizing our abstract syntax for records (from lists to the nil/cons presentation) introduces the possibility of writing strange types like this

```
Definition weird_type := TRCons X A B.
```

where the "tail" of a record type is not actually a record type!

We'll structure our typing judgement so that no ill-formed types like weird\_type are assigned to terms. To support this, we define record\_ty and record\_tm, which identify record types and terms, and well\_formed\_ty which rules out the ill-formed types.

First, a type is a record type if it is built with just TRNil and TRCons at the outermost level.

```
Inductive record_ty: ty \rightarrow Prop := |RTnil : record_ty TRNil : record_ty TRNil |RTcons: <math>\forall i \ T1 \ T2, record_ty \ (TRCons \ i \ T1 \ T2).
Similarly, a term is a record term if it is built with trnil and trcons Inductive record_tm: tm \rightarrow Prop := |rtnil : record_tm \ trnil |rtcons: <math>\forall i \ t1 \ t2, record_tm \ (trcons \ i \ t1 \ t2).
```

Note that **record\_ty** and **record\_tm** are not recursive – they just check the outermost constructor. The **well\_formed\_ty** property, on the other hand, verifies that the whole type is well formed in the sense that the tail of every record (the second argument to TRCons) is a record.

Of course, we should also be concerned about ill-formed terms, not just types; but type-checking can rules those out without the help of an extra  $well\_formed\_tm$  definition because it already examines the structure of terms. LATER: should they fill in part of this as an exercise? We didn't give rules for it above

```
\begin{array}{l} \text{Inductive well\_formed\_ty}: \ \mathbf{ty} \rightarrow \texttt{Prop} := \\ | \ \mathsf{wfTBase} : \ \forall \ i, \\ & \ \mathsf{well\_formed\_ty} \ (\texttt{TBase} \ i) \\ | \ \mathsf{wfTArrow} : \ \forall \ T1 \ T2, \\ & \ \mathsf{well\_formed\_ty} \ T1 \rightarrow \\ & \ \mathsf{well\_formed\_ty} \ T2 \rightarrow \\ & \ \mathsf{well\_formed\_ty} \ (\texttt{TArrow} \ T1 \ T2) \\ | \ \mathsf{wfTRNil} : \\ & \ \mathsf{well\_formed\_ty} \ \texttt{TRNil} \\ | \ \mathsf{wfTRCons} : \ \forall \ i \ T1 \ T2, \\ & \ \mathsf{well\_formed\_ty} \ T1 \rightarrow \\ & \ \mathsf{well\_formed\_ty} \ T2 \rightarrow \\ & \ \mathsf{record\_ty} \ T2 \rightarrow \\ & \ \mathsf{vell\_formed\_ty} \ (\texttt{TRCons} \ i \ T1 \ T2). \\ \end{array}
```

Hint Constructors record\_ty record\_tm well\_formed\_ty.

### Substitution

```
Fixpoint subst (x:id) (s:tm) (t:tm) : tm :=
  match t with
    tvar y \Rightarrow if eq_id_dec x y then s else t
   tabs y \ T \ t1 \Rightarrow \text{tabs } y \ T \ (\text{if eq\_id\_dec} \ x \ y \ \text{then} \ t1 \ \text{else} \ (\text{subst} \ x \ s \ t1))
    tapp t1 t2 \Rightarrow \text{tapp (subst } x \ s \ t1) \ (\text{subst } x \ s \ t2)
    tproj t1 \ i \Rightarrow tproj (subst \ x \ s \ t1) \ i
   trnil \Rightarrow trnil
   | trcons i \ t1 \ tr1 \Rightarrow trcons i \ (subst \ x \ s \ t1) \ (subst \ x \ s \ tr1)
Notation "'[' x ':=' s ']' t" := (subst x \ s \ t) (at level 20).
Reduction
Next we define the values of our language. A record is a value if all of its fields are.
Inductive value : tm \rightarrow Prop :=
  | v_abs : \forall x T11 t12,
        value (tabs x T11 t12)
   | v_rnil : value trnil
  | v_{rcons} : \forall i v1 vr,
        value v1 \rightarrow
        value vr \rightarrow
        value (troons i \ v1 \ vr).
Hint Constructors value.
    Utility functions for extracting one field from record type or term:
Fixpoint Tlookup (i:id) (Tr:ty) : option ty :=
  match Tr with
    TRCons i' T Tr' \Rightarrow if eq_id_dec i i' then Some T else Tlookup i Tr'
   | \_ \Rightarrow \mathsf{None}
  end.
Fixpoint tlookup (i:id) (tr:tm) : option tm :=
  match \ tr \ with
   | troons i' t tr' \Rightarrow if eq_id_dec i i' then Some t else thookup i tr'
  | \_ \Rightarrow \mathsf{None}
  end.
    The step function uses the term-level lookup function (for the projection rule), while the
type-level lookup is needed for has_type.
Reserved Notation "t1'==>'t2" (at level 40).
```

Inductive step :  $tm \rightarrow tm \rightarrow Prop :=$ 

```
| ST_AppAbs : \forall x T11 t12 v2,
           value v2 \rightarrow
            (tapp (tabs x \ T11 \ t12) \ v2) ==> ([x := v2] t12)
  | ST\_App1 : \forall t1 t1' t2,
           t1 ==> t1' \rightarrow
            (tapp t1 t2) ==> (tapp t1' t2)
  | ST\_App2 : \forall v1 \ t2 \ t2',
           value v1 \rightarrow
           t2 ==> t2' \rightarrow
            (tapp v1 t2) ==> (tapp v1 t2')
  | ST_Proj1 : \forall t1 \ t1' \ i,
          t1 ==> t1' \rightarrow
          (tproj t1 i) ==> (tproj t1' i)
  | ST_ProjRcd : \forall tr i vi,
          value tr \rightarrow
          tlookup i \ tr = Some \ vi \rightarrow
          (tproj tr i) ==> vi
  | ST_Rcd_Head : \forall i t1 t1' tr2,
          t1 ==> t1' \rightarrow
          (trcons i \ t1 \ tr2) ==> (trcons i \ t1' \ tr2)
  | ST_Rcd_Tail : \forall i \ v1 \ tr2 \ tr2',
          value v1 \rightarrow
          tr2 ==> tr2' \rightarrow
          (trcons i \ v1 \ tr2) ==> (trcons i \ v1 \ tr2')
where "t1 '==>' t2" := (step t1 \ t2).
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first;
    Case_aux c "ST_AppAbs" | Case_aux c "ST_App1" | Case_aux c "ST_App2"
    Case_aux c "ST_Proj1" | Case_aux c "ST_ProjRcd"
    Case_aux c "ST_Rcd_Head" | Case_aux c "ST_Rcd_Tail" ].
Notation multistep := (multi step).
Notation "t1'==>*' t2" := (multistep t1 t2) (at level 40).
Hint Constructors step.
```

### **Typing**

Definition context := partial\_map ty.

Next we define the typing rules. These are nearly direct transcriptions of the inference rules shown above. The only major difference is the use of **well\_formed\_ty**. In the informal presentation we used a grammar that only allowed well formed record types, so we didn't have to add a separate check.

We'd like to set things up so that that whenever **has\_type** Gamma t T holds, we also have **well\_formed\_ty** T. That is, **has\_type** never assigns ill-formed types to terms. In fact, we prove this theorem below.

However, we don't want to clutter the definition of has\_type with unnecessary uses of well\_formed\_ty. Instead, we place well\_formed\_ty checks only where needed - where an inductive call to has\_type won't already be checking the well-formedness of a type.

For example, we check **well\_formed\_ty** T in the T\_Var case, because there is no inductive **has\_type** call that would enforce this. Similarly, in the T\_Abs case, we require a proof of **well\_formed\_ty** T11 because the inductive call to **has\_type** only guarantees that T12 is well-formed.

In the rules you must write, the only necessary **well\_formed\_ty** check comes in the **tnil** case.

```
Reserved Notation "Gamma '|-' t '\in' T" (at level 40).
Inductive has\_type: context \rightarrow tm \rightarrow ty \rightarrow Prop :=
        | T_{Var} : \forall Gamma \ x \ T,
                          Gamma \ x = Some \ T \rightarrow
                        well_formed_ty T \rightarrow
                          Gamma \vdash (\mathsf{tvar}\ x) \setminus \mathsf{in}\ T
        \mid \mathsf{T\_Abs} : \forall \ Gamma \ x \ T11 \ T12 \ t12,
                        well_formed_ty T11 \rightarrow
                          (extend Gamma \ x \ T11) \vdash t12 \setminus in \ T12 \rightarrow
                          Gamma \vdash (tabs \ x \ T11 \ t12) \setminus in (TArrow \ T11 \ T12)
        \mid \mathsf{T}_{-}\mathsf{App} : \forall T1 \ T2 \ Gamma \ t1 \ t2,
                          Gamma \vdash t1 \setminus in (TArrow T1 T2) \rightarrow
                          Gamma \vdash t2 \setminus in T1 \rightarrow
                          Gamma \vdash (tapp \ t1 \ t2) \setminus in \ T2
        | T_{-}Proj : \forall Gamma \ i \ t \ Ti \ Tr,
                         Gamma \vdash t \setminus in Tr \rightarrow
                         The Thomas The The Thomas The The Thomas The The Thomas The The Thomas The The Thomas The The Thomas The The 
                          Gamma \vdash (tproj \ t \ i) \setminus in \ Ti
        \mid \mathsf{T}_{\mathsf{-}}\mathsf{RNil} : \forall \ Gamma,
                          Gamma \vdash trnil \setminus in TRNil
        \mid T_{-}RCons : \forall Gamma \ i \ t \ T \ tr \ Tr,
                          Gamma \vdash t \setminus in T \rightarrow
                          Gamma \vdash tr \setminus in Tr \rightarrow
                         record_ty Tr \rightarrow
                         record_tm tr \rightarrow
                          Gamma \vdash (trcons \ i \ tr) \setminus in (TRCons \ i \ Tr)
where "Gamma '|-' t '\in' T" := (has_type Gamma\ t\ T).
Hint Constructors has_type.
```

```
Tactic Notation "has_type_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c \ "T\_Var" \mid Case\_aux \ c \ "T\_Abs" \mid Case\_aux \ c \ "T\_App" \mid Case\_aux \ c \ "T\_Proj" \mid Case\_aux \ c \ "T\_RNil" \mid Case\_aux \ c \ "T\_RCons" ].
```

### 10.3.1 Examples

Exercise: 2 stars (examples) Finish the proofs.

Feel free to use Coq's automation features in this proof. However, if you are not confident about how the type system works, you may want to carry out the proof first using the basic features (apply instead of eapply, in particular) and then perhaps compress it using automation.

```
Lemma typing_example_2:
  empty ⊢
     (tapp (tabs a (TRCons i1 (TArrow A A)
                          (TRCons i2 (TArrow B B)
                            TRNil))
                 (tproj (tvar a) i2))
              (trcons i1 (tabs a A (tvar a))
              (trcons i2 (tabs a B (tvar a))
               trnil))) \in
     (TArrow B B).
Proof.
   Admitted.
   Before starting to prove this fact (or the one above!), make sure you understand what it
is saying.
Example typing_nonexample:
  \neg \exists T
       (extend empty a (TRCons i2 (TArrow A A)
                                       TRNil)) \vdash
                  (trcons i1 (tabs a B (tvar a)) (tvar a)) \in
Proof.
   Admitted.
Example typing_nonexample_2 : \forall y,
  \neg \exists T,
     (extend empty y A) \vdash
             (tapp (tabs a (TRCons i1 A TRNil)
                         (tproj (tvar a) i1))
                       (trcons i1 (tvar y) (trcons i2 (tvar y) trnil))) \in
             T.
```

Proof. Admitted.

### 10.3.2 Properties of Typing

The proofs of progress and preservation for this system are essentially the same as for the pure simply typed lambda-calculus, but we need to add some technical lemmas involving records.

#### Well-Formedness

```
Lemma wf_rcd_lookup : \forall i T Ti,
  well_formed_ty T \rightarrow
  The Theorem Ti = Some Ti \rightarrow Ti
  well_formed_ty Ti.
Proof with eauto.
  intros i T.
  T_{-}cases (induction T) Case; intros; try solve by inversion.
  Case "TRCons".
     inversion H. subst. unfold Tlookup in H\theta.
     destruct (eq_id_dec i i\theta)...
     inversion H0. subst... Qed.
Lemma step_preserves_record_tm : \forall tr tr',
  record_tm tr \rightarrow
  tr ==> tr' \rightarrow
  record_tm tr'.
Proof.
  intros tr tr' Hrt Hstp.
  inversion Hrt; subst; inversion Hstp; subst; auto.
Qed.
Lemma has_type__wf : \forall \ Gamma \ t \ T,
  Gamma \vdash t \setminus in T \rightarrow well\_formed\_ty T.
Proof with eauto.
  intros Gamma t T Htyp.
  has_type_cases (induction Htyp) Case...
  Case "T_App".
     inversion IHHtyp1...
  Case "T_Proj".
     eapply wf_rcd_lookup...
Qed.
```

### Field Lookup

Lemma: If empty  $\vdash v : T$  and Tlookup i T returns Some Ti, then tlookup i v returns Some ti for some term ti such that empty  $\vdash ti \setminus Ti$ .

Proof: By induction on the typing derivation Htyp. Since Tlookup i  $T = \mathsf{Some}\ Ti$ , T must be a record type, this and the fact that v is a value eliminate most cases by inspection, leaving only the  $\mathsf{T}_{-}\mathsf{RCons}$  case.

If the last step in the typing derivation is by  $T_RCons$ , then  $t = trcons i\theta t tr$  and  $T = TRCons i\theta T Tr$  for some  $i\theta$ , t, tr, T and Tr.

This leaves two possiblities to consider - either  $i\theta = i$  or not.

- If  $i = i\theta$ , then since Tlookup i (TRCons  $i\theta$  T Tr) = Some Ti we have T = Ti. It follows that t itself satisfies the theorem.
- On the other hand, suppose  $i \neq i0$ . Then Tlookup i T = Tlookup i Tr and tlookup i t = tlookup i tr, so the result follows from the induction hypothesis.  $\square$

# Chapter 11

# Library MoreStlc

## 11.1 MoreStlc: More on the Simply Typed Lambda-Calculus

Require Export Stlc.

## 11.2 Simple Extensions to STLC

The simply typed lambda-calculus has enough structure to make its theoretical properties interesting, but it is not much of a programming language. In this chapter, we begin to close the gap with real-world languages by introducing a number of familiar features that have straightforward treatments at the level of typing.

### 11.2.1 Numbers

Adding types, constants, and primitive operations for numbers is easy – just a matter of combining the Types and Stlc chapters.

## 11.2.2 let-bindings

When writing a complex expression, it is often useful to give names to some of its subexpressions: this avoids repetition and often increases readability. Most languages provide one or more ways of doing this. In OCaml (and Coq), for example, we can write let x=t1 in t2 to mean "evaluate the expression t1 and bind the name x to the resulting value while evaluating t2."

Our let-binder follows OCaml's in choosing a call-by-value evaluation order, where the let-bound term must be fully evaluated before evaluation of the let-body can begin. The typing rule  $T_{-}Let$  tells us that the type of a let can be calculated by calculating the type of the let-bound term, extending the context with a binding with this type, and in this enriched context calculating the type of the body, which is then the type of the whole let expression.

At this point in the course, it's probably easier simply to look at the rules defining this new feature as to wade through a lot of english text conveying the same information. Here they are:

Syntax:

Reduction: t1 ==> t1'

```
(ST_Let1) let x=t1 in t2 ==> let x=t1' in t2
```

```
(ST_LetValue) let x=v1 in t2 ==> x:=v1t2 Typing: Gamma |- t1 : T1 Gamma , x:T1 |- t2 : T2
```

```
(T_Let) Gamma |- let x=t1 in t2 : T2
```

### 11.2.3 Pairs

Our functional programming examples in Coq have made frequent use of *pairs* of values. The type of such pairs is called a *product type*.

The formalization of pairs is almost too simple to be worth discussing. However, let's look briefly at the various parts of the definition to emphasize the common pattern.

In Coq, the primitive way of extracting the components of a pair is *pattern matching*. An alternative style is to take fst and snd – the first- and second-projection operators – as primitives. Just for fun, let's do our products this way. For example, here's how we'd write a function that takes a pair of numbers and returns the pair of their sum and difference:

```
\x:Nat*Nat.
let sum = x.fst + x.snd in
let diff = x.fst - x.snd in
(sum,diff)
```

Adding pairs to the simply typed lambda-calculus, then, involves adding two new forms of term – pairing, written (t1,t2), and projection, written t.fst for the first projection from t and t.snd for the second projection – plus one new type constructor,  $T1 \times T2$ , called the product of T1 and T2.

Syntax:

For evaluation, we need several new rules specifying how pairs and projection behave. t1 = > t1'

```
(ST_Pair1) (t1,t2) ==> (t1',t2)

t2 ==> t2'

(ST_Pair2) (v1,t2) ==> (v1,t2')

t1 ==> t1'

(ST_Fst1) t1.fst ==> t1'.fst

(ST_FstPair) (v1,v2).fst ==> v1

t1 ==> t1'

(ST_Snd1) t1.snd ==> t1'.snd
```

```
(ST\_SndPair) (v1,v2).snd ==> v2
```

Rules  $ST_FstPair$  and  $ST_SndPair$  specify that, when a fully evaluated pair meets a first or second projection, the result is the appropriate component. The congruence rules  $ST_Fst1$  and  $ST_Snd1$  allow reduction to proceed under projections, when the term being projected from has not yet been fully evaluated.  $ST_Pair1$  and  $ST_Pair2$  evaluate the parts of pairs: first the left part, and then – when a value appears on the left – the right part. The ordering arising from the use of the metavariables v and t in these rules enforces a left-to-right evaluation strategy for pairs. (Note the implicit convention that metavariables like v and v1 can only denote values.) We've also added a clause to the definition of values, above, specifying that (v1,v2) is a value. The fact that the components of a pair value must themselves be values ensures that a pair passed as an argument to a function will be fully evaluated before the function body starts executing.

The typing rules for pairs and projections are straightforward. Gamma  $\mid$ - t1 : T1 Gamma  $\mid$ - t2 : T2

```
(T_Pair) Gamma |- (t1,t2) : T1*T2
Gamma |- t1 : T11*T12
```

```
(T_Fst) Gamma |- t1.fst : T11
Gamma |- t1 : T11*T12
```

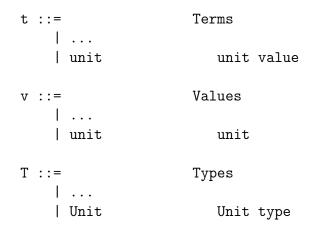

```
(T_Snd) Gamma |- t1.snd : T12
```

The rule  $T_{-}$ Pair says that (t1,t2) has type  $T1 \times T2$  if t1 has type T1 and t2 has type T2. Conversely, the rules  $T_{-}$ Fst and  $T_{-}$ Snd tell us that, if t1 has a product type  $T11 \times T12$  (i.e., if it will evaluate to a pair), then the types of the projections from this pair are T11 and T12.

### 11.2.4 Unit

Another handy base type, found especially in languages in the ML family, is the singleton type Unit. It has a single element – the term constant unit (with a small u) – and a typing rule making unit an element of Unit. We also add unit to the set of possible result values of computations – indeed, unit is the only possible result of evaluating an expression of type Unit.

Syntax:

Typing:

(T\_Unit) Gamma |- unit : Unit

It may seem a little strange to bother defining a type that has just one element – after all, wouldn't every computation living in such a type be trivial?

This is a fair question, and indeed in the STLC the *Unit* type is not especially critical (though we'll see two uses for it below). Where *Unit* really comes in handy is in richer languages with various sorts of *side effects* – e.g., assignment statements that mutate variables or pointers, exceptions and other sorts of nonlocal control structures, etc. In such languages, it is convenient to have a type for the (trivial) result of an expression that is evaluated only for its effect.

### 11.2.5 Sums

Many programs need to deal with values that can take two distinct forms. For example, we might identify employees in an accounting application using using *either* their name *or* their id number. A search function might return *either* a matching value *or* an error code.

These are specific examples of a binary *sum type*, which describes a set of values drawn from exactly two given types, e.g.

```
Nat + Bool
```

We create elements of these types by tagging elements of the component types. For example, if n is a Nat then inl v is an element of Nat+Bool; similarly, if b is a Bool then inr b is a Nat+Bool. The names of the tags inl and inr arise from thinking of them as functions

```
inl : Nat -> Nat + Bool
inr : Bool -> Nat + Bool
```

that "inject" elements of Nat or Bool into the left and right components of the sum type Nat+Bool. (But note that we don't actually treat them as functions in the way we formalize them: inl and inr are keywords, and inl t and inr t are primitive syntactic forms, not function applications. This allows us to give them their own special typing rules.)

In general, the elements of a type T1 + T2 consist of the elements of T1 tagged with the token inl, plus the elements of T2 tagged with inr.

One important usage of sums is signaling errors:

```
div : Nat -> Nat -> (Nat + Unit) =
div =
  \x:Nat. \y:Nat.
  if iszero y then
    inr unit
  else
  inl ...
```

The type Nat + Unit above is in fact isomorphic to **option nat** in Coq, and we've already seen how to signal errors with options.

To use elements of sum types, we introduce a case construct (a very simplified form of Coq's match) to destruct them. For example, the following procedure converts a Nat+Bool into a Nat:

```
getNat =
  \x:Nat+Bool.
  case x of
    inl n => n
  | inr b => if b then 1 else 0
```

```
More formally...
   Syntax:
       t ::=
                               Terms
            | inl T t
                                   tagging (left)
            | inr T t
                                   tagging (right)
            | case t of
                                   case
                 inl x => t
               | inr x => t
       v ::=
                               Values
            | ...
            | inl T v
                                   tagged value (left)
            | inr T v
                                   tagged value (right)
       T ::=
                               Types
            | ...
            I T + T
                                   sum type
   Evaluation:
   t1 ==> t1'
(ST_Inl) inl T t1 ==> inl T t1'
   t1 ==> t1'
(ST_Inr) inr T t1 ==> inr T t1'
   t0 ==> t0'
(ST\_Case) case t0 of inl x1 => t1 | inr x2 => t2 ==> case t0' of inl x1 => t1 | inr x2 =>
t2
(ST_CaseInl) case (inl T v0) of inl x1 => t1 | inr x2 => t2 ==> x1:=v0t1
(ST_CaseInr) case (inr T v0) of inl x1 => t1 | inr x2 => t2 ==> x2:=v\thetat2
   Typing: Gamma |- t1 : T1
```

```
Gamma |- t1 : T2

(T_Inr) Gamma |- inr T1 t1 : T1 + T2

Gamma |- t0 : T1+T2 Gamma , x1:T1 |- t1 : T Gamma , x2:T2 |- t2 : T
```

 $(T_Inl)$  Gamma |- inl T2 t1 : T1 + T2

```
(T_Case) Gamma |- case t0 of inl x1 => t1 | inr x2 => t2 : T
```

We use the type annotation in inl and inr to make the typing simpler, similarly to what we did for functions. Without this extra information, the typing rule  $T_-Inl$ , for example, would have to say that, once we have shown that t1 is an element of type T1, we can derive that  $inl\ t1$  is an element of T1 + T2 for any type T2. For example, we could derive both  $inl\ 5: Nat + Nat$  and  $inl\ 5: Nat + Bool$  (and infinitely many other types). This failure of uniqueness of types would mean that we cannot build a typechecking algorithm simply by "reading the rules from bottom to top" as we could for all the other features seen so far.

There are various ways to deal with this difficulty. One simple one – which we've adopted here – forces the programmer to explicitly annotate the "other side" of a sum type when performing an injection. This is rather heavyweight for programmers (and so real languages adopt other solutions), but it is easy to understand and formalize.

### 11.2.6 Lists

The typing features we have seen can be classified into base types like Bool, and type constructors like  $\rightarrow$  and  $\times$  that build new types from old ones. Another useful type constructor is List. For every type T, the type List T describes finite-length lists whose elements are drawn from T.

In principle, we could encode lists using pairs, sums and *recursive* types. But giving semantics to recursive types is non-trivial. Instead, we'll just discuss the special case of lists directly.

Below we give the syntax, semantics, and typing rules for lists. Except for the fact that explicit type annotations are mandatory on nil and cannot appear on cons, these lists are essentially identical to those we built in Coq. We use *lcase* to destruct lists, to avoid dealing with questions like "what is the head of the empty list?"

For example, here is a function that calculates the sum of the first two elements of a list of numbers:

```
| nil T
                                      nil value
             cons v v
                                      cons value
        T ::=
                                  Types
             | ...
             | List T
                                      list of Ts
  Reduction: t1 ==> t1'
(ST\_Cons1) cons t1 t2 ==> cons t1' t2
  t2 ==> t2'
(ST\_Cons2) cons v1 t2 ==> cons v1 t2'
  t1 ==> t1'
(ST_Lcase1) (lcase t1 of nil -> t2 | xh::xt -> t3) ==> (lcase t1' of nil -> t2 | xh::xt -> t3)
(ST_LcaseNil) (lcase nil T of nil -> t2 | xh::xt -> t3) ==> t2
(ST_LcaseCons) (lcase (cons vh vt) of nil -> t2 | xh::xt -> t3) ==> xh:=vh,xt:=vtt3
  Typing:
(T_Nil) Gamma |- nil T : List T
  Gamma |- t1 : T Gamma |- t2 : List T
(T_Cons) Gamma |- cons t1 t2: List T
  Gamma |- t1 : List T1 Gamma |- t2 : T Gamma , h:T1, t:List T1 |- t3 : T
(T_L \text{case}) \text{ Gamma} \mid - (\text{lcase } t1 \text{ of } nil \rightarrow t2 \mid h::t \rightarrow t3) : T
```

### 11.2.7 General Recursion

Another facility found in most programming languages (including Coq) is the ability to define recursive functions. For example, we might like to be able to define the factorial function like this:

```
fact = \x:Nat.
if x=0 then 1 else x * (fact (pred x)))
```

But this would require quite a bit of work to formalize: we'd have to introduce a notion of "function definitions" and carry around an "environment" of such definitions in the definition of the **step** relation.

Here is another way that is straightforward to formalize: instead of writing recursive definitions where the right-hand side can contain the identifier being defined, we can define

a fixed-point operator that performs the "unfolding" of the recursive definition in the right-hand side lazily during reduction.

```
fact =
    fix
        (\f:Nat->Nat.
        \x:Nat.
        if x=0 then 1 else x * (f (pred x)))
```

The intuition is that the higher-order function f passed to fix is a generator for the fact function: if fact is applied to a function that approximates the desired behavior of fact up to some number n (that is, a function that returns correct results on inputs less than or equal to n), then it returns a better approximation to fact – a function that returns correct results for inputs up to n+1. Applying fix to this generator returns its fixed point – a function that gives the desired behavior for all inputs n.

(The term "fixed point" has exactly the same sense as in ordinary mathematics, where a fixed point of a function f is an input x such that f(x) = x. Here, a fixed point of a function F of type (say)  $(Nat \rightarrow Nat)$ -> $(Nat \rightarrow Nat)$  is a function f such that F f is behaviorally equivalent to f.)

Syntax:

Reduction: t1 ==> t1

```
(ST_Fix1) fix t1 ==> fix t1'

F = \xspace xf:T1.t2
```

```
(ST_FixAbs) fix F ==> xf:=fix Ft2 Typing: Gamma |-t1:T1->T1|
```

```
(T_Fix) Gamma |- fix t1 : T1
```

Let's see how  $ST_FixAbs$  works by reducing fact 3 = fix F 3, where  $F = (\f. \x)$  if x=0 then 1 else  $x \times (f \text{ (pred x)}))$  (we are omitting type annotations for brevity here).

```
fix F 3
```

```
==> ST_FixAbs
(\x. if x=0 then 1 else x * (fix F (pred x))) 3
==> ST_AppAbs
if 3=0 then 1 else 3 * (fix F (pred 3))
==> ST_If0_Nonzero
```

```
3 * (fix F (pred 3))
==> ST\_FixAbs + ST\_Mult2
3 * ((\x). if x=0 then 1 else x * (fix F (pred x))) (pred 3))
==> ST_PredNat + ST_Mult2 + ST_App2
3 * ((\x) if x=0 then 1 else x * (fix F (pred x))) 2)
==> ST_AppAbs + ST_Mult2

```

Exercise: 1 star (halve\_fix) Translate this informal recursive definition into one using fix:

```
halve =
  \x:Nat.
  if x=0 then 0
  else if (pred x)=0 then 0
  else 1 + (halve (pred (pred x))))
```

Exercise: 1 star (fact\_steps) Write down the sequence of steps that the term fact 1 goes through to reduce to a normal form (assuming the usual reduction rules for arithmetic operations).

The ability to form the fixed point of a function of type  $T \to T$  for any T has some surprising consequences. In particular, it implies that *every* type is inhabited by some term. To see this, observe that, for every type T, we can define the term fix (\x:T.x) By  $T_-Fix$  and  $T_-Abs$ , this term has type T. By  $ST_-FixAbs$  it reduces to itself, over and over again. Thus it is an *undefined element* of T.

More usefully, here's an example using fix to define a two-argument recursive function:

```
equal =
  fix
  (\eq:Nat->Nat->Bool.
   \m:Nat. \n:Nat.
    if m=0 then iszero n
    else if n=0 then false
    else eq (pred m) (pred n))
```

And finally, here is an example where fix is used to define a *pair* of recursive functions (illustrating the fact that the type T1 in the rule  $T_-Fix$  need not be a function type):

```
evenodd =
  fix
    (\eo: (Nat->Bool * Nat->Bool).
    let e = \n:Nat. if n=0 then true else eo.snd (pred n) in
    let o = \n:Nat. if n=0 then false else eo.fst (pred n) in
        (e,o))

even = evenodd.fst
odd = evenodd.snd
```

### 11.2.8 Records

As a final example of a basic extension of the STLC, let's look briefly at how to define *records* and their types. Intuitively, records can be obtained from pairs by two kinds of generalization: they are n-ary products (rather than just binary) and their fields are accessed by *label* (rather than position).

This extension is conceptually a straightforward generalization of pairs and product types, but notationally it becomes a little heavier; for this reason, we postpone its formal treatment to a separate chapter (Records). Therefore records are not included in the extended exercise below, but they are used to motivate the Sub chapter.

Syntax:

Intuitively, the generalization is pretty obvious. But it's worth noticing that what we've actually written is rather informal: in particular, we've written "..." in several places to mean "any number of these," and we've omitted explicit mention of the usual side-condition that the labels of a record should not contain repetitions. It is possible to devise informal notations that are more precise, but these tend to be quite heavy and to obscure the main points of the definitions. So we'll leave these a bit loose here (they are informal anyway, after all) and do the work of tightening things up elsewhere (in chapter Records).

Reduction: ti ==> ti'

```
 \begin{array}{c} (ST\_Rcd) \; \{i1\_v1, \, ..., \, im\_vm, \, in\_ti, \, ...\} \; ==> \; \{i1\_v1, \, ..., \, im\_vm, \, in\_ti', \, ...\} \\ t1 \; ==> \; t1' \\ \hline \\ (ST\_Proj1) \; t1.i \; ==> \; t1'.i \\ \end{array}
```

(ST\_ProjRcd)  $\{..., i=vi, ...\}$ . i==>vi Again, these rules are a bit informal. For example, the first rule is intended to be read "if ti is the leftmost field that is not a value and if ti steps to ti", then the whole record steps..." In the last rule, the intention is that there should only be one field called i, and that all the other fields must contain values.

Typing: Gamma |- t1 : T1 ... Gamma |- tn : Tn

```
(T_Rcd) Gamma |- {i1=t1, ..., in=tn} : {i1:T1, ..., in:Tn} Gamma |- t : {..., i:Ti, ...}
```

```
(T_Proj) Gamma |- t.i : Ti
```

### **Encoding Records (Optional)**

There are several ways to make the above definitions precise.

- We can directly formalize the syntactic forms and inference rules, staying as close as possible to the form we've given them above. This is conceptually straightforward, and it's probably what we'd want to do if we were building a real compiler in particular, it will allow is to print error messages in the form that programmers will find easy to understand. But the formal versions of the rules will not be pretty at all!
- We could look for a smoother way of presenting records for example, a binary presentation with one constructor for the empty record and another constructor for adding a single field to an existing record, instead of a single monolithic constructor that builds a whole record at once. This is the right way to go if we are primarily interested in studying the metatheory of the calculi with records, since it leads to clean and elegant definitions and proofs. Chapter Records shows how this can be done.
- Alternatively, if we like, we can avoid formalizing records altogether, by stipulating that record notations are just informal shorthands for more complex expressions involving pairs and product types. We sketch this approach here.

First, observe that we can encode arbitrary-size tuples using nested pairs and the **unit** value. To avoid overloading the pair notation (t1,t2), we'll use curly braces without labels to write down tuples, so  $\{\}$  is the empty tuple,  $\{5\}$  is a singleton tuple,  $\{5,6\}$  is a 2-tuple (morally the same as a pair),  $\{5,6,7\}$  is a triple, etc.

```
{\tau_{t1}, t2, \ldots, tn\} \quad \quad \tau_{t1}, \tau_{t2}, \tau_{t1}, \tau_{t2}, \tau_{t2}, \tau_{t3}, \tau_{t4} \tau_{t4} \tau_{t4} \tau_{t5}
```

Similarly, we can encode tuple types using nested product types:

```
{T1, T2, ..., Tn} ----> Unit

*T1 * TRest where {T2, ..., Tn} ----> TRest
```

The operation of projecting a field from a tuple can be encoded using a sequence of second projections followed by a first projection:

```
t.0 ----> t.fst
t.(n+1) ----> (t.snd).n
```

Next, suppose that there is some total ordering on record labels, so that we can associate each label with a unique natural number. This number is called the *position* of the label. For example, we might assign positions like this:

LABEL	POSITION
a	0
b	1
С	2
foo	1004
bar	 10562

We use these positions to encode record values as tuples (i.e., as nested pairs) by sorting the fields according to their positions. For example:

```
{a=5, b=6} ----> {5,6}

{a=5, c=7} ----> {5,unit,7}

{c=7, a=5} ----> {5,unit,7}

{c=5, b=3} ----> {unit,3,5}

{f=8,c=5,a=7} ----> {7,unit,5,unit,unit,8}

{f=8,c=5} ----> {unit,5,unit,unit,8}
```

Note that each field appears in the position associated with its label, that the size of the tuple is determined by the label with the highest position, and that we fill in unused positions with unit.

We do exactly the same thing with record types:

Finally, record projection is encoded as a tuple projection from the appropriate position:

```
t.l ---> t.(position of 1)
```

It is not hard to check that all the typing rules for the original "direct" presentation of records are validated by this encoding. (The reduction rules are "almost validated" – not quite, because the encoding reorders fields.)

Of course, this encoding will not be very efficient if we happen to use a record with label bar! But things are not actually as bad as they might seem: for example, if we assume that our compiler can see the whole program at the same time, we can *choose* the numbering of labels so that we assign small positions to the most frequently used labels. Indeed, there are industrial compilers that essentially do this!

### Variants (Optional Reading)

Just as products can be generalized to records, sums can be generalized to n-ary labeled types called *variants*. Instead of T1+T2, we can write something like  $\langle l1:T1,l2:T2,...ln:Tn\rangle$  where l1,l2,... are field labels which are used both to build instances and as case arm labels.

These n-ary variants give us almost enough mechanism to build arbitrary inductive data types like lists and trees from scratch – the only thing missing is a way to allow *recursion* in type definitions. We won't cover this here, but detailed treatments can be found in many textbooks – e.g., Types and Programming Languages.

## 11.3 Exercise: Formalizing the Extensions

Exercise: 4 stars, advanced (STLC\_extensions) Formalizing the extensions (not including the optional ones) is left to you. We've provided the necessary extensions to the syntax of terms and types, and we've included a few examples that you can test your definitions with to make sure they are working as expected. You'll fill in the rest of the definitions and extend all the proofs accordingly.

A good strategy is to work on the extensions one at a time, in multiple passes, rather than trying to work through the file from start to finish in a single pass. For each definition or proof, begin by reading carefully through the parts that are provided for you, referring to the text in the Stlc chapter for high-level intuitions and the embedded comments for detailed mechanics.

A good order for attempting the extensions is:

- numbers first (since they are both familiar and simple)
- products and units
- let (which involves binding)
- sums (which involve slightly more complex binding)
- lists (which involve yet more complex binding)
- fix

Module STLCEXTENDED.

### Syntax and Operational Semantics

```

```

### 11.3.1 Examples

This section presents formalized versions of the examples from above (plus several more). The ones at the beginning focus on specific features; you can use these to make sure your definition of a given feature is reasonable before moving on to extending the proofs later in the file with the cases relating to this feature. The later examples require all the features together, so you'll need to come back to these when you've got all the definitions filled in.

**Preliminaries** 

Module EXAMPLES.

```
First, let's define a few variable names:
```

```
Notation a := (Id 0).
Notation f := (Id 1).
Notation g := (Id 2).
Notation I := (Id 3).
Notation k := (Id 6).
Notation i1 := (Id 7).
Notation i2 := (Id 8).
Notation x := (Id 9).
Notation y := (Id 10).
Notation processSum := (Id 11).
Notation n := (Id 12).
Notation eq := (Id 13).
Notation m := (Id 14).
Notation evenodd := (Id 15).
Notation even := (Id 16).
Notation odd := (Id 17).
Notation eo := (Id 18).
```

Next, a bit of Coq hackery to automate searching for typing derivations. You don't need to understand this bit in detail – just have a look over it so that you'll know what to look for if you ever find yourself needing to make custom extensions to auto.

The following Hint declarations say that, whenever auto arrives at a goal of the form  $(Gamma \vdash (tapp\ e1\ e1) \setminus in\ T)$ , it should consider eapply T\_App, leaving an existential variable for the middle type T1, and similar for *lcase*. That variable will then be filled in during the search for type derivations for e1 and e2. We also include a hint to "try harder" when solving equality goals; this is useful to automate uses of T\_Var (which includes an equality as a precondition).

```
Hint Extern 2 (has_type \_ (tapp \_ \_) \_) \Rightarrow eapply T_App; auto.
Hint Extern 2 (\_ = \_) \Rightarrow compute; reflexivity.
```

### Numbers

Remove the comment braces once you've implemented enough of the definitions that you think this should work.

End NUMTEST.

### **Products**

End PRODTEST.

# Library Typechecking

## 12.1 MoreStlc: A Typechecker for STLC

Require Export Stlc.

The **has\_type** relation of the STLC defines what it means for a term to belong to a type (in some context). But it doesn't, by itself, tell us how to *check* whether or not a term is well typed.

Fortunately, the rules defining **has\_type** are *syntax directed* – they exactly follow the shape of the term. This makes it straightforward to translate the typing rules into clauses of a typechecking *function* that takes a term and a context and either returns the term's type or else signals that the term is not typable.

```
Module STLCCHECKER. Import STLC.
```

## 12.1.1 Comparing Types

First, we need a function to compare two types for equality...

```
Fixpoint beq_ty (T1 \ T2:\mathbf{ty}): \mathbf{bool}:= match T1,T2 with | \ \mathsf{TBool}, \ \mathsf{TBool} \Rightarrow true | \ \mathsf{TArrow} \ T11 \ T12, \ \mathsf{TArrow} \ T21 \ T22 \Rightarrow andb (\mathsf{beq\_ty} \ T11 \ T21) \ (\mathsf{beq\_ty} \ T12 \ T22) | \ \mathsf{-,-} \Rightarrow false end.
```

... and we need to establish the usual two-way connection between the boolean result returned by beq\_ty and the logical proposition that its inputs are equal.

```
Lemma beq_ty_refl : \forall T1,
```

```
beq_ty T1 T1 = true.

```

## 12.1.2 The Typechecker

Now here's the typechecker. It works by walking over the structure of the given term, returning either Some T or None. Each time we make a recursive call to find out the types of the subterms, we need to pattern-match on the results to make sure that they are not None. Also, in the tapp case, we use pattern matching to extract the left- and right-hand sides of the function's arrow type (and fail if the type of the function is not TArrow  $T11\ T12$  for some T1 and T2).

```
Fixpoint type_check (Gamma:context) (t:tm) : option ty :=
  match t with
    tvar x \Rightarrow Gamma \ x
   | tabs x T11 t12 \Rightarrow match type_check (extend Gamma \ x \ T11) t12 with
                                  Some T12 \Rightarrow Some (TArrow T11 T12)
                                  \downarrow \_ \Rightarrow \mathsf{None}
                                end
  | tapp t1 t2 \Rightarrow match type_check Gamma t1, type_check Gamma t2 with
                             | Some (TArrow T11 T12), Some T2 \Rightarrow
                                if beq_ty T11 T2 then Some T12 else None
                             | \_,\_ \Rightarrow \mathsf{None}
                          end
   ttrue \Rightarrow Some TBool
    tfalse \Rightarrow Some TBool
   tif x \ t \ f \Rightarrow \mathtt{match} type_check Gamma \ x with
                           | Some TBool \Rightarrow
                              match type_check Gamma\ t, type_check Gamma\ f with
                                 | Some T1, Some T2 \Rightarrow
                                    if beq_ty T1 T2 then Some T1 else None
```

```
\begin{array}{c} |\ \_,\_ \Rightarrow \mathsf{None} \\ \mathsf{end} \\ |\ \_ \Rightarrow \mathsf{None} \\ \mathsf{end} \end{array}
```

end.

## 12.1.3 Properties

To verify that this typechecking algorithm is the correct one, we show that it is *sound* and *complete* for the original **has\_type** relation – that is, **type\_check** and **has\_type** define the same partial function.

## 13.2 Progress

As before, the *progress* theorem tells us that closed, well-typed terms are not stuck: either a well-typed term is a value, or it can take an evaluation step. The proof is a relatively straightforward extension of the progress proof we saw in the Types chapter.

```
Theorem progress: \forall t \ T,
empty \vdash t \setminus \text{in } T \rightarrow \text{value } t \vee \exists t', t ==> t'.
Proof: by induction on the derivation of \vdash t \setminus \text{in } T.
```

- The last rule of the derivation cannot be  $T_{-}Var$ , since a variable is never well typed in an empty context.
- The T\_True, T\_False, and T\_Abs cases are trivial, since in each of these cases we know immediately that t is a value.
- If the last rule of the derivation was  $T_{-}App$ , then t = t1 t2, and we know that t1 and t2 are also well typed in the empty context; in particular, there exists a type T2 such that  $\vdash t1 \mid T2 \rightarrow T$  and  $\vdash t2 \mid T2$ . By the induction hypothesis, either t1 is a value or it can take an evaluation step.

- If t1 is a value, we now consider t2, which by the other induction hypothesis must also either be a value or take an evaluation step.
  - \* Suppose t2 is a value. Since t1 is a value with an arrow type, it must be a lambda abstraction; hence t1 t2 can take a step by  $\mathsf{ST\_AppAbs}$ .
  - \* Otherwise, t2 can take a step, and hence so can t1 t2 by  $ST\_App2$ .
- If t1 can take a step, then so can t1 t2 by  $ST\_App1$ .
- If the last rule of the derivation was  $T_{-}$ lf, then t = if t1 then t2 else t3, where t1 has type Bool. By the IH, t1 either is a value or takes a step.
  - If t1 is a value, then since it has type Bool it must be either true or false. If it is true, then t steps to t2; otherwise it steps to t3.
  - Otherwise, t1 takes a step, and therefore so does t (by  $ST_If$ ).

```

### 13.3 Preservation

The other half of the type soundness property is the preservation of types during reduction. For this, we need to develop some technical machinery for reasoning about variables and substitution. Working from top to bottom (the high-level property we are actually interested in to the lowest-level technical lemmas that are needed by various cases of the more interesting proofs), the story goes like this:

- The *preservation theorem* is proved by induction on a typing derivation, pretty much as we did in the Types chapter. The one case that is significantly different is the one for the ST\_AppAbs rule, which is defined using the substitution operation. To see that this step preserves typing, we need to know that the substitution itself does. So we prove a...
- substitution lemma, stating that substituting a (closed) term s for a variable x in a term t preserves the type of t. The proof goes by induction on the form of t and requires looking at all the different cases in the definition of substitition. This time, the tricky cases are the ones for variables and for function abstractions. In both cases, we discover that we need to take a term s that has been shown to be well-typed in some context Gamma and consider the same term s in a slightly different context Gamma'. For this we prove a...
- context invariance lemma, showing that typing is preserved under "inessential changes" to the context Gamma in particular, changes that do not affect any of the free variables of the term. For this, we need a careful definition of
- the *free variables* of a term i.e., the variables occurring in the term that are not in the scope of a function abstraction that binds them.

#### 13.3.1 Free Occurrences

A variable  $\times$  appears free in a term t if t contains some occurrence of  $\times$  that is not under an abstraction labeled x. For example:

- y appears free, but x does not, in  $\xspace x: T \to U$ . x y
- both x and y appear free in  $(\x: T \to U. \x y) \x$
- no variables appear free in  $\xspace x: T \to U$ .  $\xspace y: T$ .  $\xspace x$

```
Inductive appears_free_in : id \rightarrow tm \rightarrow Prop :=
  | afi_var : \forall x
       appears_free_in x (tvar x)
  | afi_app1 : \forall x t1 t2,
       appears_free_in x t1 \rightarrow appears_free_in x (tapp t1 t2)
  | afi_app2 : \forall x t1 t2,
        appears_free_in x \ t2 \rightarrow appears_free_in \ x \ (tapp \ t1 \ t2)
  | afi_abs : \forall x y T11 t12,
       y \neq x \rightarrow
       appears_free_in x t12 \rightarrow
       appears_free_in x (tabs y T11 t12)
  | afi_if1 : \forall x t1 t2 t3,
       appears_free_in x t1 \rightarrow
       appears_free_in x (tif t1 t2 t3)
  | afi_if2 : \forall x t1 t2 t3,
       appears_free_in x t2 \rightarrow
        appears_free_in x (tif t1 t2 t3)
  | afi_if3 : \forall x t1 t2 t3,
       appears_free_in x \ t3 \rightarrow
       appears_free_in x (tif t1 t2 t3).
Tactic Notation "afi_cases" tactic(first) ident(c) :=
  first;
  [ Case\_aux \ c "afi_var"
    Case\_aux \ c "afi_app1" | Case\_aux \ c "afi_app2"
    Case\_aux \ c "afi_abs"
    Case\_aux \ c "afi_if1" | Case\_aux \ c "afi_if2"
   Case\_aux \ c "afi_if3" ].
Hint Constructors appears_free_in.
```

A term in which no variables appear free is said to be *closed*.

```
Definition closed (t:tm) :=
  \forall x, \neg appears\_free\_in x t.
```

### 13.3.2 Substitution

We first need a technical lemma connecting free variables and typing contexts. If a variable x appears free in a term t, and if we know t is well typed in context Gamma, then it must be the case that Gamma assigns a type to x.

```
Lemma free_in_context : \forall x \ t \ T \ Gamma, 
 appears_free_in x \ t \rightarrow

Gamma \vdash t \setminus \text{in } T \rightarrow

\exists T', Gamma \ x = \text{Some } T'.
```

*Proof*: We show, by induction on the proof that x appears free in t, that, for all contexts Gamma, if t is well typed under Gamma, then Gamma assigns some type to x.

- If the last rule used was afi\_var, then t = x, and from the assumption that t is well typed under Gamma we have immediately that Gamma assigns a type to x.
- If the last rule used was  $afi_app1$ , then t = t1 t2 and x appears free in t1. Since t is well typed under Gamma, we can see from the typing rules that t1 must also be, and the IH then tells us that Gamma assigns x a type.
- Almost all the other cases are similar: x appears free in a subterm of t, and since t is well typed under Gamma, we know the subterm of t in which x appears is well typed under Gamma as well, and the IH gives us exactly the conclusion we want.
- The only remaining case is  $\mathsf{afi}_{-}\mathsf{abs}$ . In this case  $t = \y: T11.t12$ , and x appears free in t12; we also know that x is different from y. The difference from the previous cases is that whereas t is well typed under Gamma, its body t12 is well typed under (Gamma, y: T11), so the IH allows us to conclude that x is assigned some type by the extended context (Gamma, y: T11). To conclude that Gamma assigns a type to x, we appeal to lemma extend\_neq, noting that x and y are different variables.

#### Proof.

```
intros x t T Gamma H H0. generalize dependent Gamma. generalize dependent T. afi\_cases (induction H) Case; intros; try solve [inversion H0; eauto]. Case "afi\_abs". inversion H1; subst. apply IHappears\_free\_in in H7. rewrite extend_neq in H7; assumption. Qed.
```

Next, we'll need the fact that any term t which is well typed in the empty context is closed – that is, it has no free variables.

Exercise: 2 stars, optional (typable\_empty\_\_closed) Corollary typable\_empty\_\_closed :  $\forall t \ T$ ,

```
\begin{array}{l} \mathsf{empty} \vdash t \ \backslash \mathsf{in} \ T \to \\ \mathsf{closed} \ t. \end{array}
```

Proof.

Admitted.

Sometimes, when we have a proof  $Gamma \vdash t : T$ , we will need to replace Gamma by a different context Gamma. When is it safe to do this? Intuitively, it must at least be the case that Gamma assigns the same types as Gamma to all the variables that appear free in t. In fact, this is the only condition that is needed.

```
Lemma context_invariance : \forall Gamma Gamma' t T, Gamma \vdash t \setminus in T \rightarrow (\forall x, appears_free_in x t \rightarrow Gamma x = Gamma' x) \rightarrow Gamma' \vdash t \setminus in T.
```

*Proof*: By induction on the derivation of  $Gamma \vdash t \setminus in T$ .

- If the last rule in the derivation was  $T_{\text{-}}Var$ , then t = x and  $Gamma \ x = T$ . By assumption,  $Gamma' \ x = T$  as well, and hence  $Gamma' \vdash t \setminus in T$  by  $T_{\text{-}}Var$ .
- If the last rule was T\_Abs, then  $t = \y: T11$ . t12, with  $T = T11 \rightarrow T12$  and Gamma,  $y: T11 \vdash t12 \$  in T12. The induction hypothesis is that for any context Gamma", if Gamma, y: T11 and Gamma" assign the same types to all the free variables in t12, then t12 has type T12 under Gamma". Let Gamma be a context which agrees with Gamma on the free variables in t; we must show Gamma  $\vdash \y: T11$ .  $t12 \$  in  $T11 \rightarrow T12$ .

By T\_Abs, it suffices to show that Gamma', y: $T11 \vdash t12 \setminus in T12$ . By the IH (setting Gamma'' = Gamma', y:T11), it suffices to show that Gamma, y:T11 and Gamma', y:T11 agree on all the variables that appear free in t12.

Any variable occurring free in t12 must either be y, or some other variable. Gamma, y: T11 and Gamma', y: T11 clearly agree on y. Otherwise, we note that any variable other than y which occurs free in t12 also occurs free in t = y: t11. t12, and by assumption Gamma and Gamma' agree on all such variables, and hence so do Gamma, y: t11 and t11.

• If the last rule was  $T_-\mathsf{App}$ , then t = t1 t2, with  $Gamma \vdash t1 \setminus \mathsf{in}\ T2 \to T$  and  $Gamma \vdash t2 \setminus \mathsf{in}\ T2$ . One induction hypothesis states that for all contexts Gamma, if Gamma agrees with Gamma on the free variables in t1, then t1 has type  $t2 \to t2$  under t3 under t4 days a similar IH for t4. We must show that t4 t4 also has type t4 under t4 under t4 days a sumption that t4 and t4 each have the same type under t4 days a under t4 days a under t4 days a under t4 days a under t4 days and t4 each have the same type under t4 days a under t4 days and t4 days and t4 each have the same type under t4 days a under t4 days and t4 days are days and t4 days and t4 days and t4 days are days are days and t4 days are days and t4 days are days are days and t4 days are days are days and t4 days are days are days are days and t4 days are days are days and t4 days are days are

are also free in t1 t2, and similarly for free variables in t2; hence the desired result follows by the two IHs.

intros. generalize dependent Gamma'.  $has\_type\_cases$  (induction H) Case; intros; auto. Case "T\_Var". apply T\_Var. rewrite  $\leftarrow H0...$  Case "T\_Abs".

unfold extend. destruct (eq\_id\_dec x0 x1)...

Case "T\_App".

apply T\_App with T11...

Proof with eauto.

Qed.

Now we come to the conceptual heart of the proof that reduction preserves types – namely, the observation that substitution preserves types.

Formally, the so-called Substitution Lemma says this: suppose we have a term t with a free variable x, and suppose we've been able to assign a type T to t under the assumption that x has some type U. Also, suppose that we have some other term v and that we've shown that v has type U. Then, since v satisfies the assumption we made about x when typing t, we should be able to substitute v for each of the occurrences of x in t and obtain a new term that still has type T.

Lemma: If  $Gamma, x: U \vdash t \setminus in T \text{ and } \vdash v \setminus in U$ , then  $Gamma \vdash [x:=v]t \setminus in T$ .

```
 \begin{array}{l} \texttt{Lemma substitution\_preserves\_typing}: \forall \ Gamma \ x \ U \ t \ v \ T, \\ \texttt{extend} \ Gamma \ x \ U \vdash t \setminus \texttt{in} \ T \rightarrow \\ \texttt{empty} \vdash v \setminus \texttt{in} \ U \rightarrow \\ Gamma \vdash [x := v] \ t \setminus \texttt{in} \ T. \end{array}
```

One technical subtlety in the statement of the lemma is that we assign v the type U in the empty context – in other words, we assume v is closed. This assumption considerably simplifies the T\_Abs case of the proof (compared to assuming  $Gamma \vdash v \setminus in U$ , which would be the other reasonable assumption at this point) because the context invariance lemma then tells us that v has type U in any context at all – we don't have to worry about free variables in v clashing with the variable being introduced into the context by T\_Abs.

*Proof*: We prove, by induction on t, that, for all T and Gamma, if  $Gamma, x: U \vdash t \setminus T$  and  $T \vdash U$ , then  $Gamma \vdash [x:=v]t \setminus T$ .

- If t is a variable, there are two cases to consider, depending on whether t is x or some other variable.
  - If t = x, then from the fact that Gamma,  $x: U \vdash x \setminus in T$  we conclude that U = T. We must show that [x:=v]x = v has type T under Gamma, given the assumption

that v has type U = T under the empty context. This follows from context invariance: if a closed term has type T in the empty context, it has that type in any context.

- If t is some variable y that is not equal to x, then we need only note that y has the same type under Gamma, x: U as under Gamma.
- If t is an abstraction \y: T11. t12, then the IH tells us, for all Gamma' and T', that if Gamma',x:  $U \vdash t12 \setminus in T$ ' and  $\vdash v \setminus in U$ , then Gamma'  $\vdash [x:=v]t12 \setminus in T$ '.

The substitution in the conclusion behaves differently, depending on whether  $\boldsymbol{x}$  and  $\boldsymbol{y}$  are the same variable name.

First, suppose x = y. Then, by the definition of substitution, [x:=v]t = t, so we just need to show  $Gamma \vdash t \mid n$ . But we know  $Gamma,x:U \vdash t:T$ , and since the variable y does not appear free in y:T11. t12, the context invariance lemma yields  $Gamma \vdash t \mid n$ .

Second, suppose  $x \neq y$ . We know  $Gamma,x:U,y:T11 \vdash t12 \setminus in T12$  by inversion of the typing relation, and  $Gamma,y:T11,x:U \vdash t12 \setminus in T12$  follows from this by the context invariance lemma, so the IH applies, giving us  $Gamma,y:T11 \vdash [x:=v]t12 \setminus in T12$ . By  $T_-Abs$ ,  $Gamma \vdash \y:T11$ .  $[x:=v]t12 \setminus in T11 \rightarrow T12$ , and by the definition of substitution (noting that  $x \neq y$ ),  $Gamma \vdash \y:T11$ .  $[x:=v]t12 \setminus in T11 \rightarrow T12$  as required.

- If t is an application t1 t2, the result follows straightforwardly from the definition of substitution and the induction hypotheses.
- The remaining cases are similar to the application case.

Another technical note: This proof is a rare case where an induction on terms, rather than typing derivations, yields a simpler argument. The reason for this is that the assumption extend  $Gamma \times U \vdash t \setminus in T$  is not completely generic, in the sense that one of the "slots" in the typing relation – namely the context – is not just a variable, and this means that Coq's native induction tactic does not give us the induction hypothesis that we want. It is possible to work around this, but the needed generalization is a little tricky. The term t, on the other hand, is completely generic.

```
Proof with eauto.

      subst. rewrite neg_id...
Qed.
```

The substitution lemma can be viewed as a kind of "commutation" property. Intuitively, it says that substitution and typing can be done in either order: we can either assign types to the terms t and v separately (under suitable contexts) and then combine them using substitution, or we can substitute first and then assign a type to [x:=v] t – the result is the same either way.

#### 13.3.3 Main Theorem

We now have the tools we need to prove preservation: if a closed term t has type T, and takes an evaluation step to t, then t is also a closed term with type T. In other words, the small-step evaluation relation preserves types.

```
Theorem preservation : \forall t \ t' \ T, empty \vdash t \setminus \text{in } T \rightarrow t => t' \rightarrow \text{empty} \vdash t' \setminus \text{in } T.

Proof: by induction on the derivation of \vdash t \setminus \text{in } T.
```

• We can immediately rule out T\_Var, T\_Abs, T\_True, and T\_False as the final rules in the derivation, since in each of these cases t cannot take a step.

- If the last rule in the derivation was  $T_App$ , then t = t1 t2. There are three cases to consider, one for each rule that could have been used to show that t1 t2 takes a step to t'.
  - If t1 t2 takes a step by  $ST\_App1$ , with t1 stepping to t1, then by the IH t1 has the same type as t1, and hence t1 t2 has the same type as t1 t2.
  - The ST\_App2 case is similar.
  - If t1 t2 takes a step by  $ST\_AppAbs$ , then  $t1 = \xi : T11.t12$  and t1 t2 steps to [x:=t2]t12; the desired result now follows from the fact that substitution preserves types.
- If the last rule in the derivation was  $T_{-}$ lf, then t = if t1 then t2 else t3, and there are again three cases depending on how t steps.
  - If t steps to t2 or t3, the result is immediate, since t2 and t3 have the same type as t.
  - Otherwise, t steps by ST\_If, and the desired conclusion follows directly from the induction hypothesis.

**Exercise:** 2 stars (subject\_expansion\_stlc) An exercise in the Types chapter asked about the subject expansion property for the simple language of arithmetic and boolean expressions. Does this property hold for STLC? That is, is it always the case that, if t ==> t' and has\_type t' T, then empty  $\vdash t \mid T$ ? If so, prove it. If not, give a counter-example not involving conditionals.

# 13.4 Type Soundness

Exercise: 2 stars, optional (type\_soundness) Put progress and preservation together and show that a well-typed term can *never* reach a stuck state.

# 13.5 Uniqueness of Types

Exercise: 3 stars (types\_unique) Another pleasant property of the STLC is that types are unique: a given term (in a given context) has at most one type. Formalize this statement and prove it.

### 13.6 Additional Exercises

Exercise: 1 star (progress\_preservation\_statement) Without peeking, write down the progress and preservation theorems for the simply typed lambda-calculus.  $\Box$ 

Exercise: 2 stars (stlc\_variation1) Suppose we add a new term zap with the following reduction rule:

```
(ST_Zap) t ==> zap and the following typing rule:
```

(T\_Zap) Gamma |- zap : T Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of **step**
- Progress
- Preservation

Exercise: 2 stars (stlc\_variation2) Suppose instead that we add a new term foo with the following reduction rules:

$$(ST_Foo1) (x:A. x) ==> foo$$

(ST\_Foo2) foo ==> true Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of **step**
- Progress

• Preservation

Exercise: 2 stars (stlc\_variation3) Suppose instead that we remove the rule ST\_App1 from the step relation. Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of **step**
- Progress

• Preservation

Exercise: 2 stars, optional (stlc\_variation4) Suppose instead that we add the following new rule to the reduction relation:

(ST\_FunnyIfTrue) (if true then t1 else t2) ==> true Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of **step**
- Progress
- Preservation

**Exercise: 2 stars, optional (stlc\_variation5)** Suppose instead that we add the following new rule to the typing relation: Gamma |- t1 \in Bool->Bool->Bool Gamma |- t2 \in Bool

(T\_FunnyApp) Gamma |- t1 t2 \in Bool Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of **step**
- Progress
- Preservation

Exercise: 2 stars, optional (stlc\_variation6) Suppose instead that we add the following new rule to the typing relation: Gamma |- t1 \in Bool Gamma |- t2 \in Bool

(T\_FunnyApp') Gamma |- t1 t2 \in Bool Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of **step**
- Progress
- Preservation

Exercise: 2 stars, optional (stlc\_variation7) Suppose we add the following new rule to the typing relation of the STLC:

(T\_FunnyAbs) |- \x:Bool.t \in Bool Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of **step**
- Progress
- Preservation

End STLCPROP.

### 13.6.1 Exercise: STLC with Arithmetic

To see how the STLC might function as the core of a real programming language, let's extend it with a concrete base type of numbers and some constants and primitive operators.

Module STLCARITH.

To types, we add a base type of natural numbers (and remove booleans, for brevity)

```
\begin{array}{l} \text{Inductive } \textbf{ty} : \texttt{Type} := \\ \mid \texttt{TArrow} : \textbf{ty} \rightarrow \textbf{ty} \rightarrow \textbf{ty} \\ \mid \texttt{TNat} : \textbf{ty}. \end{array}
```

To terms, we add natural number constants, along with successor, predecessor, multiplication, and zero-testing...

```
Inductive tm: Type :=  | tvar: id \rightarrow tm | tapp: tm \rightarrow tm \rightarrow tm | tabs: id \rightarrow ty \rightarrow tm \rightarrow tm | tabs: id \rightarrow ty \rightarrow tm | tnat: nat \rightarrow tm | tsucc: tm \rightarrow tm | tpred: tm \rightarrow tm | tmult: tm \rightarrow tm \rightarrow tm | tif0: tm \rightarrow tm \rightarrow tm | tif0: tm \rightarrow tm \rightarrow tm.

Tactic Notation "t_cases" tactic(first) \ ident(c) := first; | Case\_aux \ c "tvar" | Case\_aux \ c "tapp" | Case\_aux \ c "tvat" | Case\_aux \ c "tnat" | Case\_aux \ c "tsucc" | Case\_aux \ c "tpred" | Case\_aux \ c "tif0" |.
```

Exercise: 4 stars (stlc\_arith) Finish formalizing the definition and properties of the STLC extended with arithmetic. Specifically:

- Copy the whole development of STLC that we went through above (from the definition of values through the Progress theorem), and paste it into the file at this point.
- Extend the definitions of the **subst** operation and the **step** relation to include appropriate clauses for the arithmetic operators.
- Extend the proofs of all the properties (up to soundness) of the original STLC to deal with the new syntactic forms. Make sure Coq accepts the whole file.

П

End STLCARITH.

# Chapter 14

# Library Stlc

# 14.1 Stlc: The Simply Typed Lambda-Calculus

Require Export Types.

# 14.2 The Simply Typed Lambda-Calculus

The simply typed lambda-calculus (STLC) is a tiny core calculus embodying the key concept of *functional abstraction*, which shows up in pretty much every real-world programming language in some form (functions, procedures, methods, etc.).

We will follow exactly the same pattern as in the previous chapter when formalizing this calculus (syntax, small-step semantics, typing rules) and its main properties (progress and preservation). The new technical challenges (which will take some work to deal with) all arise from the mechanisms of *variable binding* and *substitution*.

#### 14.2.1 Overview

The STLC is built on some collection of base types – booleans, numbers, strings, etc. The exact choice of base types doesn't matter – the construction of the language and its theoretical properties work out pretty much the same – so for the sake of brevity let's take just Bool for the moment. At the end of the chapter we'll see how to add more base types, and in later chapters we'll enrich the pure STLC with other useful constructs like pairs, records, subtyping, and mutable state.

Starting from the booleans, we add three things:

- variables
- function abstractions
- application

This gives us the following collection of abstract syntax constructors (written out here in informal BNF notation – we'll formalize it below).

Informal concrete syntax: t := x variable |  $\xspace x: T1.t2$  abstraction | t1 t2 application | true constant true | false constant false | if t1 then t2 else t3 conditional

The  $\$  symbol (backslash, in ascii) in a function abstraction  $\$ x: T1.t2 is generally written as a greek letter "lambda" (hence the name of the calculus). The variable x is called the parameter to the function; the term t1 is its body. The annotation : T specifies the type of arguments that the function can be applied to.

Some examples:

• \x:Bool. x

The identity function for booleans.

(\x:Bool. x) true

The identity function for booleans, applied to the boolean true.

• \x:Bool. if x then false else true

The boolean "not" function.

• \x:Bool. true

The constant function that takes every (boolean) argument to true.

• \x:Bool. \y:Bool. x

A two-argument function that takes two booleans and returns the first one. (Note that, as in Coq, a two-argument function is really a one-argument function whose body is also a one-argument function.)

• (\x:Bool. \y:Bool. x) false true

A two-argument function that takes two booleans and returns the first one, applied to the booleans false and true.

Note that, as in Coq, application associates to the left – i.e., this expression is parsed as ((x:Bool. y:Bool. x) false) true.

\f:Bool→Bool. f (f true)

A higher-order function that takes a *function* f (from booleans to booleans) as an argument, applies f to true, and applies f again to the result.

• ( $\fint f:Bool \rightarrow Bool. f (f true)$ ) ( $\xi sool. false$ )

The same higher-order function, applied to the constantly false function.

As the last several examples show, the STLC is a language of *higher-order* functions: we can write down functions that take other functions as arguments and/or return other functions as results.

Another point to note is that the STLC doesn't provide any primitive syntax for defining named functions – all functions are "anonymous." We'll see in chapter MoreStlc that it is easy to add named functions to what we've got – indeed, the fundamental naming and binding mechanisms are exactly the same.

The *types* of the STLC include Bool, which classifies the boolean constants true and false as well as more complex computations that yield booleans, plus *arrow types* that classify functions.

 $T ::= Bool \mid T1 \rightarrow T2$  For example:

- \x:Bool. false has type Bool→Bool
- \x:Bool. x has type Bool→Bool
- (\x:Bool. x) true has type Bool
- $\xspace \xspace \x$
- (\x:Bool. \y:Bool. x) false has type Bool→Bool
- (\x:Bool. \y:Bool. x) false true has type Bool

## 14.2.2 Syntax

Module STLC.

#### **Types**

```
\begin{array}{l} \texttt{Inductive } \ \textbf{ty} : \ \texttt{Type} := \\ | \ \texttt{TBool} : \ \textbf{ty} \\ | \ \texttt{TArrow} : \ \textbf{ty} \rightarrow \ \textbf{ty} \rightarrow \ \textbf{ty}. \end{array}
```

#### **Terms**

```
Inductive tm: Type :=  | tvar: id \rightarrow tm | tapp: tm \rightarrow tm \rightarrow tm | tabs: id \rightarrow ty \rightarrow tm \rightarrow tm | ttrue: tm | tfalse: tm \rightarrow tm \rightarrow tm \rightarrow tm.
```

```
Tactic Notation "t_cases" tactic(first) ident(c) :=
  first;
  [ Case_aux c "tvar" | Case_aux c "tapp"
  | Case_aux c "tabs" | Case_aux c "ttrue"
  | Case_aux c "tfalse" | Case_aux c "tif" ].
```

Note that an abstraction  $\xspace x$ : T.t (formally, tabs  $\xspace x$ : T: t) is always annotated with the type T of its parameter, in contrast to Coq (and other functional languages like ML, Haskell, etc.), which use type inference to fill in missing annotations. We're not considering type inference here, to keep things simple.

Some examples...

```
Definition x := (Id 0).
Definition y := (Id 1).
Definition z := (Id 2).
Hint Unfold x.
Hint Unfold y.
Hint Unfold z.
   idB = \x:Bool. \x
Notation idB :=
  (tabs \times TBool (tvar \times)).
   idBB = \x:Bool \rightarrow Bool. \ x
Notation idBB :=
  (tabs \times (TArrow TBool TBool) (tvar \times)).
   idBBBB = \x:(Bool \rightarrow Bool) \rightarrow (Bool \rightarrow Bool). x
Notation idBBBB :=
  (tabs x (TArrow (TArrow TBool TBool)
                           (TArrow TBool TBool))
     (tvar x)).
   k = \x:Bool. \y:Bool. \x
Notation k := (tabs \times TBool (tabs y TBool (tvar x))).
   notB = \x:Bool. if x then false else true
Notation not B := (tabs \times TBool (tif (tvar \times) tfalse ttrue)).
    (We write these as Notations rather than Definitions to make things easier for auto.)
```

## 14.2.3 Operational Semantics

To define the small-step semantics of STLC terms, we begin - as always - by defining the set of values. Next, we define the critical notions of *free variables* and *substitution*, which are used in the reduction rule for application expressions. And finally we give the small-step relation itself.

#### Values

To define the values of the STLC, we have a few cases to consider.

First, for the boolean part of the language, the situation is clear: true and false are the only values. An if expression is never a value.

Second, an application is clearly not a value: It represents a function being invoked on some argument, which clearly still has work left to do.

Third, for abstractions, we have a choice:

- We can say that  $\xspace x: T.t1$  is a value only when t1 is a value i.e., only if the function's body has been reduced (as much as it can be without knowing what argument it is going to be applied to).
- Or we can say that  $\ximes x: T.t1$  is always a value, no matter whether t1 is one or not in other words, we can say that reduction stops at abstractions.

Coq, in its built-in functional programming language, makes the first choice – for example, Eval simpl in (fun x:bool => 3 + 4) yields fun x:bool  $\Rightarrow 7$ .

Most real-world functional programming languages make the second choice – reduction of a function's body only begins when the function is actually applied to an argument. We also make the second choice here.

Finally, having made the choice not to reduce under abstractions, we don't need to worry about whether variables are values, since we'll always be reducing programs "from the outside in," and that means the **step** relation will always be working with closed terms (ones with no free variables).

```
Inductive value : tm \rightarrow Prop := |v_abs : \forall x \ T \ t,
value (tabs x \ T \ t)
| v_true :
value ttrue
| v_false :
value tfalse.
```

Hint Constructors value.

#### Free Variables and Substitution

Now we come to the heart of the STLC: the operation of substituting one term for a variable in another term.

This operation will be used below to define the operational semantics of function application, where we will need to substitute the argument term for the function parameter in the function's body. For example, we reduce (\x:Bool. if x then true else x) false to if false then true else false || by substituting false for the parameter x in the body of the function.

In general, we need to be able to substitute some given term s for occurrences of some variable x in another term t. In informal discussions, this is usually written [x:=s]t and pronounced "substitute x with s in t."

Here are some examples:

```
x:=true (if x then x else false) yields if true then true else false
x:=true x yields true
x:=true (if x then x else y) yields if true then true else y
x:=true y yields y
x:=true false yields false (vacuous substitution)
x:=true (\y:Bool. if y then x else false) yields \y:Bool. if y then true else false
x:=true (\y:Bool. x) yields \y:Bool. true
x:=true (\y:Bool. y) yields \y:Bool. y
x:=true (\x:Bool. x) yields \x:Bool. x
```

The last example is very important: substituting x with true in x:Bool. x:Bool.

```
Here is the definition, informally... x:=sx=s x:=sy=y if x <> y x:=s(\x:T11.t12) = \x:T11. t12 x:=s(\y:T11.t12) = \y:T11. x:=st12 if x <> y x:=s(t1 t2) = (x:=st1) (x:=st2) x:=strue = true x:=sfalse = false x:=s(if t1 then t2 else t3) = if x:=st1 then x:=st2 else x:=st3 ] ... and formally:
```

```
Reserved Notation "'[' x ':=' s ']' t" (at level 20).

Fixpoint subst (x:id) (s:tm) (t:tm): tm:=

match t with

| tvar x' \Rightarrow

if eq_id_dec x x' then s else t

| tabs x' T t1 \Rightarrow

tabs x' T (if eq_id_dec x x' then t1 else ([x:=s] t1))

| tapp t1 t2 \Rightarrow

tapp ([x:=s] t1) ([x:=s] t2)

| ttrue \Rightarrow

ttrue

| tfalse \Rightarrow

tfalse

| tif t1 t2 t3 \Rightarrow
```

Technical note: Substitution becomes trickier to define if we consider the case where s, the term being substituted for a variable in some other term, may itself contain free variables. Since we are only interested here in defining the step relation on closed terms (i.e., terms like \x:Bool. x, that do not mention variables are not bound by some enclosing lambda), we can skip this extra complexity here, but it must be dealt with when formalizing richer languages.

**Exercise:** 3 stars (substi) The definition that we gave above uses Coq's Fixpoint facility to define substitution as a function. Suppose, instead, we wanted to define substitution as an inductive relation substi. We've begun the definition by providing the Inductive header and one of the constructors; your job is to fill in the rest of the constructors.

```
Inductive substi (s:tm) (x:id) : tm \to tm \to Prop := |s\_var1 : substi <math>s \ x (tvar x) s

.

Hint Constructors substi.

Theorem substi_correct : \forall \ s \ x \ t \ t', [x:=s] \ t = t' \leftrightarrow substi \ s \ x \ t \ t'.

Proof.

Admitted.
```

#### Reduction

The small-step reduction relation for STLC now follows the same pattern as the ones we have seen before. Intuitively, to reduce a function application, we first reduce its left-hand side until it becomes a literal function; then we reduce its right-hand side (the argument) until it is also a value; and finally we substitute the argument for the bound variable in the body of the function. This last rule, written informally as (x:T.t12) v2 ==> x:=v2t12 is traditionally called "beta-reduction".

value v2

```
\begin{array}{ll} (\mathrm{ST\_AppAbs}) \ (\backslash \mathrm{x:T.t12}) \ \mathrm{v2} ==> \mathsf{x}{:=}v2\mathrm{t}12 \\ \mathrm{t1} ==> \mathrm{t1'} \end{array}
```

```
(ST\_App1) t1 t2 ==> t1' t2
   value v1 t2 ==> t2
(ST\_App2) v1 t2 ==> v1 t2' ... plus the usual rules for booleans:
(ST_IfTrue) (if true then t1 else t2) ==> t1
(ST_IFFalse) (if false then t1 else t2) ==> t2
   t1 ==> t1'
(ST_If) (if t1 then t2 else t3) ==> (if t1' then t2 else t3)
Reserved Notation "t1'==>' t2" (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_AppAbs : \forall x T t12 v2,
           value v2 \rightarrow
           (tapp (tabs x \ T \ t12) \ v2) ==> [x := v2] t12
  | ST\_App1 : \forall t1 t1' t2,
           t1 ==> t1' \rightarrow
           tapp t1 t2 ==> tapp <math>t1, t2
  | ST\_App2 : \forall v1 t2 t2',
          value v1 \rightarrow
           t2 ==> t2' \rightarrow
           tapp v1 t2 ==> tapp <math>v1 t2'
  | ST_IfTrue : \forall t1 t2,
       (tif ttrue t1 t2) ==> t1
  | ST_IfFalse : \forall t1 t2,
       (tif tfalse t1 t2) ==> t2
  | ST_If : \forall t1 t1' t2 t3,
       t1 ==> t1' \rightarrow
       (tif t1 t2 t3) ==> (tif t1' t2 t3)
where "t1 '==>' t2" := (step t1 \ t2).
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first;
  [ Case_aux c "ST_AppAbs" | Case_aux c "ST_App1"
   Case_aux c "ST_App2" | Case_aux c "ST_IfTrue"
  | Case_aux c "ST_IfFalse" | Case_aux c "ST_If" ].
Hint Constructors step.
Notation multistep := (multi step).
Notation "t1'==>*' t2" := (multistep t1 t2) (at level 40).
```

### Examples

```

   A more automatic proof
Lemma step_example1':
  (tapp idBB idB) ==>* idB.
Proof. normalize. Qed.
   Again, we can use the normalize tactic from above to simplify the proof.
Lemma step_example2':
  (tapp idBB (tapp idBB idB)) ==>* idB.
Proof.
  normalize.
Qed.
Lemma step_example3':
  tapp (tapp idBB notB) ttrue ==>* tfalse.
Proof. normalize. Qed.
Lemma step_example4':
  tapp idBB (tapp notB ttrue) ==>* tfalse.
Proof. normalize. Qed.
Exercise: 2 stars (step_example3) Try to do this one both with and without normal-
ize.
Lemma step_example5:
        (tapp (tapp idBBBB idBB) idB)
  ==>* idB.
Proof.
   Admitted.
```

## 14.2.4 Typing

#### Contexts

Question: What is the type of the term "x y"?

Answer: It depends on the types of x and y!

I.e., in order to assign a type to a term, we need to know what assumptions we should make about the types of its free variables.

This leads us to a three-place "typing judgment", informally written  $Gamma \vdash t : T$ , where Gamma is a "typing context" – a mapping from variables to their types.

We hide the definition of partial maps in a module since it is actually defined in SfLib.

```
Module PARTIALMAP.
```

```
Definition partial_map (A:Type) := id \rightarrow option A.
Definition empty \{A:Type\} : partial_map A := (fun <math>\_ \Rightarrow None).
```

Informally, we'll write Gamma, x: T for "extend the partial function Gamma to also map x to T." Formally, we use the function extend to add a binding to a partial map.

```
Definition extend \{A: \text{Type}\}\ (Gamma: \text{partial\_map }A)\ (x:\text{id})\ (T:A):= \text{fun }x'\Rightarrow \text{if eq\_id\_dec }x\ x' \text{ then Some }T \text{ else }Gamma\ x'.

Lemma extend\_eq: \forall\ A\ (ctxt: \text{partial\_map }A)\ x\ T, (extend ctxt\ x\ T)\ x=\text{Some }T.

Proof.

intros. unfold extend. rewrite eq_id. auto.

Qed.

Lemma extend_neq: \forall\ A\ (ctxt: \text{partial\_map }A)\ x1\ T\ x2, x2\neq x1\to (extend ctxt\ x2\ T)\ x1=ctxt\ x1.

Proof.

intros. unfold extend. rewrite neq\_id; auto.

Qed.

End PartialMap.
```

#### Typing Relation

Definition context := partial\_map ty.

Gamma x = T

```
(T_Var) Gamma |- x \in T
Gamma , x:T11 |- t12 \in T12

(T_Abs) Gamma |- \x:T11.t12 \in T11->T12
Gamma |- t1 \in T11->T12 Gamma |- t2 \in T11

(T_App) Gamma |- t1 t2 \in T12

(T_True) Gamma |- true \in Bool
```

```
(T_False)
 Gamma |- false \in Bool
 Gamma |- t1 \in Bool
 Gamma |- t2 \in T
 Gamma |- t3 \in T
```

 $(T_If)$  Gamma |- if t1 then t2 else t3 \in T

```
We can read the three-place relation Gamma \vdash t \setminus in T as: "to the term t we can
assign the type T using as types for the free variables of t the ones specified in the context
Gamma."
Reserved Notation "Gamma '-' t '\in' T" (at level 40).
Inductive has\_type: context \rightarrow tm \rightarrow ty \rightarrow Prop :=
   | \mathsf{T}_{\mathsf{-}}\mathsf{Var} : \forall \ Gamma \ x \ T,
          Gamma \ x = Some \ T \rightarrow
          Gamma \vdash \mathsf{tvar}\ x \setminus \mathsf{in}\ T
   \mid \mathsf{T}_{-}\mathsf{Abs} : \forall \ Gamma \ x \ T11 \ T12 \ t12,
          extend Gamma \ x \ T11 \vdash t12 \setminus in \ T12 \rightarrow
          Gamma \vdash \mathsf{tabs} \ x \ T11 \ t12 \setminus \mathsf{in} \ \mathsf{TArrow} \ T11 \ T12
   \mid \mathsf{T}_{-}\mathsf{App} : \forall T11 \ T12 \ Gamma \ t1 \ t2,
          Gamma \vdash t1 \setminus in TArrow T11 T12 \rightarrow
          Gamma \vdash t2 \setminus in T11 \rightarrow
          Gamma \vdash \mathsf{tapp}\ t1\ t2 \setminus \mathsf{in}\ T12
   | \mathsf{T}_{\mathsf{-}}\mathsf{True} : \forall \mathsf{Gamma},
            Gamma \vdash \mathsf{ttrue} \setminus \mathsf{in} \mathsf{TBool}
   | T_False : \forall Gamma,
            Gamma \vdash \mathsf{tfalse} \setminus \mathsf{in} \mathsf{TBool}
   \mid \mathsf{T}_{\mathsf{-}}\mathsf{lf} : \forall t1 \ t2 \ t3 \ T \ Gamma,
            Gamma \vdash t1 \setminus in TBool \rightarrow
            Gamma \vdash t2 \setminus in T \rightarrow
            Gamma \vdash t3 \setminus in T \rightarrow
            Gamma \vdash \mathsf{tif}\ t1\ t2\ t3 \setminus \mathsf{in}\ T
where "Gamma '|-' t '\in' T" := (has_type Gamma\ t\ T).
Tactic Notation "has_type_cases" tactic(first) ident(c) :=
   first;
   [Case\_aux\ c\ "T\_Var"\ |\ Case\_aux\ c\ "T\_Abs"]
     Case\_aux \ c \ "T\_App" \mid Case\_aux \ c \ "T\_True"
    Case\_aux \ c \ "T\_False" \mid Case\_aux \ c \ "T\_If" ].
Hint Constructors has_type.
```

#### Examples

```
Example typing_example_1 : empty \vdash tabs x TBool (tvar x) \in TArrow TBool TBool.
```

```
apply T_Abs. apply T_Var. reflexivity. Qed.
   Note that since we added the has_type constructors to the hints database, auto can
actually solve this one immediately.
Example typing_example_1':
  empty \vdash tabs x TBool (tvar x) \in TArrow TBool TBool.
Proof. auto. Qed.
   Another example: empty |-\rangle x:A. \ y:A->A. \ y(y(x)) \in A->A.
Example typing_example_2 :
  empty ⊢
    (tabs x TBool
       (tabs y (TArrow TBool TBool)
          (tapp (tvar y) (tapp (tvar y) (tvar x)))) \in
    (TArrow TBool (TArrow (TArrow TBool TBool)).
Proof with auto using extend_eq.
  apply T_Abs.
  apply T_Abs.
  eapply T_App. apply T_Var...
  eapply T_App. apply T_Var...
  apply T_Var...
Qed.
Exercise: 2 stars, optional (typing_example_2_full) Prove the same result without
using auto, eauto, or eapply.
Example typing_example_2_full:
  empty ⊢
    (tabs x TBool
       (tabs y (TArrow TBool TBool)
          (tapp (tvar y) (tapp (tvar y) (tvar x)))) \in
    (TArrow TBool (TArrow (TArrow TBool TBool)).
Proof.
   Admitted.
   Exercise: 2 stars (typing_example_3) Formally prove the following typing derivation
holds:
   empty |- \x:Bool->B. \y:Bool->Bool. \z:Bool. y (x z) \in T.
Example typing_example_3 :
  \exists T.
    empty ⊢
```

Proof.

```
(tabs x (TArrow TBool TBool)
          (tabs y (TArrow TBool TBool)
              (tabs z TBool
                 (tapp (tvar y) (tapp (tvar x) (tvar z))))) \in
       T.
Proof with auto.
   Admitted.
   We can also show that terms are not typable. For example, let's formally check that
there is no typing derivation assigning a type to the term \x:Bool. \y:Bool, x y - i.e., ~ exists
T, empty |-\rangle x:Bool. \ \ y:Bool, \ x \ y : T.
Example typing_nonexample_1:
  \neg \exists T,
      empty ⊢
         (tabs x TBool
              (tabs y TBool
                 (tapp (tvar x) (tvar y)))) \in
         T.
Proof.
  intros Hc. inversion Hc.
  inversion H. subst. clear H.
  inversion H5. subst. clear H5.
  inversion H4. subst. clear H4.
  inversion H2. subst. clear H2.
  inversion H5. subst. clear H5.
  inversion H1. Qed.
Exercise: 3 stars, optional (typing_nonexample_3) Another nonexample: ~ (exists
S, exists T, empty |-\rangle x:S. x x : T).
Example typing_nonexample_3:
  \neg (\exists S, \exists T,
         empty ⊢
           (tabs \times S
               (tapp (tvar x) (tvar x))) \in
           T).
Proof.
   Admitted.
   End STLC.
```

# Chapter 15

# Library Types

# 15.1 Types: Type Systems

Require Export Smallstep.

Hint Constructors multi.

Our next major topic is type systems – static program analyses that classify expressions according to the "shapes" of their results. We'll begin with a typed version of a very simple language with just booleans and numbers, to introduce the basic ideas of types, typing rules, and the fundamental theorems about type systems: type preservation and progress. Then we'll move on to the simply typed lambda-calculus, which lives at the core of every modern functional programming language (including Coq).

# 15.2 Typed Arithmetic Expressions

To motivate the discussion of type systems, let's begin as usual with an extremely simple toy language. We want it to have the potential for programs "going wrong" because of runtime type errors, so we need something a tiny bit more complex than the language of constants and addition that we used in chapter Smallstep: a single kind of data (just numbers) is too simple, but just two kinds (numbers and booleans) already gives us enough material to tell an interesting story.

The language definition is completely routine. The only thing to notice is that we are not using the asnum/aslist trick that we used in chapter HoareList to make all the operations total by forcibly coercing the arguments to + (for example) into numbers. Instead, we simply let terms get stuck if they try to use an operator with the wrong kind of operands: the **step** relation doesn't relate them to anything.

## 15.2.1 Syntax

Informally:  $t := true \mid false \mid if t then t else t \mid 0 \mid succ t \mid pred t \mid iszero t Formally:$ 

```
Inductive tm : Type :=
  ttrue : tm
   tfalse : tm
   \mathsf{tif}: \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}
   tzero : tm
   tsucc: tm \rightarrow tm
   \mathsf{tpred}:\mathsf{tm}\to\mathsf{tm}
   tiszero : tm \rightarrow tm.
    Values are true, false, and numeric values...
Inductive bvalue: tm \rightarrow Prop :=
   bv_true : bvalue ttrue
  | bv_false : bvalue tfalse.
Inductive nvalue: tm \rightarrow Prop :=
   nv_zero : nvalue tzero
  | nv_succ : \forall t, nvalue t \rightarrow nvalue (tsucc t).
Definition value (t:tm) := bvalue \ t \lor nvalue \ t.
Hint Constructors bvalue nvalue.
Hint Unfold value.
Hint Unfold extend.
            Operational Semantics
15.2.2
Informally:
(ST_IfTrue) if true then t1 else t2 ==> t1
(ST_IfFalse) if false then t1 else t2 ==> t2
   t1 ==> t1'
(ST_If) if t1 then t2 else t3 ==> if t1' then t2 else t3
   t1 ==> t1'
(ST\_Succ) succ t1 ==> succ t1'
(ST_PredZero) \text{ pred } 0 ==> 0
   numeric value v1
(ST\_PredSucc) pred (succ v1) ==> v1
   t1 ==> t1'
```

 $(ST\_Pred)$  pred t1 ==> pred t1'

```
(ST_IszeroZero) iszero 0 ==> true
    numeric value v1
(ST_IszeroSucc) iszero (succ v1) ==> false
    t1 ==> t1'
(ST_Iszero) iszero t1 ==> iszero t1
    Formally:
Reserved Notation "t1 '==>' t2" (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  \mid \mathsf{ST\_IfTrue} : \forall t1 \ t2,
        (tif ttrue t1 t2) ==> t1
  | ST_IfFalse : \forall t1 t2,
        (tif tfalse t1 t2) ==> t2
  \mid ST_If : \forall t1 t1' t2 t3,
       t1 ==> t1' \rightarrow
        (tif t1 t2 t3) ==> (tif t1' t2 t3)
  | ST_Succ : \forall t1 t1',
       t1 ==> t1' \rightarrow
        (tsucc t1) ==> (tsucc t1')

        (tpred tzero) ==> tzero
  | ST_PredSucc : \forall t1,
       nvalue t1 \rightarrow
        (tpred (tsucc t1)) ==> t1
  | ST_Pred : \forall t1 t1',
       t1 ==> t1' \rightarrow
        (tpred t1) ==> (tpred t1')
  | ST_IszeroZero :
        (tiszero tzero) ==> ttrue
  | ST_IszeroSucc : \forall t1,
         nvalue t1 \rightarrow
        (tiszero (tsucc t1)) ==> tfalse
  | ST_Iszero : \forall t1 t1',
       t1 ==> t1' \rightarrow
        (tiszero t1) ==> (tiszero t1')
where "t1 '==>' t2" := (step t1 \ t2).
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first;
  | Case_aux c "ST_IfTrue" | Case_aux c "ST_IfFalse" | Case_aux c "ST_If"
```

```
| Case_aux c "ST_Succ" | Case_aux c "ST_PredZero" | Case_aux c "ST_PredSucc" | Case_aux c "ST_Pred" | Case_aux c "ST_IszeroZero" | Case_aux c "ST_IszeroSucc" | Case_aux c "ST_Iszero" |.
```

#### Hint Constructors step.

Notice that the **step** relation doesn't care about whether expressions make global sense – it just checks that the operation in the *next* reduction step is being applied to the right kinds of operands.

For example, the term *succ* true (i.e., tsucc ttrue in the formal syntax) cannot take a step, but the almost as obviously nonsensical term succ (if true then true else true) can take a step (once, before becoming stuck).

#### 15.2.3 Normal Forms and Values

The first interesting thing about the **step** relation in this language is that the strong progress theorem from the Smallstep chapter fails! That is, there are terms that are normal forms (they can't take a step) but not values (because we have not included them in our definition of possible "results of evaluation"). Such terms are *stuck*.

```
Notation step_normal_form := (normal_form step).

Definition stuck (t:tm) : Prop := step_normal_form t ∧ ¬ value t.

Hint Unfold stuck.

Exercise: 2 stars (some_term_is_stuck)   Example some_term_is_stuck : ∃ t, stuck t.

Proof.

Admitted.
```

However, although values and normal forms are not the same in this language, the former set is included in the latter. This is important because it shows we did not accidentally define things so that some value could still take a step.

Exercise: 3 stars, advanced (value\_is\_nf) Hint: You will reach a point in this proof where you need to use an induction to reason about a term that is known to be a numeric value. This induction can be performed either over the term itself or over the evidence that it is a numeric value. The proof goes through in either case, but you will find that one way is quite a bit shorter than the other. For the sake of the exercise, try to complete the proof both ways.

```
Lemma value_is_nf : \forall t, value t \rightarrow \text{step\_normal\_form } t. Proof.
```

 $\begin{array}{c} Admitted. \\ \square \end{array}$ 

Exercise: 3 stars, optional (step\_deterministic) Using value\_is\_nf, we can show that the step relation is also deterministic...

```
Theorem step_deterministic:
    deterministic step.

Proof with eauto.

Admitted.
```

### 15.2.4 **Typing**

The next critical observation about this language is that, although there are stuck terms, they are all "nonsensical", mixing booleans and numbers in a way that we don't even want to have a meaning. We can easily exclude such ill-typed terms by defining a typing relation that relates terms to the types (either numeric or boolean) of their final results.

```
Inductive ty : Type :=
    | TBool : ty
    | TNat : ty.
```

In informal notation, the typing relation is often written  $\vdash t \setminus \text{in } T$ , pronounced "t has type T." The  $\vdash$  symbol is called a "turnstile". (Below, we're going to see richer typing relations where an additional "context" argument is written to the left of the turnstile. Here, the context is always empty.)

```
Reserved Notation "'|-' t '\in' T" (at level 40).
Inductive has_type : tm \rightarrow ty \rightarrow Prop :=
          | T_True :
                                    ⊢ ttrue \in TBool
          | T_False :
                                    ⊢ tfalse \in TBool
          \mid \mathsf{T_If} : \forall t1 \ t2 \ t3 \ T
                                    \vdash t1 \setminus in TBool \rightarrow
                                    \vdash t2 \setminus in T \rightarrow
                                    \vdash t3 \setminus in T \rightarrow
                                    \vdash tif t1 t2 t3 \setminus in T
          |T_Zero:
                                    ⊢ tzero \in TNat
          | \mathsf{T}_{\mathsf{-}}\mathsf{Succ} : \forall t1,
                                    \vdash t1 \setminus in TNat \rightarrow
                                    \vdash tsucc t1 \setminus in TNat
          \mid \mathsf{T}_{\mathsf{-}}\mathsf{Pred} : \forall t1,
                                    \vdash t1 \setminus in TNat \rightarrow
                                    \vdash tpred t1 \setminus in TNat
          |\mathsf{T}_{\mathsf{L}}| | \mathsf{T}_{\mathsf{L}} | \mathsf{T}_{\mathsf{L}
                                    \vdash t1 \setminus in TNat \rightarrow
                                    \vdash tiszero t1 \setminus in TBool
where "'-' t '\in' T" := (has_type t T).
Tactic Notation "has_type_cases" tactic(first) ident(c) :=
          first;
          [ Case_aux c "T_True" | Case_aux c "T_False" | Case_aux c "T_If"
                Case_aux c "T_Zero" | Case_aux c "T_Succ" | Case_aux c "T_Pred"
           | Case\_aux \ c \ "T\_Iszero" |.
Hint Constructors has_type.
Examples
It's important to realize that the typing relation is a conservative (or static) approximation:
it does not calculate the type of the normal form of a term.
Example has_type_1:
         ⊢ tif tfalse tzero (tsucc tzero) \in TNat.
Proof.
          apply T_lf.
```

apply T\_False. apply T\_Zero. apply T\_Succ.

```
apply T_Zero.

Qed.

(Since we've included all the constructors of the typing relation in the hint database, the auto tactic can actually find this proof automatically.)

Example has_type_not:

¬ (⊢ tif tfalse tzero ttrue \in TBool).

Proof.
```

intros Contra. solve by inversion 2. Qed.

Exercise: 1 star, optional (succ\_hastype\_nat\_hastype\_nat) Example succ\_hastype\_nat\_hastype :  $\forall t$ ,  $\vdash$  tsucc  $t \in TN$ 

```
\vdash tsucc t \in TNat \rightarrow t \in TNat.

Proof.

Admitted.
```

### 15.2.5 Progress

The typing relation enjoys two critical properties. The first is that well-typed normal forms are values (i.e., not stuck).

```
Theorem progress : \forall t \ T, \vdash t \setminus \text{in } T \rightarrow \text{value } t \vee \exists t', t ==> t'.
```

Exercise: 3 stars (finish\_progress) Complete the formal proof of the progress property. (Make sure you understand the informal proof fragment in the following exercise before starting – this will save you a lot of time.)

```
Proof with auto.
```

```
intros t T HT.

has\_type\_cases (induction HT) Case...

Case "T_If".

right. inversion IHHT1; clear IHHT1.

SCase "t1 is a value". inversion H; clear H.

SSCase "t1 is a bvalue". inversion H0; clear H0.

SSSCase "t1 is ttrue".

\exists t2...

SSSCase "t1 is tfalse".

\exists t3...

SSCase "t1 is an nvalue".

solve by inversion 2. SCase "t1 can take a step".
```

```
inversion H as [t1' H1]. \exists (tif t1' t2 t3)... Admitted.
```

Exercise: 3 stars, advanced (finish\_progress\_informal) Complete the corresponding informal proof:

Theorem: If  $\vdash t \setminus \text{in } T$ , then either t is a value or else t ==> t' for some t'. Proof: By induction on a derivation of  $\vdash t \setminus \text{in } T$ .

- If the last rule in the derivation is T\_If, then t = if t1 then t2 else t3, with  $\vdash t1$  \in Bool,  $\vdash t2$  \in T and  $\vdash t3$  \in T. By the IH, either t1 is a value or else t1 can step to some t1.
  - If t1 is a value, then it is either an **nvalue** or a **bvalue**. But it cannot be an **nvalue**, because we know  $\vdash t1$  \in Bool and there are no rules assigning type Bool to any term that could be an **nvalue**. So t1 is a **bvalue** i.e., it is either true or false. If t1 = true, then t steps to t2 by ST\_IfTrue, while if t1 = false, then t steps to t3 by ST\_IfFalse. Either way, t can step, which is what we wanted to show.
  - If t1 itself can take a step, then, by  $ST_{-}If$ , so can t.

This is more interesting than the strong progress theorem that we saw in the Smallstep chapter, where *all* normal forms were values. Here, a term can be stuck, but only if it is ill typed.

Exercise: 1 star (step\_review) Quick review. Answer true or false. In this language...

- Every well-typed normal form is a value.
- Every value is a normal form.

- The single-step evaluation relation is a partial function (i.e., it is deterministic).
- The single-step evaluation relation is a *total* function.

\_\_\_

### 15.2.6 Type Preservation

The second critical property of typing is that, when a well-typed term takes a step, the result is also a well-typed term.

This theorem is often called the *subject reduction* property, because it tells us what happens when the "subject" of the typing relation is reduced. This terminology comes from thinking of typing statements as sentences, where the term is the subject and the type is the predicate.

```
Theorem preservation : \forall \ t \ t' \ T, \vdash t \setminus \text{in } T \rightarrow t => t' \rightarrow \vdash t' \setminus \text{in } T.
```

Exercise: 2 stars (finish\_preservation) Complete the formal proof of the preservation property. (Again, make sure you understand the informal proof fragment in the following exercise first.)

```
Proof with auto.

intros t t' T HT HE.

generalize dependent t'.

has_type_cases (induction HT) Case;

intros t' HE;

try (solve by inversion).

Case "T_If". inversion HE; subst.

SCase "ST_IFTrue". assumption.

SCase "ST_IfFalse". assumption.

SCase "ST_If". apply T_If; try assumption.

apply IHHT1; assumption.

Admitted.
```

Exercise: 3 stars, advanced (finish\_preservation\_informal) Complete the following proof:

```
Theorem: If \vdash t \mid \text{in } T \text{ and } t ==> t', then \vdash t' \mid \text{in } T. Proof: By induction on a derivation of \vdash t \mid \text{in } T.
```

• If the last rule in the derivation is T\_lf, then t = if t1 then t2 else t3, with  $\vdash t1 \setminus \text{in Bool}$ ,  $\vdash t2 \setminus \text{in } T$  and  $\vdash t3 \setminus \text{in } T$ .

Inspecting the rules for the small-step reduction relation and remembering that t has the form if ..., we see that the only ones that could have been used to prove t ==> t are  $ST_IfTrue$ ,  $ST_IfFalse$ , or  $ST_If$ .

- If the last rule was ST\_lfTrue, then t' = t2. But we know that  $\vdash t2 \setminus T$ , so we are done.
- If the last rule was ST\_IfFalse, then t' = t3. But we know that  $\vdash t3 \setminus T$ , so we are done.
- If the last rule was ST\_If, then t' = if t1' then t2 else t3, where t1 ==> t1'. We know  $\vdash t1$  \in Bool so, by the IH,  $\vdash t1'$  \in Bool. The T\_If rule then gives us  $\vdash$  if t1' then t2 else t3 \in T, as required.

**Exercise:** 3 stars (preservation\_alternate\_proof) Now prove the same property again by induction on the *evaluation* derivation instead of on the typing derivation. Begin by carefully reading and thinking about the first few lines of the above proof to make sure you understand what each one is doing. The set-up for this proof is similar, but not exactly the same.

```
Theorem preservation': \forall \ t \ t' T, \vdash t \setminus \text{in } T \rightarrow t => t' \rightarrow \vdash t' \setminus \text{in } T.

Proof with eauto.

Admitted.
```

### 15.3 Aside: the *normalize* Tactic

When experimenting with definitions of programming languages in Coq, we often want to see what a particular concrete term steps to – i.e., we want to find proofs for goals of the form  $t ==>^* t'$ , where t is a completely concrete term and t' is unknown. These proofs are simple but repetitive to do by hand. Consider for example reducing an arithmetic expression using the small-step relation **astep**.

```
Definition amultistep st := \text{multi} (astep st). Notation " t '/' st '==>a*' t' " := (amultistep st t t') (at level 40, st at level 39). Example astep_example1 : (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state ==>a× (ANum 15). Proof. apply multi_step with (APlus (ANum 3) (ANum 12)). apply AS_Plus2. apply av_num.
```

```
apply AS_Mult.

apply multi_step with (ANum 15).

apply AS_Plus.

apply multi_refl.

Qed.
```

We repeatedly apply multi\_step until we get to a normal form. The proofs that the intermediate steps are possible are simple enough that auto, with appropriate hints, can solve them.

```
Hint Constructors astep aval.
Example astep_example1':
   (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state
==>a× (ANum 15).
Proof.
   eapply multi_step. auto. simpl.
   eapply multi_step. auto. simpl.
   apply multi_refl.
Qed.
```

The following custom Tactic Notation definition captures this pattern. In addition, before each multi\_step we print out the current goal, so that the user can follow how the term is being evaluated.

```
Tactic Notation "print_goal" := match goal with \vdash ?x \Rightarrow idtac \ x \ end. Tactic Notation "normalize" := repeat (print\_goal; eapply multi\_step ; [ (eauto \ 10; fail) \mid (instantiate; simpl)]); apply multi\_refl. Example astep_example1" : (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state ==>a\times (ANum 15). Proof. normalize. Qed.
```

The *normalize* tactic also provides a simple way to calculate what the normal form of a term is, by proving a goal with an existential variable in it.

```
Example astep_example1''' : ∃ e',
   (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state
   ==>a× e'.
Proof.
   eapply ex_intro. normalize.

Qed.
```

```
Exercise: 1 star (normalize_ex) Theorem normalize_ex: \exists e',

(AMult (ANum 3) (AMult (ANum 2) (ANum 1))) / empty_state

==>a× e'.

Proof.

Admitted.

Exercise: 1 star, optional (normalize_ex') For comparison, prove it using apply instead of eapply.

Theorem normalize_ex': \exists e',

(AMult (ANum 3) (AMult (ANum 2) (ANum 1))) / empty_state

==>a× e'.
```

 $\begin{array}{c} {\tt Proof.} \\ {\tt Admitted.} \end{array}$ 

### 15.3.1 Type Soundness

Putting progress and preservation together, we can see that a well-typed term can *never* reach a stuck state.

```
Definition multistep := (multi step). Notation "t1'==>*' t2" := (multistep t1\ t2) (at level 40). Corollary soundness : \forall\ t\ t'\ T, \vdash\ t \ \text{in}\ T \to t ==>*\ t' \to \text{``(stuck }t').} Proof. intros t\ t'\ T\ HT\ P. induction P; intros [R\ S]. destruct (progress x\ T\ HT); auto. apply IHP. apply (preservation x\ y\ T\ HT\ H). unfold stuck. split; auto. Qed.
```

#### 15.3.2 Additional Exercises

**Exercise: 2 stars (subject\_expansion)** Having seen the subject reduction property, it is reasonable to wonder whether the opposity property – subject *expansion* – also holds. That is, is it always the case that, if t ==> t' and  $\vdash t' \setminus \text{in } T$ , then  $\vdash t \setminus \text{in } T$ ? If so, prove it. If not, give a counter-example. (You do not need to prove your counter-example in Coq, but feel free to do so if you like.)

**Exercise: 2 stars (variation1)** Suppose, that we add this new rule to the typing relation:  $|T\_SuccBool: forall t, |-t \in TBool->|-tsucct \in TBool Which of the following properties remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.$ 

"becomes false." If a property becomes false, give a counterexample.
• Determinism of <b>step</b>
• Progress
• Preservation
Exercise: 2 stars (variation2) Suppose, instead, that we add this new rule to the step relation: $  ST_Funny1 :$ for all t2 t3, (tif ttrue t2 t3) ==> t3 Which of the above properties become false in the presence of this rule? For each one that does, give a counter-example.
Exercise: 2 stars, optional (variation3) Suppose instead that we add this rule: $ $ ST_Funny2: forall t1 t2 t2' t3, t2 ==> t2' -> (tif t1 t2 t3) ==> (tif t1 t2' t3) Which of the above properties become false in the presence of this rule? For each one that does, give a counter-example. $\Box$
Exercise: 2 stars, optional (variation4) Suppose instead that we add this rule: $ST_Funny3$ : (tpred tfalse) ==> (tpred (tpred tfalse)) Which of the above properties become false in the presence of this rule? For each one that does, give a counter-example.
Exercise: 2 stars, optional (variation5) Suppose instead that we add this rule:   T_Funny4 :  - tzero \in TBool  ] Which of the above properties become false in the presence of this rule? For each one that does, give a counter-example.
Exercise: 2 stars, optional (variation6) Suppose instead that we add this rule:    T_Funny5 :  - tpred tzero \in TBool ]] Which of the above properties become false in the presence of this rule? For each one that does, give a counter-example.
Exercise: 3 stars, optional (more_variations) Make up some exercises of your own along the same lines as the ones above. Try to find ways of selectively breaking properties $-$ i.e., ways of changing the definitions that break just one of the properties and leave the others alone. $\square$

**Exercise:** 1 star (remove\_predzero) The evaluation rule  $E_{-}PredZero$  is a bit counterintuitive: we might feel that it makes more sense for the predecessor of zero to be undefined, rather than being defined to be zero. Can we achieve this simply by removing the rule from the definition of **step**? Would doing so create any problems elsewhere?

Exercise: 4 stars, advanced (prog\_pres\_bigstep) Suppose our evaluation relation is defined in the big-step style. What are the appropriate analogs of the progress and preservation properties?

# Chapter 16

# Library Auto

### 16.1 Auto: More Automation

Require Export Imp.

Up to now, we've continued to use a quite restricted set of Coq's tactic facilities. In this chapter, we'll learn more about two very powerful features of Coq's tactic language: proof search via the auto and eauto tactics, and automated forward reasoning via the Ltac hypothesis matching machinery. Using these features together with Ltac's scripting facilities will enable us to make our proofs startlingly short! Used properly, they can also make proofs more maintainable and robust in the face of incremental changes to underlying definitions.

There's a third major source of automation we haven't fully studied yet, namely builtin decision procedures for specific kinds of problems: omega is one example, but there are others. This topic will be deferred for a while longer.

Our motivating example will be this proof, repeated with just a few small changes from lmp. We will try to simplify this proof in several stages.

```
Ltac inv\ H:= inversion H; subst; clear H. Theorem ceval_deterministic: \forall\ c\ st\ st1\ st2, c\ /\ st\ |\ st1\ \to c\ /\ st\ |\ st2\ \to st1=st2. Proof.

intros c\ st\ st1\ st2\ E1\ E2; generalize dependent st2; ceval_cases (induction E1) Case; intros st2\ E2; inv\ E2. Case\ "E_Skip".\ reflexivity. Case\ "E_Ass".\ reflexivity. Case\ "E_Seq". assert (st'=st'0) as EQ1.
```

```
SCase "Proof of assertion". apply IHE1_1; assumption.
  subst st'0.
  apply IHE1_2. assumption.
Case "E_IfTrue".
  SCase "b evaluates to true".
    apply IHE1. assumption.
  SCase "b evaluates to false (contradiction)".
    rewrite H in H5. inversion H5.
Case "E_IfFalse".
  SCase "b evaluates to true (contradiction)".
    rewrite H in H5. inversion H5.
  SCase "b evaluates to false".
    apply IHE1. assumption.
Case "E_WhileEnd".
  SCase "b evaluates to false".
    reflexivity.
  SCase "b evaluates to true (contradiction)".
    rewrite H in H2. inversion H2.
Case "E_WhileLoop".
  SCase "b evaluates to false (contradiction)".
    rewrite H in H4. inversion H4.
  SCase "b evaluates to true".
    assert (st' = st'\theta) as EQ1.
      SSCase "Proof of assertion". apply IHE1_1; assumption.
    subst st'0.
    apply IHE1_2. assumption. Qed.
```

### 16.2 The auto and eauto tactics

Thus far, we have (nearly) always written proof scripts that apply relevant hypothoses or lemmas by name. In particular, when a chain of hypothesis applications is needed, we have specified them explicitly. (The only exceptions introduced so far are using assumption to find a matching unqualified hypothesis or (e)constructor to find a matching constructor.)

```
\begin{split} & \texttt{Example auto\_example\_1}: \ \forall \ (P \ Q \ R : \texttt{Prop}), \ (P \to Q) \to (Q \to R) \to P \to R. \\ & \texttt{Proof.} \\ & \texttt{intros} \ P \ Q \ R \ H1 \ H2 \ H3. \\ & \texttt{apply} \ H2. \ \texttt{apply} \ H1. \ \texttt{assumption.} \\ & \texttt{Qed.} \end{split}
```

The auto tactic frees us from this drudgery by searching for a sequence of applications that will prove the goal

Example auto\_example\_1':  $\forall (P \ Q \ R: \texttt{Prop}), (P \to Q) \to (Q \to R) \to P \to R.$ 

Proof.

intros P Q R H1 H2 H3. auto.

Qed.

The auto tactic solves goals that are solvable by any combination of

- intros,
- apply (with a local hypothesis, by default).

The eauto tactic works just like auto, except that it uses eapply instead of apply. Using auto is always "safe" in the sense that it will never fail and will never change the proof state: either it completely solves the current goal, or it does nothing.

A more complicated example:

Example auto\_example\_2 :  $\forall P Q R S T U$  : Prop,

$$\begin{array}{l} (P \rightarrow Q) \rightarrow \\ (P \rightarrow R) \rightarrow \\ (T \rightarrow R) \rightarrow \\ (S \rightarrow T \rightarrow U) \rightarrow \\ ((P \rightarrow Q) \rightarrow (P \rightarrow S)) \rightarrow \\ T \rightarrow \\ P \rightarrow \\ U. \end{array}$$

Proof. auto. Qed.

Search can take an arbitrarily long time, so there are limits to how far auto will search by default

```
\begin{split} \texttt{Example auto\_example\_3}: \, \forall \; (P \; Q \; R \; S \; T \; U \text{: Prop}), \\ (P \to Q) \to (Q \to R) \to (R \to S) \to \\ (S \to T) \to (T \to U) \to P \to U. \end{split}
```

Proof.

auto. auto 6. Qed.

When searching for potential proofs of the current goal, auto and eauto consider the hypotheses in the current context together with a *hint database* of other lemmas and constructors. Some of the lemmas and constructors we've already seen – e.g., eq\_refl, conj, or\_introl, and or\_intror – are installed in this hint database by default.

Example auto\_example\_4 :  $\forall P \ Q \ R$  : Prop,

$$\begin{array}{c} Q \to \\ (Q \to R) \to \\ P \lor (Q \land R). \end{array}$$

Proof.

auto. Qed.

If we want to see which facts auto is using, we can use *info\_auto* instead.

```
Example auto_example_5: 2 = 2.
Proof.
  info_auto. Qed.
  We can extend the hint database just for the purposes of one a
```

We can extend the hint database just for the purposes of one application of auto or eauto by writing auto using ....

```
Lemma le_antisym : \forall \ n \ m: \operatorname{nat}, \ (n \leq m \land m \leq n) \to n = m. Proof. intros. omega. Qed. 
 Example auto_example_6 : \forall \ n \ m \ p : \operatorname{nat}, \ (n \leq p \to (n \leq m \land m \leq n)) \to n \leq p \to n = m. 
 Proof. intros. auto. auto using le_antisym. Qed.
```

Of course, in any given development there will also be some of our own specific constructors and lemmas that are used very often in proofs. We can add these to the global hint database by writing Hint Resolve T. at the top level, where T is a top-level theorem or a constructor of an inductively defined proposition (i.e., anything whose type is an implication). As a shorthand, we can write Hint Constructors c. to tell Coq to do a Hint Resolve for all of the constructors from the inductive definition of c.

It is also sometimes necessary to add Hint Unfold d. where  $\mathsf{d}$  is a defined symbol, so that auto knows to expand uses of  $\mathsf{d}$  and enable further possibilities for applying lemmas that it knows about.

Hint Resolve le\_antisym.

```
Example auto_example_6': \forall n \ m \ p: nat, (n \leq p \to (n \leq m \land m \leq n)) \to n \leq p \to n = m. Proof. intros. auto. Qed. Definition is_fortytwo x := x = 42. Example auto_example_7: \forall x, (x \leq 42 \land 42 \leq x) \to \text{is_fortytwo } x. Proof. auto. Abort. Hint Unfold is_fortytwo. Example auto_example_7': \forall x, (x \leq 42 \land 42 \leq x) \to \text{is_fortytwo } x.
```

```
Proof.
  info\_auto.
Qed.
Hint Constructors ceval.
Definition st12 := update (update empty_state X 1) Y 2.
Definition st21 := update (update empty_state X 2) Y 1.
Example auto_example_8 : \exists s',
  (IFB (BLe (Ald X) (Ald Y))
    THEN (Z := AMinus (Ald Y) (Ald X))
    ELSE (Y ::= APlus (Ald X) (Ald Z))
  FI) / st21 || s'.
Proof.
  eexists. info_-auto.
Qed.
Example auto_example_8': \exists s',
  (IFB (BLe (Ald X) (Ald Y))
    THEN (Z := AMinus (Ald Y) (Ald X))
    ELSE (Y ::= APlus (Ald X) (Ald Z))
  FI) / st12 || s'.
Proof.
  eexists. info_-auto.
Qed.
```

Now let's take a pass over ceval\_deterministic using auto to simplify the proof script. We see that all simple sequences of hypothesis applications and all uses of reflexivity can be replaces by auto, which we add to the default tactic to be applied to each case.

```
Theorem ceval_deterministic': \forall c \ st \ st1 \ st2,
      c / st \mid \mid st1 \rightarrow
      c / st \mid \mid st2 \rightarrow
      st1 = st2.
Proof.
  intros c st st1 st2 E1 E2;
  generalize dependent st2;
  ceval_cases (induction E1) Case;
              intros st2 E2; inv E2; auto.
  Case "E_Seq".
     assert (st' = st'\theta) as EQ1.
        SCase "Proof of assertion". auto.
     subst st'0.
     auto.
  Case "E_IfTrue".
     SCase "b evaluates to false (contradiction)".
```

```
rewrite H in H5. inversion H5.

Case "E_IfFalse".

SCase "b evaluates to true (contradiction)".

rewrite H in H5. inversion H5.

Case "E_WhileEnd".

SCase "b evaluates to true (contradiction)".

rewrite H in H2. inversion H2.

Case "E_WhileLoop".

SCase "b evaluates to false (contradiction)".

rewrite H in H4. inversion H4.

SCase "b evaluates to true".

assert (st' = st'0) as EQ1.

SSCase "Proof of assertion". auto.

subst st'0.

auto. Qed.
```

# 16.3 Searching Hypotheses

The proof has become simpler, but there is still an annoying amount of repetition. Let's start by tackling the contradiction cases. Each of them occurs in a situation where we have both

```
H1: beval st b = false and H2: beval st b = true
```

as hypotheses. The contradiction is evident, but demonstrating it is a little complicated: we have to locate the two hypotheses H1 and H2 and do a rewrite following by an inversion. We'd like to automate this process.

Note: In fact, Coq has a built-in tactic **congruence** that will do the job. But we'll ignore the existence of this tactic for now, in order to demonstrate how to build forward search tactics by hand.

As a first step, we can abstract out the piece of script in question by writing a small amount of paramerized Ltac.

```
Ltac rwinv H1 H2 := rewrite H1 in H2; inv H2.

Theorem ceval_deterministic": \forall c st st1 st2,

c / st | | st1 \rightarrow

c / st | | st2 \rightarrow

st1 = st2.

Proof.

intros c st st1 st2 st2 st2 st2 st2 st2 st2 st2 st3 st3 st3 st3 st3 st3 st3 st3 st3 st4 st3 st4 st5 st5
```

```
intros st2 E2; inv E2; auto.
Case "E_Seq".
  assert (st' = st'0) as EQ1.
    SCase "Proof of assertion". auto.
  subst st'0.
  auto.
Case "E_IfTrue".
  SCase "b evaluates to false (contradiction)".
    rwinv H H5.
Case "E_IfFalse".
  SCase "b evaluates to true (contradiction)".
    rwinv H H5.
Case "E_WhileEnd".
  SCase "b evaluates to true (contradiction)".
    rwinv H H2.
Case "E_WhileLoop".
  SCase "b evaluates to false (contradiction)".
    rwinv H H4.
  SCase "b evaluates to true".
    assert (st' = st'\theta) as EQ1.
      SSCase "Proof of assertion". auto.
    subst st'0.
    auto. Qed.
```

But this is not much better. We really want Coq to discover the relevant hypotheses for us. We can do this by using the match goal with ... end facility of Ltac.

```
Ltac find\_rwinv := match goal with H1: ?E = \mathsf{true}, \ H2: ?E = \mathsf{false} \vdash \_ \Rightarrow rwinv \ H1 \ H2 end.
```

In words, this match goal looks for two (distinct) hypotheses that have the form of equalities with the same arbitrary expression E on the left and conflicting boolean values on the right; if such hypotheses are found, it binds H1 and H2 to their names, and applies the tactic after the  $\Rightarrow$ .

Adding this tactic to our default string handles all the contradiction cases.

```
Theorem ceval_deterministic''': \forall c \ st \ st1 \ st2, c \ / \ st \ | \ | \ st1 \rightarrow c \ / \ st \ | \ | \ st2 \rightarrow st1 = st2.

Proof.

intros c \ st \ st1 \ st2 \ E1 \ E2;
generalize dependent st2;
```

```
ceval\_cases \ (\text{induction} \ E1) \ Case;  \text{intros} \ st2 \ E2; \ inv \ E2; \ try \ find\_rwinv; \ \text{auto}. Case \ "E\_Seq".  \text{assert} \ (st' = st'0) \ \text{as} \ EQ1.  SCase \ "Proof \ of \ assertion". \ \text{auto}.  subst \ st'0.  \text{auto}.  Case \ "E\_WhileLoop".  SCase \ "b \ evaluates \ to \ true".  \text{assert} \ (st' = st'0) \ \text{as} \ EQ1.  SCase \ "Proof \ of \ assertion". \ \text{auto}.  subst \ st'0.  \text{auto}. \ \mathbb{Q}ed.
```

Finally, let's see about the remaining cases. Each of them involves applying a conditional hypothesis to extract an equality. Currently we have phrased these as assertions, so that we have to predict what the resulting equality will be (although we can then use **auto** to prove it.) An alternative is to pick the relevant hypotheses to use, and then rewrite with them, as follows:

```
Theorem ceval_deterministic''': \forall c \ st \ st1 \ st2,
      c / st \mid \mid st1 \rightarrow
      c / st \mid \mid st2 \rightarrow
      st1 = st2.
Proof.
  intros c st st1 st2 E1 E2;
  generalize dependent st2;
  ceval_cases (induction E1) Case;
             intros st2 E2; inv E2; try find_rwinv; auto.
  Case "E_Seq".
    rewrite (IHE1_1 st'0 H1) in *. auto.
  Case "E_WhileLoop".
     SCase "b evaluates to true".
       rewrite (IHE1_1 st'0 H3) in *. auto. Qed.
   Now we can automate the task of finding the relevant hypotheses to rewrite with.
Ltac find_-eqn :=
  match goal with
     H1: \forall x, ?P x \rightarrow ?L = ?R, H2: ?P ?X \vdash \_ \Rightarrow
           rewrite (H1 \ X \ H2) in *
  end.
```

But there are several pairs of hypotheses that have the correct general form, and it seems tricky to pick out the correct ones. The important thing to realize is that we can *try them all!* Here's how this works:

- rewrite will fail given a trivial equation of the form X = X.
- each execution of match goal will keep trying to find a valid pair of hypotheses until the tactic on the RHS of the match succeeds; if there are no such pairs, it fails.
- we can wrap the whole thing in a **repeat** which will keep doing useful rewrites until only trivial ones are left.

```
Theorem ceval_deterministic'''': \forall \ c \ st \ st1 \ st2,
c \ / \ st \ | \ | \ st1 \rightarrow
c \ / \ st \ | \ | \ st2 \rightarrow
st1 = st2.
Proof.
intros c \ st \ st1 \ st2 \ E1 \ E2;
generalize dependent st2;
ceval\_cases \ (\text{induction} \ E1) \ Case;
intros \ st2 \ E2; \ inv \ E2; \ try \ find\_rwinv; \ repeat \ find\_eqn; \ auto.
Qed.
```

The big pay-off in this approach is that our proof script should be robust in the face of modest changes to our language. For example, we can add a REPEAT command to the language. (This was an exercise in Hoare.v.)

Module REPEAT.

REPEAT behaves like WHILE, except that the loop guard is checked after each execution of the body, with the loop repeating as long as the guard stays false. Because of this, the body will always execute at least once.

```
Tactic Notation "com_cases" tactic(first) \ ident(c) := first;

# Library Smallstep

# 17.1 Smallstep: Small-step Operational Semantics

Require Export Imp.

The evaluators we have seen so far (e.g., the ones for **aexp**s, **bexp**s, and commands) have been formulated in a "big-step" style – they specify how a given expression can be evaluated to its final value (or a command plus a store to a final store) "all in one big step."

This style is simple and natural for many purposes – indeed, Gilles Kahn, who popularized its use, called it *natural semantics*. But there are some things it does not do well. In particular, it does not give us a natural way of talking about *concurrent* programming languages, where the "semantics" of a program – i.e., the essence of how it behaves – is not just which input states get mapped to which output states, but also includes the intermediate states that it passes through along the way, since these states can also be observed by concurrently executing code.

Another shortcoming of the big-step style is more technical, but critical in some situations. To see the issue, suppose we wanted to define a variant of Imp where variables could hold either numbers or lists of numbers (see the HoareList chapter for details). In the syntax of this extended language, it will be possible to write strange expressions like 2 + nil, and our semantics for arithmetic expressions will then need to say something about how such expressions behave. One possibility (explored in the HoareList chapter) is to maintain the convention that every arithmetic expressions evaluates to some number by choosing some way of viewing a list as a number - e.g., by specifying that a list should be interpreted as 0 when it occurs in a context expecting a number. But this is really a bit of a hack.

A much more natural approach is simply to say that the behavior of an expression like 2+nil is *undefined* – it doesn't evaluate to any result at all. And we can easily do this: we just have to formulate aeval and beval as Inductive propositions rather than Fixpoints, so that we can make them partial functions instead of total ones.

However, now we encounter a serious deficiency. In this language, a command might fail to map a given starting state to any ending state for two quite different reasons: either because the execution gets into an infinite loop or because, at some point, the program tries

to do an operation that makes no sense, such as adding a number to a list, and none of the evaluation rules can be applied.

These two outcomes – nontermination vs. getting stuck in an erroneous configuration – are quite different. In particular, we want to allow the first (permitting the possibility of infinite loops is the price we pay for the convenience of programming with general looping constructs like *while*) but prevent the second (which is just wrong), for example by adding some form of *typechecking* to the language. Indeed, this will be a major topic for the rest of the course. As a first step, we need a different way of presenting the semantics that allows us to distinguish nontermination from erroneous "stuck states."

So, for lots of reasons, we'd like to have a finer-grained way of defining and reasoning about program behaviors. This is the topic of the present chapter. We replace the "big-step" eval relation with a "small-step" relation that specifies, for a given program, how the "atomic steps" of computation are performed.

### 17.2 Relations

A relation on a set X is a family of propositions parameterized by two elements of X – i.e., a proposition about pairs of elements of X.

```
Definition relation (X: \mathsf{Type}) := X \rightarrow X \rightarrow \mathsf{Prop}.
```

Our main examples of such relations in this chapter will be the single-step and multi-step reduction relations on terms, ==> and ==>\*, but there are many other examples – some that come to mind are the "equals," "less than," "less than or equal to," and "is the square of" relations on numbers, and the "prefix of" relation on lists and strings.

## 17.3 A Toy Language

To save space in the discussion, let's go back to an incredibly simple language containing just constants and addition. (We use single letters - C and P - for the constructor names, for brevity.) At the end of the chapter, we'll see how to apply the same techniques to the full Imp language.

```
\label{eq:condition} \begin{array}{l} \text{Inductive } \mathbf{tm} : \texttt{Type} := \\ \mid \mathsf{C} : \mathbf{nat} \to \mathbf{tm} \\ \mid \mathsf{P} : \mathbf{tm} \to \mathbf{tm} \to \mathbf{tm}. \\ \\ \text{Tactic Notation "tm\_cases" } \textit{tactic}(\texttt{first}) \; \textit{ident}(c) := \\ \text{first}; \\ \mid \textit{Case\_aux} \; c \; \text{"C"} \mid \textit{Case\_aux} \; c \; \text{"P"} \mid . \end{array}
```

Here is a standard evaluator for this language, written in the same (big-step) style as we've been using up to this point.

```
Fixpoint evalF (t : tm) : nat := match t with
```

```
\mid C n \Rightarrow n
\mid P a1 a2 \Rightarrow evalF a1 + evalF a2 end.
```

Now, here is the same evaluator, written in exactly the same style, but formulated as an inductively defined relation. Again, we use the notation  $t \parallel \mathbf{n}$  for "t evaluates to  $\mathbf{n}$ ."

```
(E_Const) C n || n
   t1 || n1 t2 || n2
(E_Plus) P t1 t2 || C (n1 + n2)
Reserved Notation "t'||'n "(at level 50, left associativity).
Inductive eval: tm \rightarrow nat \rightarrow Prop :=
  \mid \mathsf{E}_{\mathsf{-}}\mathsf{Const} : \forall n,
        C n \mid \mid n
  \mid \mathsf{E}_{-}\mathsf{Plus} : \forall t1 \ t2 \ n1 \ n2,
        t1 \mid \mid n1 \rightarrow
        t2 \mid \mid n2 \rightarrow
       P t1 \ t2 \ | \ (n1 + n2)
  where " t '||' n " := (eval t n).
Tactic Notation "eval_cases" tactic(first) ident(c) :=
  first:
  [ Case\_aux \ c "E_Const" | Case\_aux \ c "E_Plus" ].
Module SIMPLEARITH1.
    Now, here is a small-step version.
(ST_PlusConstConst) P (C n1) (C n2) ==> C (n1 + n2)
    t1 ==> t1'
(ST_Plus1) P t1 t2 ==> P t1' t2
   t2 ==> t2'
(ST_Plus2) P (C n1) t2 ==> P (C n1) t2'
Reserved Notation "t'==>'t' (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_PlusConstConst : \forall n1 n2,
        P(C n1)(C n2) \Longrightarrow C(n1 + n2)
  | ST_Plus1 : ∀ t1 t1 ′ t2,
       t1 ==> t1' \rightarrow
       P t1 t2 ==> P t1' t2
```

```
| \ \mathsf{ST\_Plus2} : \forall \ n1 \ t2 \ t2', t2 ==> t2' \rightarrow \\ \mathsf{P} \ (\mathsf{C} \ n1) \ t2 ==> \mathsf{P} \ (\mathsf{C} \ n1) \ t2' where " t '==>' t' " := (step t \ t'). Tactic Notation "step_cases" tactic(\mathsf{first}) \ ident(c) := \mathsf{first}; [ Case\_aux \ c "ST_PlusConstConst" | Case\_aux \ c "ST_Plus1" | Case\_aux \ c "ST_Plus2" ]. Things to notice:
```

- We are defining just a single reduction step, in which one P node is replaced by its value.
- Each step finds the *leftmost* P node that is ready to go (both of its operands are constants) and rewrites it in place. The first rule tells how to rewrite this P node itself; the other two rules tell how to find it.
- A term that is just a constant cannot take a step.

Let's pause and check a couple of examples of reasoning with the **step** relation... If t1 can take a step to t1, then P t1 t2 steps to P t1, t2:

```
Example test_step_1:
```

```
P
(P (C 0) (C 3))
(P (C 2) (C 4))
==>
P
(C (0 + 3))
(P (C 2) (C 4)).
```

Proof.

apply ST\_Plus1. apply ST\_PlusConstConst. Qed.

Exercise: 1 star (test\_step\_2) Right-hand sides of sums can take a step only when the left-hand side is finished: if t2 can take a step to t2', then P (C n) t2 steps to P (C n) t2':

Example test\_step\_2 :

```
P
(C 0)
(P
(C 2)
(P (C 0) (C 3)))
```

```
P
(C 0)
(P
(C 2)
(C (0 + 3))).

Proof.

Admitted.
```

One simple property of the ==> relation is that, like the evaluation relation for our language of Imp programs, it is deterministic.

Theorem: For each t, there is at most one t' such that t steps to t' (t ==> t' is provable). Formally, this is the same as saying that ==> is deterministic.

*Proof sketch*: We show that if x steps to both y1 and y2 then y1 and y2 are equal, by induction on a derivation of **step** x y1. There are several cases to consider, depending on the last rule used in this derivation and in the given derivation of **step** x y2.

- If both are ST\_PlusConstConst, the result is immediate.
- The cases when both derivations end with ST\_Plus1 or ST\_Plus2 follow by the induction hypothesis.
- It cannot happen that one is ST\_PlusConstConst and the other is ST\_Plus1 or ST\_Plus2, since this would imply that x has the form P t1 t2 where both t1 and t2 are constants (by ST\_PlusConstConst) and one of t1 or t2 has the form P ....
- Similarly, it cannot happen that one is  $ST_Plus1$  and the other is  $ST_Plus2$ , since this would imply that x has the form P t1 t2 where t1 has both the form P t1 t2 and the form C n.  $\square$

```
Definition deterministic \{X\colon \mathsf{Type}\}\ (R\colon \mathsf{relation}\ X) := \ \forall\ x\ y1\ y2: X,\ R\ x\ y1 \to R\ x\ y2 \to y1 = y2.
Theorem step_deterministic:
    deterministic step.

reflexivity. assumption. Qed.
```

End SIMPLEARITH1.

#### 17.3.1 Values

Let's take a moment to slightly generalize the way we state the definition of single-step reduction.

It is useful to think of the ==> relation as defining an abstract machine:

- At any moment, the *state* of the machine is a term.
- A step of the machine is an atomic unit of computation here, a single "add" operation.
- The *halting states* of the machine are ones where there is no more computation to be done.

We can then execute a term t as follows:

- Take t as the starting state of the machine.
- Repeatedly use the ==> relation to find a sequence of machine states, starting with t, where each state steps to the next.
- When no more reduction is possible, "read out" the final state of the machine as the result of execution.

Intuitively, it is clear that the final states of the machine are always terms of the form C n for some n. We call such terms *values*.

```
Inductive value : tm \rightarrow Prop := v\_const : \forall n, value (C n).
```

Having introduced the idea of values, we can use it in the definition of the ==> relation to write ST\_Plus2 rule in a slightly more elegant way:

```
(ST_PlusConstConst) P (C n1) (C n2) ==> C (n1 + n2) t1 ==> t1'
```

```
(ST_Plus1) P t1 t2 ==> P t1' t2 value v1 t2 ==> t2'
```

(ST\_Plus2) P v1 t2 ==> P v1 t2' Again, the variable names here carry important information: by convention, v1 ranges only over values, while t1 and t2 range over arbitrary terms. (Given this convention, the explicit **value** hypothesis is arguably redundant. We'll keep it for now, to maintain a close correspondence between the informal and Coq versions of the rules, but later on we'll drop it in informal rules, for the sake of brevity.)

```
Reserved Notation " t = > t' " (at level 40).
```

```
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_PlusConstConst : \forall n1 n2,
             P (C n1) (C n2)
       => C (n1 + n2)
  | ST_Plus1 : \forall t1 \ t1' \ t2,
          t1 ==> t1' \rightarrow
          P t1 t2 ==> P t1' t2
  | ST_Plus2 : \forall v1 \ t2 \ t2',
          value v1 \rightarrow
          t2 ==> t2' \rightarrow
          P v1 t2 ==> P v1 t2'
  where " t '==>' t' " := (step t \ t').
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first;
  [ Case_aux c "ST_PlusConstConst"
  | Case_aux c "ST_Plus1" | Case_aux c "ST_Plus2" |.
```

Exercise: 3 stars (redo\_determinism) As a sanity check on this change, let's re-verify determinism

Proof sketch: We must show that if x steps to both y1 and y2 then y1 and y2 are equal. Consider the final rules used in the derivations of **step** x y1 and **step** x y2.

- If both are ST\_PlusConstConst, the result is immediate.
- It cannot happen that one is ST\_PlusConstConst and the other is ST\_Plus1 or ST\_Plus2, since this would imply that x has the form P t1 t2 where both t1 and t2 are constants (by ST\_PlusConstConst) AND one of t1 or t2 has the form P ....
- Similarly, it cannot happen that one is ST\_Plus1 and the other is ST\_Plus2, since this would imply that x has the form P t1 t2 where t1 both has the form P t1 t2 and is a value (hence has the form C n).

 The cases when both derivations end with ST\_Plus1 or ST\_Plus2 follow by the induction hypothesis. □

Most of this proof is the same as the one above. But to get maximum benefit from the exercise you should try to write it from scratch and just use the earlier one if you get stuck.

Theorem step\_deterministic : deterministic step.

Proof.

Admitted.

### 17.3.2 Strong Progress and Normal Forms

The definition of single-step reduction for our toy language is fairly simple, but for a larger language it would be pretty easy to forget one of the rules and create a situation where some term cannot take a step even though it has not been completely reduced to a value. The following theorem shows that we did not, in fact, make such a mistake here.

Theorem (Strong Progress): If t is a term, then either t is a value, or there exists a term t' such that t ==> t'.

*Proof*: By induction on t.

- Suppose t = C n. Then t is a value.
- Suppose t = P t1 t2, where (by the IH) t1 is either a value or can step to some t1, and where t2 is either a value or can step to some t2. We must show P t1 t2 is either a value or steps to some t.
  - If t1 and t2 are both values, then t can take a step, by  $ST_PlusConstConst$ .
  - If t1 is a value and t2 can take a step, then so can t, by  $ST_Plus2$ .
  - If t1 can take a step, then so can t, by  $ST_Plus1$ .  $\square$

```
Theorem strong_progress : \forall t, value t \lor (\exists t', t ==> t').

Proof.

tm\_cases (induction t) Case.

Case "C". left. apply v_const.

Case "P". right. inversion IHt1.

SCase "l". inversion IHt2.

SSCase "l". inversion H. inversion H0.

\exists (C (n + n0)).

apply ST\_PlusConstConst.

SSCase "r". inversion H0 as [t', H1].
```

```
\exists (P t1\ t'). apply ST_Plus2. apply H. apply H1. SCase "r". inversion H as [t'\ H0]. \exists (P t'\ t2). apply ST_Plus1. apply H0. Qed.
```

This important property is called *strong progress*, because every term either is a value or can "make progress" by stepping to some other term. (The qualifier "strong" distinguishes it from a more refined version that we'll see in later chapters, called simply "progress.")

The idea of "making progress" can be extended to tell us something interesting about **values**: in this language **values** are exactly the terms that *cannot* make progress in this sense.

To state this observation formally, let's begin by giving a name to terms that cannot make progress. We'll call them *normal forms*.

```
Definition normal_form \{X: \mathtt{Type}\}\ (R: \mathtt{relation}\ X)\ (t:X): \mathtt{Prop} := \neg \exists\ t',\ R\ t\ t'.
```

This definition actually specifies what it is to be a normal form for an *arbitrary* relation **R** over an arbitrary set X, not just for the particular single-step reduction relation over terms that we are interested in at the moment. We'll re-use the same terminology for talking about other relations later in the course.

We can use this terminology to generalize the observation we made in the strong progress theorem: in this language, normal forms and values are actually the same thing.

```
Lemma value_is_nf : \forall v,
  value v \rightarrow \text{normal\_form step } v.
Proof.
  unfold normal_form. intros v H. inversion H.
  intros contra. inversion contra. inversion H1.
Qed.
Lemma nf_{is}-value : \forall t,
  normal_form step t \rightarrow \text{value } t.
           unfold normal_form. intros t H.
  assert (G : \mathsf{value}\ t \lor \exists\ t',\ t ==> t').
     SCase "Proof of assertion". apply strong_progress.
  inversion G.
     SCase "l". apply H0.
     SCase "r". apply ex_falso_quodlibet. apply H. assumption. Qed.
Corollary nf_{same_as_value} : \forall t,
  normal_form step t \leftrightarrow \text{value } t.
Proof.
  split. apply nf_is_value. apply value_is_nf. Qed.
    Why is this interesting?
```

Because **value** is a syntactic concept – it is defined by looking at the form of a term – while **normal\_form** is a semantic one – it is defined by looking at how the term steps. It is not obvious that these concepts should coincide!

Indeed, we could easily have written the definitions so that they would not coincide...

We might, for example, mistakenly define **value** so that it includes some terms that are not finished reducing.

```
Module TEMP1.
Inductive value : tm \rightarrow Prop :=
| v_{\text{-}} const : \forall n, value (C n)
| v_{\text{funny}} : \forall t1 \ n2,
                  value (P t1 (C n2)).
Reserved Notation "t'==>'t' (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_PlusConstConst : \forall n1 n2,
       P(C n1)(C n2) \Longrightarrow C(n1 + n2)
  | ST_Plus1 : \forall t1 \ t1' \ t2,
       t1 ==> t1' \rightarrow
       P t1 t2 ==> P t1' t2
  | ST_Plus2 : \forall v1 \ t2 \ t2',
       value v1 \rightarrow
       t2 ==> t2' \rightarrow
       P v1 t2 ==> P v1 t2'
  where " t '==>' t' " := (step t \ t').
Exercise: 3 stars, advanced (value_not_same_as_normal_form) Lemma value_not_same_as_normal
  \exists v, value v \land \neg normal_form step v.
Proof.
    Admitted.
   End TEMP1.
    Alternatively, we might mistakenly define step so that it permits something designated
as a value to reduce further.
Module TEMP2.
Inductive value : tm \rightarrow Prop :=
| v_{\text{-}} const : \forall n, value (C n).
Reserved Notation "t'==>'t' (at level 40).
```

Inductive **step** :  $tm \rightarrow tm \rightarrow Prop :=$ 

```
| ST_PlusConstConst : \forall n1 n2,
       P(C n1)(C n2) \Longrightarrow C(n1 + n2)
  | ST_Plus1 : \forall t1 \ t1' \ t2,
       t1 ==> t1' \rightarrow
       P t1 t2 ==> P t1' t2
  | ST_Plus2 : ∀ v1 t2 t2',
       value v1 \rightarrow
       t2 ==> t2' \rightarrow
       P v1 t2 ==> P v1 t2'
  where " t '==>' t' " := (step t \ t').
Exercise: 2 stars, advanced (value_not_same_as_normal_form)  Lemma value_not_same_as_normal
  \exists v, value v \land \neg \text{ normal\_form step } v.
Proof.
    Admitted.
   End TEMP2.
```

Finally, we might define **value** and **step** so that there is some term that is not a value but that cannot take a step in the **step** relation. Such terms are said to be *stuck*. In this case this is caused by a mistake in the semantics, but we will also see situations where, even in a correct language definition, it makes sense to allow some terms to be stuck.

Module TEMP3.

 $\mid \mathsf{ST}_{\mathsf{-}}\mathsf{Funny} : \forall n,$ 

 $C n \Longrightarrow P (C n) (C 0)$ 

```
Inductive value: tm \rightarrow Prop := | v\_const : \forall n, value (C n).
Reserved Notation " t '==>' t' " (at level 40).

Inductive step : tm \rightarrow tm \rightarrow Prop := | ST\_PlusConstConst : \forall n1 n2, P (C n1) (C n2) ==> C (n1 + n2) | ST\_Plus1 : \forall t1 t1' t2, t1 ==> t1' \rightarrow P t1 t2 ==> P t1' t2

where " t '==>' t' " := (step t t').

(Note that ST\_Plus2 is missing.)
```

```
Exercise: 3 stars, advanced (value_not_same_as_normal_form') Lemma value_not_same_as_normal:
\exists t, \neg \text{ value } t \land \text{ normal_form step } t.
Proof.
Admitted.
```

#### **Additional Exercises**

Module TEMP4.

End TEMP3.

Here is another very simple language whose terms, instead of being just plus and numbers, are just the booleans true and false and a conditional expression...

```
Inductive tm : Type :=
   ttrue : tm
    tfalse : tm
   \mid \mathsf{tif} : \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}.
Inductive value : tm \rightarrow Prop :=
  | v_true : value ttrue
  | v_false : value tfalse.
Reserved Notation "t'==>'t' (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_IfTrue : \forall t1 t2,
        tif ttrue t1 t2 ==> t1
  | ST_IfFalse : \forall t1 t2,
        tif tfalse t1 t2 ==> t2
  \mid ST_If : \forall t1 t1' t2 t3,
        t1 ==> t1' \rightarrow
        tif t1 t2 t3 ==> tif t1' t2 t3
  where " t '==>' t' " := (step t \ t').
```

Exercise: 1 star (smallstep\_bools) Which of the following propositions are provable? (This is just a thought exercise, but for an extra challenge feel free to prove your answers in Coq.)

```
Definition bool_step_prop1 :=
   tfalse ==> tfalse.
Definition bool_step_prop2 :=
    tif
        ttrue
```

```
(tif ttrue ttrue ttrue)
    (tif tfalse tfalse tfalse)
==>
    ttrue.

Definition bool_step_prop3 :=
    tif
        (tif ttrue ttrue ttrue)
        (tif ttrue ttrue ttrue)
        tfalse
==>
    tif
        ttrue
        (tif ttrue ttrue ttrue)
```

Exercise: 3 stars, optional (progress\_bool) Just as we proved a progress theorem for plus expressions, we can do so for boolean expressions, as well.

```
Theorem strong_progress : \forall t, value t \lor (\exists t', t ==> t'). Proof.

Admitted.
```

Exercise: 2 stars, optional (step\_deterministic) Theorem step\_deterministic : deterministic step.

 ${\bf Proof.} \\ Admitted.$ 

Module TEMP5.

Exercise: 2 stars (smallstep\_bool\_shortcut) Suppose we want to add a "short circuit" to the step relation for boolean expressions, so that it can recognize when the then and else branches of a conditional are the same value (either ttrue or tfalse) and reduce the whole conditional to this value in a single step, even if the guard has not yet been reduced to a value. For example, we would like this proposition to be provable: tif (tif ttrue ttrue ttrue) tfalse tfalse ==> tfalse.

Write an extra clause for the step relation that achieves this effect and prove bool\_step\_prop4.

Reserved Notation " t :==>' t' " (at level 40).

```
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_lfTrue : \forall t1 t2,
        tif ttrue t1 t2 ==> t1
  | ST_IfFalse : \forall t1 t2,
        tif tfalse t1 t2 ==> t2
  \mid ST_If : \forall t1 t1' t2 t3,
        t1 \Longrightarrow t1' \rightarrow
        tif t1 t2 t3 ==> tif t1' t2 t3
  where " t '==>' t' " := (step t \ t').
   Definition bool_step_prop4 :=
            tif
                (tif ttrue ttrue ttrue)
                tfalse
                tfalse
            tfalse.
Example bool_step_prop4_holds :
  bool_step_prop4.
Proof.
    Admitted.
```

Exercise: 3 stars, optional (properties\_of\_altered\_step) It can be shown that the determinism and strong progress theorems for the step relation in the lecture notes also hold for the definition of step given above. After we add the clause  $ST\_ShortCircuit...$ 

• Is the **step** relation still deterministic? Write yes or no and briefly (1 sentence) explain your answer.

Optional: prove your answer correct in Coq.

• Does a strong progress theorem hold? Write yes or no and briefly (1 sentence) explain your answer.

Optional: prove your answer correct in Coq.

• In general, is there any way we could cause strong progress to fail if we took away one or more constructors from the original step relation? Write yes or no and briefly (1 sentence) explain your answer.

End TEMP5.
End TEMP4.

## 17.4 Multi-Step Reduction

Until now, we've been working with the single-step reduction relation ==>, which formalizes the individual steps of an abstract machine for executing programs.

We can also use this machine to reduce programs to completion – to find out what final result they yield. This can be formalized as follows:

- First, we define a multi-step reduction relation  $==>^*$ , which relates terms t and t' if t can reach t' by any number of single reduction steps (including zero steps!).
- $\bullet$  Then we define a "result" of a term t as a normal form that t can reach by multi-step reduction.

Since we'll want to reuse the idea of multi-step reduction many times in this and future chapters, let's take a little extra trouble here and define it generically.

Given a relation R, we define a relation multi R, called the *multi-step closure of* R as follows:

```
Inductive multi \{X: \texttt{Type}\}\ (R: \texttt{relation}\ X) : \texttt{relation}\ X := | \texttt{multi\_refl}: \ \forall \ (x:X), \ \texttt{multi}\ R\ x\ x | | \texttt{multi\_step}: \ \forall \ (x\ y\ z:X), \\ R\ x\ y \rightarrow \\ \texttt{multi}\ R\ y\ z \rightarrow \\ \texttt{multi}\ R\ x\ z.
```

The effect of this definition is that **multi** R relates two elements x and y if either

- $\bullet$  x = y, or else
- there is some sequence z1, z2, ..., zn such that R x z1 R z1 z2 ... R zn y.

Thus, if  $\mathbf{R}$  describes a single-step of computation,  $z1, \dots zn$  is the sequence of intermediate steps of computation between  $\mathbf{x}$  and  $\mathbf{y}$ .

```
Tactic Notation "multi_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c "multi_refl" | Case\_aux \ c "multi_step" ].
```

We write  $==>^*$  for the **multi step** relation – i.e., the relation that relates two terms t and t' if we can get from t to t' using the **step** relation zero or more times.

Definition multistep := multi step.

```
Notation " t'==>^*' t'" := (multistep t') (at level 40).
```

The relation **multi** R has several crucial properties.

First, it is obviously *reflexive* (that is,  $\forall$  x, **multi** R x x). In the case of the ==>\* (i.e. **multi step**) relation, the intuition is that a term can execute to itself by taking zero steps of execution.

Second, it contains  $\mathsf{R}$  – that is, single-step executions are a particular case of multi-step executions. (It is this fact that justifies the word "closure" in the term "multi-step closure of  $\mathsf{R}$ .")

```
Theorem multi_R: \forall (X:Type) (R:relation X) (x y : X),
        R \ x \ y \rightarrow (\mathbf{multi} \ R) \ x \ y.
Proof.
  intros X R x y H.
  apply multi_step with y. apply H. apply multi_refl. Qed.
   Third, multi R is transitive.
Theorem multi_trans:
  \forall (X:\mathsf{Type}) (R: \mathsf{relation}\ X) (x\ y\ z:X),
       multi R x y \rightarrow
       multi R \ y \ z \rightarrow
       multi R x z.
Proof.
  intros X R x y z G H.
  multi_cases (induction G) Case.
     Case "multi_refl". assumption.
     Case "multi_step".
       apply multi_step with y. assumption.
       apply IHG. assumption. Qed.
   That is, if t1 = > t2 and t2 = > t3, then t1 = > t3.
```

### 17.4.1 Examples

```
Lemma test_multistep_1:

P

(P (C 0) (C 3))
(P (C 2) (C 4))
==>*

C ((0 + 3) + (2 + 4)).

Proof.

apply multi_step with

(P (C (0 + 3)))
(P (C 2) (C 4)).
```

```
apply ST_Plus1. apply ST_PlusConstConst.
  apply multi_step with
             (P
                 (C(0+3))
                 (C(2+4)).
  apply ST_Plus2. apply v_const.
  apply ST_PlusConstConst.
  apply multi_R.
  apply ST_PlusConstConst. Qed.
   Here's an alternate proof that uses eapply to avoid explicitly constructing all the inter-
mediate terms.
Lemma test_multistep_1':
      Ρ
        (P(C 0)(C 3))
        (P(C2)(C4))
  ==>*
      C((0+3)+(2+4)).
Proof.
  eapply multi_step. apply ST_Plus1. apply ST_PlusConstConst.
  eapply multi_step. apply ST_Plus2. apply v_const.
  apply ST_PlusConstConst.
  eapply multi_step. apply ST_PlusConstConst.
  apply multi_refl. Qed.
Exercise: 1 star, optional (test_multistep_2) Lemma test_multistep_2:
  C 3 ==>* C 3.
Proof.
   Admitted.
   Exercise: 1 star, optional (test_multistep_3) Lemma test_multistep_3:
      P (C 0) (C 3)
   ==>*
      P (C 0) (C 3).
Proof.
   Admitted.
   Exercise: 2 stars (test_multistep_4) Lemma test_multistep_4:
      Ρ
        (C 0)
        (P
```

```
(C 2)
(P (C 0) (C 3)))
==>*
P
(C 0)
(C (2 + (0 + 3))).
Proof.
Admitted.
```

### 17.4.2 Normal Forms Again

If t reduces to t' in zero or more steps and t' is a normal form, we say that "t' is a normal form of t."

```
{\tt Definition\ step\_normal\_form\ :=\ normal\_form\ step}.
```

```
Definition normal_form_of (t \ t' : \mathbf{tm}) := (t ==>* \ t' \land \mathsf{step\_normal\_form} \ t').
```

We have already seen that, for our language, single-step reduction is deterministic – i.e., a given term can take a single step in at most one way. It follows from this that, if t can reach a normal form, then this normal form is unique. In other words, we can actually pronounce normal\_form t t as "t" is the normal form of t."

Exercise: 3 stars, optional (normal\_forms\_unique) Theorem normal\_forms\_unique: deterministic normal\_form\_of.

Proof.

```
unfold deterministic. unfold normal_form_of. intros x y1 y2 P1 P2. inversion P1 as [P11 P12]; clear P1. inversion P2 as [P21 P22]; clear P2. generalize dependent y2. Admitted.
```

Indeed, something stronger is true for this language (though not for all languages): the reduction of any term t will eventually reach a normal form – i.e., normal\_form\_of is a total function. Formally, we say the **step** relation is normalizing.

```
Definition normalizing \{X: \texttt{Type}\}\ (R: \texttt{relation}\ X) := \forall\ t,\ \exists\ t',\ (\texttt{multi}\ R)\ t\ t' \land \texttt{normal\_form}\ R\ t'.
```

To prove that **step** is normalizing, we need a couple of lemmas.

First, we observe that, if t reduces to t' in many steps, then the same sequence of reduction steps within t is also possible when t appears as the left-hand child of a P node, and similarly when t appears as the right-hand child of a P node whose left-hand child is a value.

```
Lemma multistep_congr_1 : \forall t1 \ t1' \ t2,
     t1 ==>* t1' \rightarrow
     P t1 t2 ==>* P t1' t2.
Proof.
  intros t1 t1' t2 H. multi_cases (induction H) Case.
     Case "multi_refl". apply multi_refl.
     Case "multi_step". apply multi_step with (P y t2).
         apply ST_Plus1. apply H.
         apply IHmulti. Qed.
Exercise: 2 stars (multistep_congr_2) Lemma multistep_congr_2: \forall t1 \ t2 \ t2',
     value t1 \rightarrow
     t2 ==>* t2' \rightarrow
     P t1 t2 ==>* P t1 t2'.
Proof.
   Admitted.
   Theorem: The step function is normalizing – i.e., for every t there exists some t' such
that t steps to t' and t' is a normal form.
   Proof sketch: By induction on terms. There are two cases to consider:
   • t = \mathsf{C} \mathsf{n} for some \mathsf{n}. Here t doesn't take a step, and we have t' = t. We can derive the
     left-hand side by reflexivity and the right-hand side by observing (a) that values are
     normal forms (by nf_same_as_value) and (b) that t is a value (by v_const).
   • t = P t1 t2 for some t1 and t2. By the IH, t1 and t2 have normal forms t1 and t2.
     Recall that normal forms are values (by nf_same_as_value); we know that t1' = C n1
     and t2' = C n2, for some n1 and n2. We can combine the ==>* derivations for t1
     and t2 to prove that P t1 t2 reduces in many steps to C (n1 + n2).
     It is clear that our choice of t' = C (n1 + n2) is a value, which is in turn a normal
     form. \square
Theorem step_normalizing:
  normalizing step.
Proof.
  unfold normalizing.
  tm\_cases (induction t) Case.
     Case "C".
       \exists (C n).
       split.
       SCase "l". apply multi_refl.
```

rewrite nf\_same\_as\_value. apply v\_const.

SCase "r".

```
Case "P".
  inversion IHt1 as [t1' H1]; clear IHt1. inversion IHt2 as [t2' H2]; clear IHt2.
  inversion H1 as [H11 \ H12]; clear H1. inversion H2 as [H21 \ H22]; clear H2.
 rewrite nf_{same_as_value} in H12. rewrite nf_{same_as_value} in H22.
  inversion H12 as [n1]. inversion H22 as [n2].
 rewrite \leftarrow H in H11.
 rewrite \leftarrow H0 in H21.
 \exists (C (n1 + n2)).
  split.
    SCase "l".
      apply multi_trans with (P (C n1) t2).
      apply multistep_congr_1. apply H11.
      apply multi_trans with
         (P (C n1) (C n2)).
      apply multistep_congr_2. apply v_const. apply H21.
      apply multi_R. apply ST_PlusConstConst.
    SCase "r".
      rewrite nf_same_as_value. apply v_const. Qed.
```

#### 17.4.3 Equivalence of Big-Step and Small-Step Reduction

Having defined the operational semantics of our tiny programming language in two different styles, it makes sense to ask whether these definitions actually define the same thing! They do, though it takes a little work to show it. (The details are left as an exercise).

```
Exercise: 3 stars (eval__multistep) Theorem eval__multistep : \forall t \ n, t \mid \mid n \rightarrow t =>* C \ n.
```

The key idea behind the proof comes from the following picture: P t1 t2 ==> (by ST\_Plus1) P t1' t2 ==> (by ST\_Plus1) P t1' t2 ==> (by ST\_Plus1) ... P (C n1) t2 ==> (by ST\_Plus2) P (C n1) t2' ==> (by ST\_Plus2) P (C n1) t2'' ==> (by ST\_Plus2) ... P (C n1) (C n2) ==> (by ST\_PlusConstConst) C (n1 + n2) That is, the multistep reduction of a term of the form P t1 t2 proceeds in three phases:

- First, we use  $ST_Plus1$  some number of times to reduce t1 to a normal form, which must (by  $nf_same_as_value$ ) be a term of the form C n1 for some n1.
- Next, we use  $ST_Plus2$  some number of times to reduce t2 to a normal form, which must again be a term of the form C n2 for some n2.
- Finally, we use  $ST_PlusConstConst$  one time to reduce P(C n1)(C n2) to C(n1 + n2).

To formalize this intuition, you'll need to use the congruence lemmas from above (you might want to review them now, so that you'll be able to recognize when they are useful), plus some basic properties of ==>\*: that it is reflexive, transitive, and includes ==>.

#### Proof.

Admitted.

Exercise: 3 stars, advanced (eval\_\_multistep\_inf) Write a detailed informal version of the proof of eval\_\_multistep.

П

For the other direction, we need one lemma, which establishes a relation between single-step reduction and big-step evaluation.

```
Exercise: 3 stars (step__eval) Lemma step__eval : \forall \ t \ t' \ n, t ==> t' \rightarrow t' \mid \mid n \rightarrow t \mid \mid \mid n.

Proof.

intros t \ t' \ n \ Hs. generalize dependent n.

Admitted.
```

The fact that small-step reduction implies big-step is now straightforward to prove, once it is stated correctly.

The proof proceeds by induction on the multip-step reduction sequence that is buried in the hypothesis  $normal\_form\_of\ t\ t$ . Make sure you understand the statement before you start to work on the proof.

```
Exercise: 3 stars (multistep__eval) Theorem multistep__eval : \forall \ t \ t', normal_form_of t \ t' \to \exists \ n, t' = C \ n \land t \ | \ | \ n.

Proof.

Admitted.
```

#### 17.4.4 Additional Exercises

Exercise: 3 stars, optional (interp\_tm) Remember that we also defined big-step evaluation of tms as a function evalF. Prove that it is equivalent to the existing semantics.

Hint: we just proved that eval and multistep are equivalent, so logically it doesn't matter which you choose. One will be easier than the other, though!

```
Theorem evalF_eval : \forall t \ n, evalF t = n \leftrightarrow t \mid \mid n. Proof.
```

 $\begin{array}{c} Admitted. \\ \square \end{array}$ 

Exercise: 4 stars (combined\_properties) We've considered the arithmetic and conditional expressions separately. This exercise explores how the two interact.

Module COMBINED.

```
Inductive tm : Type :=
    C: \mathbf{nat} \to \mathbf{tm}
    P: tm \rightarrow tm \rightarrow tm
   ttrue : tm
    tfalse: tm
   | \mathsf{tif} : \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}.
Tactic Notation "tm_cases" tactic(first) ident(c) :=
  first;
  [Case\_aux \ c \ "C" \ | Case\_aux \ c \ "P"]
  | Case_aux c "ttrue" | Case_aux c "tfalse" | Case_aux c "tif" ].
Inductive value : tm \rightarrow Prop :=
   | v_{\text{-}} const : \forall n, value (C n)
    v_true : value ttrue
   | v_false : value tfalse.
Reserved Notation "t'==>'t' (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_PlusConstConst : \forall n1 n2,
        P(C n1)(C n2) ==> C(n1 + n2)
  | ST_Plus1 : \forall t1 \ t1' \ t2,
        t1 ==> t1' \rightarrow
        P t1 t2 ==> P t1' t2
  | ST_Plus2 : \forall v1 \ t2 \ t2',
        value v1 \rightarrow
        t2 ==> t2' \rightarrow
        P v1 t2 ==> P v1 t2'
  | ST_IfTrue : \forall t1 t2,
        tif ttrue t1 t2 ==> t1
  | ST_IfFalse : \forall t1 t2,
        tif tfalse t1 t2 ==> t2
  \mid ST_If : \forall t1 t1' t2 t3,
        t1 ==> t1' \rightarrow
        tif t1 t2 t3 ==> tif t1' t2 t3
  where " t '==>' t' " := (step t \ t').
Tactic Notation "step_cases" tactic(first) ident(c) :=
```

```
first;
[ Case_aux c "ST_PlusConstConst"
| Case_aux c "ST_Plus1" | Case_aux c "ST_Plus2"
| Case_aux c "ST_IfTrue" | Case_aux c "ST_IfFalse" | Case_aux c "ST_If" ].
```

Earlier, we separately proved for both plus- and if-expressions...

- that the step relation was deterministic, and
- a strong progress lemma, stating that every term is either a value or can take a step.

Prove or disprove these two properties for the combined language.

End COMBINED.

### 17.5 Small-Step Imp

For a more serious example, here is the small-step version of the Imp operational semantics.

The small-step evaluation relations for arithmetic and boolean expressions are straightforward extensions of the tiny language we've been working up to now. To make them easier to read, we introduce the symbolic notations ==>a and ==>b, respectively, for the arithmetic and boolean step relations.

```
Inductive aval : aexp \rightarrow Prop := av_num : \forall n, aval (ANum n).
```

We are not actually going to bother to define boolean values, since they aren't needed in the definition of ==>b below (why?), though they might be if our language were a bit larger (why?).

```
Reserved Notation "t', st'==>a't' "(at level 40, st at level 39).
```

```
\mid AS\_Minus1 : \forall st a1 a1' a2,
     a1 / st ==> a a1' \rightarrow
      (AMinus a1 a2) / st ==>a (AMinus a1' a2)
\mid \mathsf{AS\_Minus2} : \forall st v1 a2 a2',
     aval v1 \rightarrow
      a2 / st ==> a a2' \rightarrow
      (AMinus v1 a2) / st ==>a (AMinus v1 a2')
\mid \mathsf{AS\_Mult} : \forall st \ n1 \ n2,
      (AMult (ANum n1) (ANum n2)) / st ==>a (ANum (mult n1 n2))
| AS_Mult1 : \forall st a1 a1' a2,
      a1 / st ==>a a1' \rightarrow
      (\mathsf{AMult}\ (a1)\ (a2))\ /\ st ==> a\ (\mathsf{AMult}\ (a1')\ (a2))
\mid \mathsf{AS\_Mult2} : \forall st v1 a2 a2',
     aval v1 \rightarrow
      a2 / st ==>a a2' \rightarrow
      (AMult v1 a2) / st ==>a (AMult v1 a2')
  where " t '/' st '==>a' t' " := (astep st \ t').
Reserved Notation "t'/st'==>b't' "(at level 40, st at level 39).
Inductive bstep: state \rightarrow bexp \rightarrow bexp \rightarrow Prop :=
\mid \mathsf{BS}_{\mathsf{Eq}} : \forall st \ n1 \ n2,
      (BEq (ANum n1) (ANum n2)) / st ==>b
      (if (beq_nat n1 n2) then BTrue else BFalse)
\mid \mathsf{BS}_{\mathsf{-}}\mathsf{Eq1} : \forall st \ a1 \ a1' \ a2,
      a1 / st ==> a a1' \rightarrow
      (BEq a1 a2) / st ==>b (BEq a1' a2)
\mid \mathsf{BS}_{\mathsf{Eq2}} : \forall st \ v1 \ a2 \ a2',
     aval v1 \rightarrow
     a2 / st ==>a a2 \rightarrow
      (BEq v1 a2) / st ==>b (BEq v1 a2')
\mid \mathsf{BS\_LtEq} : \forall st \ n1 \ n2,
      (BLe (ANum n1) (ANum n2)) / st ==>b
                   (if (ble_nat n1 n2) then BTrue else BFalse)
\mid \mathsf{BS\_LtEq1} : \forall st \ a1 \ a1' \ a2,
      a1 / st ==> a a1' \rightarrow
      (BLe a1 a2) / st ==>b (BLe a1' a2)
\mid \mathsf{BS\_LtEq2} : \forall \ st \ v1 \ a2 \ a2',
     aval v1 \rightarrow
     a2 / st ==>a a2' \rightarrow
      (BLe v1 a2) / st ==>b (BLe v1 (a2'))
\mid \mathsf{BS\_NotTrue} : \forall st,
      (BNot BTrue) / st ==>b BFalse
```

```
\mid \mathsf{BS\_NotFalse} : \forall st,
      (BNot BFalse) / st ==>b BTrue
\mid \mathsf{BS\_NotStep} : \forall \mathit{st} \ \mathit{b1} \ \mathit{b1'},
      b1 / st ==>b b1' \rightarrow
      (BNot b1) / st ==>b (BNot b1')
\mid \mathsf{BS\_AndTrueTrue} : \forall st,
      (BAnd BTrue BTrue) / st ==>b BTrue
\mid \mathsf{BS\_AndTrueFalse} : \forall st,
      (BAnd BTrue BFalse) / st ==>b BFalse
\mid \mathsf{BS\_AndFalse} : \forall st \ b2,
      (BAnd BFalse b2) / st ==>b BFalse
\mid \mathsf{BS\_AndTrueStep} : \forall st \ b2 \ b2',
      b2 / st ==>b b2' \rightarrow
      (BAnd BTrue b2) / st ==>b (BAnd BTrue b2')
\mid \mathsf{BS\_AndStep} : \forall st \ b1 \ b1' \ b2,
      b1 / st ==>b b1' \rightarrow
      (BAnd b1 b2) / st ==>b (BAnd b1' b2)
where " t '/' st '==>b' t' " := (bstep st \ t').
```

The semantics of commands is the interesting part. We need two small tricks to make it work:

- We use SKIP as a "command value" i.e., a command that has reached a normal form.
  - An assignment command reduces to SKIP (and an updated state).
  - The sequencing command waits until its left-hand subcommand has reduced to SKIP, then throws it away so that reduction can continue with the right-hand subcommand.
- We reduce a WHILE command by transforming it into a conditional followed by the same WHILE.

(There are other ways of achieving the effect of the latter trick, but they all share the feature that the original *WHILE* command needs to be saved somewhere while a single copy of the loop body is being evaluated.)

```
Reserved Notation " t '/' st '==>' t' '/' st' " (at level 40, st at level 39, t' at level 39). Inductive \mathsf{cstep} : (\mathsf{com} \times \mathsf{state}) \to (\mathsf{com} \times \mathsf{state}) \to \mathsf{Prop} := | \mathsf{CS\_AssStep} : \forall st \ i \ a \ a', \\ a \ / \ st \ ==> a \ a' \to \\ (i ::= a) \ / \ st \ ==> (i ::= a') \ / \ st \\ | \mathsf{CS\_Ass} : \forall \ st \ i \ n,
```

```
(i ::= (ANum n)) / st ==> SKIP / (update st i n)
| CS\_SegStep : \forall st c1 c1' st' c2,
     c1 / st ==> c1' / st' \rightarrow
     (c1;;c2) / st ==> (c1';;c2) / st'
\mid \mathsf{CS\_SegFinish} : \forall st \ c2,
     (SKIP;; c2) / st ==> c2 / st
| CS_IfTrue : \forall st c1 c2,
     IFB BTrue THEN c1 ELSE c2 FI / st ==> c1 / st
| CS_IfFalse : \forall st c1 c2,
     IFB BFalse THEN c1 ELSE c2 FI / st ==> c2 / st
| CS_IfStep : \forall st b b' c1 c2,
     b / st ==>b b' \rightarrow
     IFB b THEN c1 ELSE c2 FI / st ==> (IFB b' THEN c1 ELSE c2 FI) / st
\mid \mathsf{CS}_{-}\mathsf{While} : \forall st \ b \ c1,
          (WHILE b DO c1 END) / st
     ==> (IFB b THEN (c1;; (WHILE b DO c1 END)) ELSE SKIP FI) / st
where "t'/'st'==>'t''/'st'" := (cstep (t,st) (t',st')).
```

## 17.6 Concurrent Imp

Finally, to show the power of this definitional style, let's enrich Imp with a new form of command that runs two subcommands in parallel and terminates when both have terminated. To reflect the unpredictability of scheduling, the actions of the subcommands may be interleaved in any order, but they share the same memory and can communicate by reading and writing the same variables.

Module CIMP.

```
Inductive com : Type :=  | \mathsf{CSkip} : \mathsf{com} | \mathsf{CAss} : \mathsf{id} \to \mathsf{aexp} \to \mathsf{com} | \mathsf{CSeq} : \mathsf{com} \to \mathsf{com} \to \mathsf{com} | \mathsf{CSeq} : \mathsf{com} \to \mathsf{com} \to \mathsf{com} \to \mathsf{com} | \mathsf{CHf} : \mathsf{bexp} \to \mathsf{com} \to \mathsf{com} \to \mathsf{com} | \mathsf{CWhile} : \mathsf{bexp} \to \mathsf{com} \to \mathsf{com} | \mathsf{CWhile} : \mathsf{bexp} \to \mathsf{com} \to \mathsf{com} | \mathsf{CPar} : \mathsf{com} \to \mathsf{com} \to \mathsf{com} | \mathsf{CPar} : \mathsf{com} \to \mathsf{com} \to \mathsf{com} | \mathsf{Case} : \mathsf{com} \to \mathsf{com} \to \mathsf{com} | \mathsf{Case} : \mathsf{com} \to \mathsf{com} | \mathsf{Case} : \mathsf{com} \to \mathsf{com} | \mathsf{com} : \mathsf{case} : \mathsf{com} \to \mathsf{com} | \mathsf{com} : \mathsf{case} : \mathsf{com} : \mathsf{com} : \mathsf{com} : \mathsf{case} : \mathsf{com} : \mathsf{com}
```

```

Definition stack_multistep st := multi (stack_step st).
```

Exercise: 3 stars, advanced (compiler\_is\_correct) Remember the definition of *compile* for aexp given in the lmp chapter. We want now to prove *compile* correct with respect to the stack machine.

State what it means for the compiler to be correct according to the stack machine small step semantics and then prove it.

```
Definition compiler_is_correct_statement : Prop := admit.
```

Theorem compiler\_is\_correct: compiler\_is\_correct\_statement.

Proof.

Admitted.

# Chapter 18

# Library Rel

### 18.1 Rel: Properties of Relations

Require Export SfLib.

A (binary) relation is just a parameterized proposition. As you know from your undergraduate discrete math course, there are a lot of ways of discussing and describing relations in general – ways of classifying relations (are they reflexive, transitive, etc.), theorems that can be proved generically about classes of relations, constructions that build one relation from another, etc. Let us pause here to review a few that will be useful in what follows.

A (binary) relation on a set X is a proposition parameterized by two Xs – i.e., it is a logical assertion involving two values from the set X.

```
Definition relation (X: \mathsf{Type}) := X \rightarrow X \rightarrow \mathsf{Prop}.
```

Somewhat confusingly, the Coq standard library hijacks the generic term "relation" for this specific instance. To maintain consistency with the library, we will do the same. So, henceforth the Coq identifier relation will always refer to a binary relation between some set and itself, while the English word "relation" can refer either to the specific Coq concept or the more general concept of a relation between any number of possibly different sets. The context of the discussion should always make clear which is meant.

An example relation on **nat** is **le**, the less-that-or-equal-to relation which we usually write like this  $n1 \le n2$ .

```
Print le.
Check le : nat \rightarrow nat \rightarrow Prop.
Check le : relation nat.
```

## 18.2 Basic Properties of Relations

A relation R on a set X is a partial function if, for every x, there is at most one y such that  $R \times y - i.e.$ , if  $R \times y1$  and  $R \times y2$  together imply y1 = y2.

```
Definition partial_function \{X : \mathtt{Type}\}\ (R : \mathtt{relation}\ X) := \forall x\ y1\ y2 : X,\ R\ x\ y1 \to R\ x\ y2 \to y1 = y2.
```

For example, the **next\_nat** relation defined in Logic.v is a partial function.

However, the < relation on numbers is not a partial function.

This can be shown by contradiction. In short: Assume, for a contradiction, that  $\leq$  is a partial function. But then, since  $0 \leq 0$  and  $0 \leq 1$ , it follows that 0 = 1. This is nonsense, so our assumption was contradictory.

```
Theorem le_not_a_partial_function:

¬ (partial_function le).

Proof.

unfold not. unfold partial_function. intros Hc.

assert (0 = 1) as Nonsense.

Case "Proof of assertion".

apply Hc with (x := 0).

apply le_n.

apply le_S. apply le_n.

inversion Nonsense. Qed.
```

Exercise: 2 stars, optional Show that the total\_relation defined in Logic.v is not a partial function.

**Exercise: 2 stars, optional** Show that the **empty\_relation** defined in Logic.v is a partial function.

A reflexive relation on a set X is one for which every element of X is related to itself.

```
Definition reflexive \{X \colon \mathtt{Type}\}\ (R \colon \mathtt{relation}\ X) := \forall \ a \colon X, \ R \ a \ a. Theorem le_reflexive : reflexive le.
```

Proof.

unfold reflexive. intros n. apply  $e_n$ . Qed.

A relation R is *transitive* if R a c holds whenever R a b and R b c do.

```
Definition transitive \{X \colon \mathtt{Type}\}\ (R \colon \mathtt{relation}\ X) := \forall \ a \ b \ c \colon X, \ (R \ a \ b) \to (R \ b \ c) \to (R \ a \ c).
```

Theorem le\_trans:

transitive le.

Proof.

intros n m o Hnm Hmo.

```
induction Hmo.
  Case "le_n". apply Hnm.
  Case "le_S". apply le_S. apply IHHmo. Qed.
Theorem It_trans:
  transitive It.
Proof.
  unfold It. unfold transitive.
  intros n m o Hnm Hmo.
  apply le_S in Hnm.
  apply le_trans with (a := (S n)) (b := (S m)) (c := o).
  apply Hnm.
  apply Hmo. Qed.
Exercise: 2 stars, optional We can also prove lt_trans more laboriously by induction,
without using le_trans. Do this.
Theorem lt_trans':
  transitive It.
Proof.
  unfold It. unfold transitive.
  intros n m o Hnm Hmo.
  induction Hmo as [|m'Hm'o|].
   Admitted.
   Exercise: 2 stars, optional Prove the same thing again by induction on o.
Theorem lt_trans':
  transitive It.
Proof.
  unfold transitive.
  intros n m o Hnm Hmo.
  induction o as [ | o' ].
   Admitted.
   The transitivity of le, in turn, can be used to prove some facts that will be useful later
(e.g., for the proof of antisymmetry below)...
Theorem le_Sn_le: \forall n \ m, \ S \ n \leq m \rightarrow n \leq m.
Proof.
  intros n m H. apply le_{trans} with (S n).
    apply le_S. apply le_n.
    apply H. Qed.
```

# Exercise: 1 star, optional Theorem $le_S_n : \forall n m$ , $(S n \leq S m) \rightarrow (n \leq m).$ Proof. Admitted. Exercise: 2 stars, optional (le\_Sn\_n\_inf) Provide an informal proof of the following theorem: Theorem: For every n, $(S n \le n)$ A formal proof of this is an optional exercise below, but try the informal proof without doing the formal proof first. Proof: $\square$ Exercise: 1 star, optional Theorem le\_Sn\_n : $\forall n$ , $\neg$ (S n < n). Proof. Admitted. Reflexivity and transitivity are the main concepts we'll need for later chapters, but, for a bit of additional practice working with relations in Coq, here are a few more common ones. A relation R is *symmetric* if R a b implies R b a. Definition symmetric $\{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=$ $\forall a \ b : X, (R \ a \ b) \rightarrow (R \ b \ a).$ Exercise: 2 stars, optional Theorem le\_not\_symmetric: ¬ (symmetric le). Proof. Admitted. A relation R is antisymmetric if R a b and R b a together imply a = b - that is, if the only "cycles" in **R** are trivial ones. Definition antisymmetric $\{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=$ $\forall a \ b : X, (R \ a \ b) \rightarrow (R \ b \ a) \rightarrow a = b.$ Exercise: 2 stars, optional Theorem le\_antisymmetric: antisymmetric le. Proof. Admitted.

```
Exercise: 2 stars, optional Theorem le_step: \forall n \ m \ p,
  n < m \rightarrow
  m \leq S p \rightarrow
  n < p.
Proof.
    Admitted.
    A relation is an equivalence if it's reflexive, symmetric, and transitive.
Definition equivalence \{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=
   (reflexive R) \wedge (symmetric R) \wedge (transitive R).
    A relation is a partial order when it's reflexive, anti-symmetric, and transitive. In the
Cog standard library it's called just "order" for short.
Definition order \{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=
   (reflexive R) \wedge (antisymmetric R) \wedge (transitive R).
    A preorder is almost like a partial order, but doesn't have to be antisymmetric.
Definition preorder \{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=
   (reflexive R) \wedge (transitive R).
Theorem le_order:
  order le.
Proof.
  unfold order. split.
     Case "refl". apply le_reflexive.
     split.
        Case "antisym". apply le_antisymmetric.
        Case "transitive.". apply le_trans. Qed.
```

### 18.3 Reflexive, Transitive Closure

The reflexive, transitive closure of a relation  $\mathbf{R}$  is the smallest relation that contains  $\mathbf{R}$  and that is both reflexive and transitive. Formally, it is defined like this in the Relations module of the Coq standard library:

For example, the reflexive and transitive closure of the **next\_nat** relation coincides with the **le** relation.

```
Theorem next_nat_closure_is_le : \forall n m,
  (n \leq m) \leftrightarrow ((clos\_refl\_trans\ next\_nat)\ n\ m).
Proof.
  intros n m. split.
     Case "->".
       intro H. induction H.
       SCase "le_n". apply rt_refl.
       SCase "le_S".
         apply rt_trans with m. apply IHle. apply rt_step. apply nn.
     Case "<-".
       intro H. induction H.
       SCase "rt_step". inversion H. apply le_S. apply le_n.
       SCase "rt_refl". apply le_n.
       SCase "rt_trans".
         apply le_{trans} with y.
         apply IHclos_refl_trans1.
         apply IHclos_refl_trans2. Qed.
```

The above definition of reflexive, transitive closure is natural – it says, explicitly, that the reflexive and transitive closure of **R** is the least relation that includes **R** and that is closed under rules of reflexivity and transitivity. But it turns out that this definition is not very convenient for doing proofs – the "nondeterminism" of the rt\_trans rule can sometimes lead to tricky inductions.

Here is a more useful definition...

```
Inductive refl_step_closure \{X : \texttt{Type}\}\ (R : \texttt{relation}\ X) : \texttt{relation}\ X := | \texttt{rsc\_refl}: \ \forall \ (x : X), \ \texttt{refl\_step\_closure}\ R \ x \ x | | \texttt{rsc\_step}: \ \forall \ (x \ y \ z : X), \\ R \ x \ y \rightarrow \\ \texttt{refl\_step\_closure}\ R \ y \ z \rightarrow \\ \texttt{refl\_step\_closure}\ R \ x \ z.
```

(Note that, aside from the naming of the constructors, this definition is the same as the **multi** step relation used in many other chapters.)

(The following Tactic Notation definitions are explained in Imp.v. You can ignore them if you haven't read that chapter yet.)

```
Tactic Notation "rt_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c "rt_step" | Case\_aux \ c "rt_refl" | Case\_aux \ c "rt_trans" ].

Tactic Notation "rsc_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c "rsc_refl" | Case\_aux \ c "rsc_step" ].
```

Our new definition of reflexive, transitive closure "bundles" the rt\_step and rt\_trans rules

into the single rule step. The left-hand premise of this step is a single use of R, leading to a much simpler induction principle.

Before we go on, we should check that the two definitions do indeed define the same relation...

First, we prove two lemmas showing that **refl\_step\_closure** mimics the behavior of the two "missing" **clos\_refl\_trans** constructors.

```
Theorem rsc_R : \forall (X:Type) (R:relation X) (x y : X),
         R \ x \ y \rightarrow \mathsf{refl\_step\_closure} \ R \ x \ y.
Proof.
  intros X R x y H.
  apply rsc_step with y. apply H. apply rsc_refl. Qed.
Exercise: 2 stars, optional (rsc_trans)
                                                   Theorem rsc_trans:
  \forall (X:Type) (R: relation X) (x y z : X),
       refl_step_closure R x y \rightarrow
       refl_step_closure R \ y \ z \rightarrow
       refl_step_closure R x z.
Proof.
   Admitted.
   Then we use these facts to prove that the two definitions of reflexive, transitive closure
do indeed define the same relation.
Exercise: 3 stars, optional (rtc_rsc_coincide) Theorem rtc_rsc_coincide:
           \forall (X:\mathsf{Type}) (R:\mathsf{relation}\ X) (x\ y:X),
  clos_refl_trans R x y \leftrightarrow \text{refl\_step\_closure } R x y.
Proof.
    Admitted.
```

# Chapter 19

# Library HoareAsLogic

## 19.1 HoareAsLogic: Hoare Logic as a Logic

Require Export Hoare.

The presentation of Hoare logic in chapter Hoare could be described as "model-theoretic": the proof rules for each of the constructors were presented as *theorems* about the evaluation behavior of programs, and proofs of program correctness (validity of Hoare triples) were constructed by combining these theorems directly in Coq.

Another way of presenting Hoare logic is to define a completely separate proof system – a set of axioms and inference rules that talk about commands, Hoare triples, etc. – and then say that a proof of a Hoare triple is a valid derivation in *that* logic. We can do this by giving an inductive definition of *valid derivations* in this new logic.

```
Inductive hoare_proof : Assertion \rightarrow com \rightarrow Assertion \rightarrow Type :=
   \mid \mathsf{H\_Skip} : \forall P,
         hoare_proof P (SKIP) P
   \mid \mathsf{H}_{\mathsf{A}}\mathsf{sgn} : \forall \ Q \ V \ a,
         hoare_proof (assn_sub V a Q) (V ::= a) Q
   \mid \mathsf{H\_Seq} : \forall \ P \ c \ Q \ d \ R,
         hoare_proof P \ c \ Q \to \mathsf{hoare\_proof} \ Q \ d \ R \to \mathsf{hoare\_proof} \ P \ (c;;d) \ R
   \mid \mathsf{H}_{\mathsf{-}}\mathsf{If} : \forall P \ Q \ b \ c1 \ c2,
      hoare_proof (fun st \Rightarrow P \ st \land bassn \ b \ st) \ c1 \ Q \rightarrow
      hoare_proof P (IFB b THEN c1 ELSE c2 FI) Q
   \mid \mathsf{H}_{-}\mathsf{While} : \forall P \ b \ c,
      hoare_proof (fun st \Rightarrow P \ st \land bassn \ b \ st) \ c \ P \rightarrow
      hoare_proof P (WHILE b DO c END) (fun st \Rightarrow P st \land \neg (bassn b st))
   \mid \mathsf{H}_{-}\mathsf{Consequence} : \forall (P \ Q \ P' \ Q' : \mathsf{Assertion}) \ c,
      hoare_proof P' \ c \ Q' \rightarrow
      (\forall st, P st \rightarrow P' st) \rightarrow
```

```
(\forall \ st, \ Q' \ st \rightarrow Q \ st) \rightarrow \\ \textbf{hoare\_proof} \ P \ c \ Q. Tactic Notation "hoare\_proof\_cases" tactic(\texttt{first}) \ ident(c) := \\ \texttt{first}; [\ \textit{Case\_aux} \ c \ "H\_Skip" \ | \ \textit{Case\_aux} \ c \ "H\_Asgn" \ | \ \textit{Case\_aux} \ c \ "H\_Seq" \\ | \ \textit{Case\_aux} \ c \ "H\_If" \ | \ \textit{Case\_aux} \ c \ "H\_While" \ | \ \textit{Case\_aux} \ c \ "H\_Consequence" \ ].
```

We don't need to include axioms corresponding to hoare\_consequence\_pre or hoare\_consequence\_post, because these can be proven easily from H\_Consequence.

```
 \begin{array}{l} \mathsf{Lemma} \ \mathsf{H\_Consequence\_pre} : \forall \ (P \ Q \ P' : \mathsf{Assertion}) \ c, \\ \mathbf{hoare\_proof} \ P' \ c \ Q \rightarrow \\ (\forall \ st, \ P \ st \rightarrow P' \ st) \rightarrow \\ \mathbf{hoare\_proof} \ P \ c \ Q. \\ \\ \mathsf{Proof}. \\ Admitted. \\ \\ \mathsf{Lemma} \ \mathsf{H\_Consequence\_post} : \forall \ (P \ Q \ Q' : \mathsf{Assertion}) \ c, \\ \mathbf{hoare\_proof} \ P \ c \ Q' \rightarrow \\ (\forall \ st, \ Q' \ st \rightarrow Q \ st) \rightarrow \\ \mathbf{hoare\_proof} \ P \ c \ Q. \\ \\ \mathsf{Proof}. \\ \\ \mathsf{Proof}. \\ \end{array}
```

Admitted.

Now, for example, let's construct a proof object representing a derivation for the hoare triple  $^1$  X::=X+1;; X::=X+2  $^2$ . We can use Coq's tactics to help us construct the proof object.

Example sample\_proof

```
: hoare_proof
```

```
(assn_sub X (APlus (Ald X) (ANum 1))

(assn_sub X (APlus (Ald X) (ANum 2))

(fun st \Rightarrow st X = 3))

(X ::= APlus (Ald X) (ANum 1);; (X ::= APlus (Ald X) (ANum 2)))

(fun st \Rightarrow st X = 3).
```

Proof.

eapply  $H\_Seq$ ; apply  $H\_Asgn$ . Qed.

Exercise: 2 stars (hoare\_proof\_sound) Prove that such proof objects represent true claims.

Theorem hoare\_proof\_sound :  $\forall P \ c \ Q$ , hoare\_proof  $P \ c \ Q \rightarrow \{\{P\}\} \ c \ \{\{Q\}\}\}$ .

<sup>&</sup>lt;sup>1</sup>assn\_subX(X+1)(assn\_subX(X+2)(X=3))

```
Proof. Admitted. \Box
```

We can also use Coq's reasoning facilities to prove metatheorems about Hoare Logic. For example, here are the analogs of two theorems we saw in chapter Hoare – this time expressed in terms of the syntax of Hoare Logic derivations (provability) rather than directly in terms of the semantics of Hoare triples.

The first one says that, for every P and c, the assertion  $\{\{P\}\}$  c  $\{\{True\}\}$  is provable in Hoare Logic. Note that the proof is more complex than the semantic proof in Hoare: we actually need to perform an induction over the structure of the command c.

```
Theorem H_Post_True_deriv:

As a last step, we can show that the set of **hoare\_proof** axioms is sufficient to prove any true fact about (partial) correctness. More precisely, any semantic Hoare triple that we can prove can also be proved from these axioms. Such a set of axioms is said to be *relatively complete*.

Qed.

This proof is inspired by the one at http://www.ps.uni-saarland.de/courses/sem-ws11/script/Hoare.html.

To prove this fact, we'll need to invent some intermediate assertions using a technical device known as weakest preconditions. Given a command c and a desired postcondition assertion Q, the weakest precondition wp c Q is an assertion P such that  $\{\{P\}\}\}$  c  $\{\{Q\}\}\}$  holds, and moreover, for any other assertion P', if  $\{\{P'\}\}\}$  c  $\{\{Q\}\}\}$  holds then  $P' \to P$ . We can more directly define this as follows:

```
Definition wp (c:\mathbf{com}) (Q:Assertion): Assertion :=
  fun s \Rightarrow \forall s', c / s \mid \mid s' \rightarrow Q s'.
Exercise: 1 star (wp_is_precondition) Lemma wp_is_precondition: \forall c \ Q,
  \{\{\text{wp } c \ Q\}\}\}\ c \ \{\{Q\}\}\}.
    Admitted.
Exercise: 1 star (wp_is_weakest) Lemma wp_is_weakest: \forall c \ Q \ P',
   \{\{P'\}\}\ c\ \{\{Q\}\}\ \rightarrow \ \forall\ st,\ P'\ st\ \rightarrow \ \mathsf{wp}\ c\ Q\ st.
   Admitted.
   The following utility lemma will also be useful.
Lemma bassn_eval_false : \forall b st, \neg bassn b st \rightarrow beval st b = false.
Proof.
  intros b st H. unfold bassn in H. destruct (beval st b).
     exfalso. apply H. reflexivity.
    reflexivity.
Qed.
Exercise: 4 stars (hoare_proof_complete) Complete the proof of the theorem.
Theorem hoare_proof_complete: \forall P \ c \ Q,
  \{\{P\}\}\ c\ \{\{Q\}\}\} \to \mathsf{hoare\_proof}\ P\ c\ Q.
Proof.
  intros P c. generalize dependent P.
  com_cases (induction c) Case; intros P Q HT.
  Case "SKIP".
     eapply H_Consequence.
      eapply H_Skip.
       intros. eassumption.
       intro st. apply HT. apply E_Skip.
  Case "::=".
     eapply H_Consequence.
       eapply H_Asgn.
       intro st. apply HT. econstructor. reflexivity.
       intros; assumption.
  Case ";;".
     apply H_{-}Seq with (wp c2 Q).
      eapply IHc1.
        intros st st' E1 H. unfold wp. intros st'' E2.
           eapply HT. econstructor; eassumption. assumption.
      eapply IHc2. intros st st ' E1 H. apply H; assumption.
    Admitted.
```

Finally, we might hope that our axiomatic Hoare logic is *decidable*; that is, that there is an (terminating) algorithm (a *decision procedure*) that can determine whether or not a given Hoare triple is valid (derivable). But such a decision procedure cannot exist!

Consider the triple  $\{\{True\}\}\}$  c  $\{\{False\}\}\}$ . This triple is valid if and only if c is non-terminating. So any algorithm that could determine validity of arbitrary triples could solve the Halting Problem.

Similarly, the triple  $\{\{True\}\ SKIP\ \{\{P\}\}\}\$ is valid if and only if  $\forall$  s, P s is valid, where P is an arbitrary assertion of Coq's logic. But it is known that there can be no decision procedure for this logic.

Overall, this axiomatic style of presentation gives a clearer picture of what it means to "give a proof in Hoare logic." However, it is not entirely satisfactory from the point of view of writing down such proofs in practice: it is quite verbose. The section of chapter Hoare2 on formalizing decorated programs shows how we can do even better.

# Chapter 20

# Library HoareList

## 20.1 HoareList: Hoare Logic with Lists

Require Export SfLib.

## 20.2 Imp Programs with Lists

There are only so many numeric functions with interesting properties that have simple proofs. (Of course, there are lots of interesting functions on numbers and they have many interesting properties – this is the whole field of number theory! – but proving these properties often requires developing a lot of supporting lemmas.) In order to able to write a few more programs to reason about, we introduce here an extended version of Imp where variables can range over both numbers and lists of numbers. The basic operations are extended to also include taking the head and tail of lists, and testing lists for nonemptyness.

To do this, we only need to change the definitions of state, aexp, aeval, bexp, and beval. The definitions of **com** and **ceval** can be reused verbatim, although we need to copy-and-paste them in the context of the new definitions.

We start by repeating some material from chapter Imp.

## 20.2.1 Repeated Definitions

```
Inductive id: Type := ld: nat \rightarrow id.

Theorem eq_id_dec : \forall id1 \ id2: id, \{id1 = id2\} + \{id1 \neq id2\}.

Proof.

intros id1 \ id2.

destruct id1 as [n1]. destruct id2 as [n2].

destruct (eq_nat_dec \ n1 \ n2) as [Heq \mid Hneq].

Case \ "n1 = n2".
```

```
left. rewrite Heq. reflexivity.
   Case "n1 <> n2".
     right. intros contra. inversion contra. apply Hneq. apply H0.
Defined.
Lemma eq_id : \forall (T:Type) x (p q:T),
                (if eq_id_dec x x then p else q) = p.
Proof.
  intros.
  destruct (eq_id_dec x x).
  Case "x = x".
    reflexivity.
  Case "x \ll x (impossible)".
    apply ex_falso_quodlibet; apply n; reflexivity. Qed.
Lemma neq_id: \forall (T:Type) \ x \ y \ (p \ q:T), \ x \neq y \rightarrow
                 (if eq_id_dec x y then p else q) = q.
Proof.
  intros.
  destruct (eq_id_dec x y).
  Case "x = y (impossible)".
    subst. apply ex_falso_quodlibet; apply H; reflexivity.
  Case "x \ll y".
    reflexivity. Qed.
Definition X : id := Id 0.
Definition Y : id := Id 1.
Definition Z : id := Id 2.
```

#### 20.2.2 Extensions

Now we come to the key changes.

Rather than evaluating to a **nat**, an **aexp** in our new language will evaluate to a *value* – an element of type **val** – which can be either a **nat** or a list of **nat**s.

Similarly, states will now map identifiers to **val**s rather than **nat**s, so that we can store lists in mutable variables.

Imp does not have a static type system, so nothing prevents the programmer from e.g. adding two lists or taking the head of a number. We have to decide what to do in such nonsensical situations.

We adopt a simple solution: if an arithmetic function is given a list as an argument we treat the list as if it was the number 0. Similarly, if a list function is given a number as an argument we treat the number as if it was nil. (Cf. Javascript, where adding 3 to the empty list evaluates to 3...)

The two functions asnat and aslist interpret vals in a numeric or a list context; aeval calls these whenever it evaluates an arithmetic or a list operation.

```
Definition asnat (v: \mathbf{val}): \mathbf{nat} := \max v \text{ with } | \mathsf{VNat} \ n \Rightarrow n | \mathsf{VList} \ _ \Rightarrow 0 | \text{ end.}
Definition as list (v: \mathbf{val}): \mathsf{list} \ \mathsf{nat} := \max v \text{ with } | \mathsf{VNat} \ n \Rightarrow [] | \mathsf{VList} \ xs \Rightarrow xs | \text{ end.}
```

Now we fill in the definitions of abstract syntax and evaluation functions for arithmetic and boolean expressions.

```
Inductive aexp : Type :=
   ANum : nat \rightarrow aexp
    Ald : id \rightarrow aexp
    APlus : aexp \rightarrow aexp \rightarrow aexp
    \mathsf{AMinus}: \mathbf{aexp} \to \mathbf{aexp} \to \mathbf{aexp}
   AMult : aexp \rightarrow aexp \rightarrow aexp
   AHead : aexp \rightarrow aexp
    ATail : aexp \rightarrow aexp
    ACons : aexp \rightarrow aexp \rightarrow aexp
   | ANil : aexp.
Tactic Notation "aexp\_cases" tactic(first) ident(c) :=
  first;
  [ Case\_aux\ c "ANum" | Case\_aux\ c "AId" | Case\_aux\ c "APlus"
    Case_aux c "AMinus" | Case_aux c "AMult"
    Case_aux c "AHead" | Case_aux c "ATail"
   Case\_aux \ c "ACons" | Case\_aux \ c "ANil" ].
Definition tail (l : list nat) :=
  match l with
  |x::xs \Rightarrow xs
```

```
| [] \Rightarrow []
  end.
Definition head (l : list nat) :=
  \mathtt{match}\ l with
   |x::xs\Rightarrow x
  \mid \square \Rightarrow 0
  end.
Fixpoint aeval (st : state) (e : aexp) : val :=
  match e with
    ANum n \Rightarrow VNat n
    Ald i \Rightarrow st i
    APlus a1 a2 \Rightarrow VNat (asnat (aeval st a1) + asnat (aeval st a2))
    AMinus a1 a2 \Rightarrow VNat (asnat (aeval st a1) – asnat (aeval st a2))
   AMult a1 a2 \Rightarrow VNat (asnat (aeval st a1) \times asnat (aeval st a2))
   | ATail a \Rightarrow VList (tail (aslist (aeval st a)))
    AHead a \Rightarrow VNat (head (aslist (aeval <math>st \ a)))
    ACons a1 a2 \Rightarrow VList (asnat (aeval st a1) :: aslist (aeval st a2))
   ANil \Rightarrow VList
  end.
    We extend bexps with an operation to test if a list is nonempty and adapt beval acord-
ingly.
Inductive bexp: Type :=
    BTrue : bexp
    BFalse: bexp
    \mathsf{BEq}: \mathsf{aexp} \to \mathsf{aexp} \to \mathsf{bexp}
    BLe : aexp \rightarrow aexp \rightarrow bexp
    \mathsf{BNot}: \mathbf{bexp} \to \mathbf{bexp}
    \mathsf{BAnd}: \mathbf{bexp} \to \mathbf{bexp} \to \mathbf{bexp}
  | BlsCons : aexp \rightarrow bexp.
Tactic Notation "bexp_cases" tactic(first) ident(c) :=
  first;
  [ Case\_aux\ c "BTrue" | Case\_aux\ c "BFalse" | Case\_aux\ c "BEq"
    Case_aux c "BLe" | Case_aux c "BNot" | Case_aux c "BAnd"
   | Case\_aux \ c "BIsCons" |.
Fixpoint beval (st : state) (e : bexp) : bool :=
  {\tt match}\ e\ {\tt with}
    BTrue \Rightarrow true
    BFalse \Rightarrow false
   | BEq a1 a2 \Rightarrow beq_nat (asnat (aeval st a1)) (asnat (aeval st a2))
```

```
| BLe a1 a2 \Rightarrow ble_nat (asnat (aeval st a1)) (asnat (aeval st a2)) | BNot b1 \Rightarrow negb (beval st b1) | BAnd b1 b2 \Rightarrow andb (beval st b1) (beval st b2) | BIsCons a \Rightarrow match aslist (aeval st a) with | _::_ \Rightarrow true | [] \Rightarrow false end.
```

### 20.2.3 Repeated Definitions

Now we need to repeat a little bit of low-level work from Imp.v, plus the definitions of **com** and **ceval**. There are no interesting changes – it's just a matter of repeating the same definitions, lemmas, and proofs in the context of the new definitions of arithmetic and boolean expressions.

(Is all this cutting and pasting really necessary? No: Coq includes a powerful module system that we could use to abstract the repeated definitions with respect to the varying parts. But explaining how it works would distract us from the topic at hand.)

```
Theorem update_eq : \forall n \ V \ st,
  (update st \ V \ n) V = n.
Proof.
  intros n \ V \ st.
  unfold update.
  rewrite eq_id.
  reflexivity.
Qed.

#### 20.3.1Reasoning About Programs with Lists

Now let's look at a formal Hoare Logic proof for a program that works with lists. We will verify the following program, which checks if the number Y occurs in the list X, and if so sets Z to 1.

```
Definition list_member :=
  WHILE BIsCons (Ald X) DO
    IFB (BEq (Ald Y) (AHead (Ald X))) THEN
      Z ::= (ANum 1)
    ELSE
      SKIP
    FI;
    X ::= ATail (Ald X)
  END.
   The informal proof looks like this: ^{25} = ^{26} WHILE (BIsCons X) DO ^{27} IFB (Y ==
 ^{25}X=1/\Y=n/\Z=0
```

 $<sup>^{26}</sup>$ Y=n/\existsp,p++X=1/\(Z=1<->appears\_innp)

 $<sup>^{27}</sup>$ Y=n/\(existsp,p++X=1/\(Z=1<->appears\_innp))/\(BIsConsX)

```
head X) THEN ^{28} = > ^{29} Z ::= 1 ^{30} ELSE ^{31} = > ^{32} SKIP ^{33} FI; ^{34} X ::= ATail X ^{35} END ^{36} = > ^{37}
```

The only interesting part of the proof is the choice of loop invariant: exists p, p ++ X =  $l / (Z = 1 <-> appears_in n p)$  This states that at each iteration of the loop, the original list l is equal to the append of the current value of X and some other list p which is not the value of any variable in the program, but keeps track of enough information from the original state to make the proof go through. (Such a p is sometimes called a "ghost variable").

In order to show that such a list p exists, in each iteration we add the head of X to the end of p. This needs the function snoc, from Poly.v.

```
Fixpoint snoc \{X: \mathsf{Type}\}\ (l: \mathsf{list}\ X)\ (v:X): (\mathsf{list}\ X) :=
      match l with
      | \mathsf{nil} \Rightarrow [v]
      |\cos h| t \Rightarrow h :: (\operatorname{snoc} t| v)
      end.
          The main proof uses several lemmas about snoc and ++.
Lemma snoc_equation : \forall (A : Type) (h:A) (x y : list A),
      snoc x \ h ++ y = x ++ h :: y.
Proof.
      intros A h x y.
      induction x.
              Case "x = []". reflexivity.
              Case "x = cons". simpl. rewrite IHx. reflexivity.
Qed.
Lemma appears_in_snoc1 : \forall a l,
      appears_in a (snoc l a).
Proof.

Exercise: 3 stars (list\_sum) Here is a direct definition of the sum of the elements of a list, and an Imp program that computes the sum.

```
Definition sum l := \mathsf{fold\_right} \ \mathsf{plus} \ 0 \ l.
```

```
Definition sum_program :=
  Y ::= ANum 0;
WHILE (BlsCons (Ald X)) D0
  Y ::= APlus (Ald Y) (AHead (Ald X));
  X ::= ATail (Ald X)
END.
```

Provide an *informal* proof of the following specification of sum\_program in the form of a decorated version of the program.

Exercise: 4 stars (list\_reverse) Recall the function rev from Poly.v, for reversing lists.

```
Fixpoint rev \{X: \texttt{Type}\}\ (l: \texttt{list}\ X): \texttt{list}\ X := \texttt{match}\ l \ \texttt{with} |\ \texttt{nil}\ \Rightarrow\ [] |\ \texttt{cons}\ h\ t \Rightarrow \texttt{snoc}\ (\texttt{rev}\ t)\ h end.
```

Write an Imp program *list\_reverse\_program* that reverses lists. Formally prove that it satisfies the following specification: forall l: list nat, <sup>38</sup> list\_reverse\_program <sup>39</sup>. You may find the lemmas append\_nil and rev\_equation useful.

Finally, for a bigger example, let's redo the proof of list\_member\_correct from above using our new tools.

Notice that the *verify* tactic leaves subgoals for each "interesting" use of hoare\_consequence – that is, for each  $\Rightarrow$  that occurs in the decorated program, except for the ones that can be eliminated by repeated application of a few simple automated tactics. Each of these implications relies on a fact about lists, for example that I ++ [] = I. In other words, the Hoare logic infrastructure has taken care of the boilerplate reasoning about the execution of imperative programs, while the user has to prove lemmas that are specific to the problem domain (e.g. lists or numbers).

# Library Hoare2

## 21.1 Hoare 2: Hoare Logic, Part II

Require Export Hoare.

## 21.2 Decorated Programs

The beauty of Hoare Logic is that it is *compositional* – the structure of proofs exactly follows the structure of programs. This suggests that we can record the essential ideas of a proof informally (leaving out some low-level calculational details) by decorating programs with appropriate assertions around each statement. Such a *decorated program* carries with it an (informal) proof of its own correctness.

For example, here is a complete decorated program:

```
^1 -» ^2 X ::= m; ^3 -» ^4 Z ::= p; ^5 -» ^6 WHILE X <> 0 DO ^7 -» ^8 Z ::= Z - 1; ^9 X ::= X - 1 ^{10} END; ^{11} -» ^{12} -»
```

Concretely, a decorated program consists of the program text interleaved with assertions. To check that a decorated program represents a valid proof, we check that each individual command is *locally consistent* with its accompanying assertions in the following sense:

```
1True
2m=m
3X=m
4X=m/\p=p
5X=m/\Z=p
6Z-X=p-m
7Z-X=p-m/\X<>0
8(Z-1)-(X-1)=p-m
9Z-(X-1)=p-m
10Z-X=p-m
11Z-X=p-m/\~(X<>0)
12Z=p-m
```

- $\bullet$  SKIP is locally consistent if its precondition and postcondition are the same:  $^{13}$  SKIP  $^{14}$
- The sequential composition of c1 and c2 is locally consistent (with respect to assertions P and R) if c1 is locally consistent (with respect to P and Q) and c2 is locally consistent (with respect to Q and R): <sup>15</sup> c1; <sup>16</sup> c2 <sup>17</sup>
- An assignment is locally consistent if its precondition is the appropriate substitution of its postcondition:  $^{18}$  X ::=  $a^{19}$
- A conditional is locally consistent (with respect to assertions P and Q) if the assertions at the top of its "then" and "else" branches are exactly P  $\wedge$  b and P  $\wedge$  ¬b and if its "then" branch is locally consistent (with respect to P  $\wedge$  b and Q) and its "else" branch is locally consistent (with respect to P  $\wedge$  ¬b and Q): <sup>20</sup> IFB b THEN <sup>21</sup> c1 <sup>22</sup> ELSE <sup>23</sup> c2 <sup>24</sup> FI <sup>25</sup>
- A while loop with precondition P is locally consistent if its postcondition is P  $\land \neg b$  and if the pre- and postconditions of its body are exactly P  $\land b$  and P: <sup>26</sup> WHILE b DO <sup>27</sup> c1 <sup>28</sup> END <sup>29</sup>
- A pair of assertions separated by -» is locally consistent if the first implies the second (in all states):  $^{30}$  -»  $^{31}$

This corresponds to the application of hoare\_consequence and is the only place in a decorated program where checking if decorations are correct is not fully mechanical and syntactic, but involves logical and/or arithmetic reasoning.

We have seen above how *verifying* the correctness of a given proof involves checking that every single command is locally consistent with the accompanying assertions. If we are

```

<sup>22</sup>Q
<sup>23</sup>P/\~b
^{24}
^{25}Q
26p
<sup>27</sup>P/\b
<sup>29</sup>P/\~b
30p
31p;
```

instead interested in *finding* a proof for a given specification we need to discover the right assertions. This can be done in an almost automatic way, with the exception of finding loop invariants, which is the subject of in the next section. In the reminder of this section we explain in detail how to construct decorations for several simple programs that don't involve non-trivial loop invariants.

#### 21.2.1 Example: Swapping Using Addition and Subtraction

Here is a program that swaps the values of two variables using addition and subtraction (instead of by assigning to a temporary variable). X := X + Y; Y := X - Y; X := X - Y We can prove using decorations that this program is correct – i.e., it always swaps the values of variables X and Y.

(1)  $^{32}$  -» (2)  $^{33}$  X ::= X + Y; (3)  $^{34}$  Y ::= X - Y; (4)  $^{35}$  X ::= X - Y (5)  $^{36}$  The decorations were constructed as follows:

- We begin with the undecorated program (the unnumbered lines).
- We then add the specification i.e., the outer precondition (1) and postcondition (5). In the precondition we use auxiliary variables (parameters) m and n to remember the initial values of variables X and respectively Y, so that we can refer to them in the postcondition (5).
- We work backwards mechanically starting from (5) all the way to (2). At each step, we obtain the precondition of the assignment from its postcondition by substituting the assigned variable with the right-hand-side of the assignment. For instance, we obtain (4) by substituting X with X Y in (5), and (3) by substituting Y with X Y in (4).
- Finally, we verify that (1) logically implies (2) i.e., that the step from (1) to (2) is a valid use of the law of consequence. For this we substitute X by m and Y by n and calculate as follows: (m+n) ((m+n) n) = n / m = m = n / m = m

(Note that, since we are working with natural numbers, not fixed-size machine integers, we don't need to worry about the possibility of arithmetic overflow anywhere in this argument.)

 $<sup>^{32}</sup>$ X=m/\Y=n

 $<sup>^{33}(</sup>X+Y)-((X+Y)-Y)=n/(X+Y)-Y=m$ 

 $<sup>^{34}</sup>X-(X-Y)=n/X-Y=m$ 

 $<sup>^{35}</sup>$ X-Y=n/\Y=m

 $<sup>^{36}</sup>X=n/Y=m$ 

### 21.2.2 Example: Simple Conditionals

Here is a simple decorated program using conditionals: (1)  $^{37}$  IFB X <= Y THEN (2)  $^{38}$  -» (3)  $^{39}$  Z ::= Y - X (4)  $^{40}$  ELSE (5)  $^{41}$  -» (6)  $^{42}$  Z ::= X - Y (7)  $^{43}$  FI (8)  $^{44}$  These decorations were constructed as follows:

- We start with the outer precondition (1) and postcondition (8).
- We follow the format dictated by the hoare\_if rule and copy the postcondition (8) to (4) and (7). We conjoin the precondition (1) with the guard of the conditional to obtain (2). We conjoin (1) with the negated guard of the conditional to obtain (5).
- In order to use the assignment rule and obtain (3), we substitute Z by Y X in (4). To obtain (6) we substitute Z by X Y in (7).
- Finally, we verify that (2) implies (3) and (5) implies (6). Both of these implications crucially depend on the ordering of X and Y obtained from the guard. For instance, knowing that  $X \leq Y$  ensures that subtracting X from Y and then adding back X produces Y, as required by the first disjunct of (3). Similarly, knowing that  $\tilde{\ }(X \leq Y)$  ensures that subtracting Y from X and then adding back Y produces X, as needed by the second disjunct of (6). Note that n m + m = n does *not* hold for arbitrary natural numbers n and m (for example, 3 5 + 5 = 5).

Exercise: 2 stars (if\_minus\_plus\_reloaded) Fill in valid decorations for the following program:  $^{45}$  IFB X <= Y THEN  $^{46}$  -»  $^{47}$  Z ::= Y - X  $^{48}$  ELSE  $^{49}$  -»  $^{50}$  Y ::= X + Z  $^{51}$  FI  $^{52}$ 

```
37True
^{38}True/\X<=Y
^{39}(Y-X)+X=Y\setminus/(Y-X)+Y=X
^{40}Z+X=Y\setminus Z+Y=X
<sup>41</sup>True/\~(X<=Y)
^{42}(X-Y)+X=Y\setminus/(X-Y)+Y=X
^{43}Z+X=Y\setminus /Z+Y=X
^{44}Z+X=Y\setminus /Z+Y=X
^{45} {\tt True}
46
47
48
49
50
51
^{52}Y=X+Z
```

### 21.2.3 Example: Reduce to Zero (Trivial Loop)

Here is a *WHILE* loop that is so simple it needs no invariant (i.e., the invariant **True** will do the job). (1)  $^{53}$  WHILE X <> 0 DO (2)  $^{54}$  -» (3)  $^{55}$  X ::= X - 1 (4)  $^{56}$  END (5)  $^{57}$  -» (6)  $^{58}$  The decorations can be constructed as follows:

- Start with the outer precondition (1) and postcondition (6).
- Following the format dictated by the hoare\_while rule, we copy (1) to (4). We conjoin (1) with the guard to obtain (2) and with the negation of the guard to obtain (5). Note that, because the outer postcondition (6) does not syntactically match (5), we need a trivial use of the consequence rule from (5) to (6).
- Assertion (3) is the same as (4), because X does not appear in 4, so the substitution in the assignment rule is trivial.
- Finally, the implication between (2) and (3) is also trivial.

From this informal proof, it is easy to read off a formal proof using the Coq versions of the Hoare rules. Note that we do *not* unfold the definition of hoare\_triple anywhere in this proof – the idea is to use the Hoare rules as a "self-contained" logic for reasoning about programs.

```
Definition reduce_to_zero': com :=
  WHILE BNot (BEq (Ald X) (ANum 0)) DO
    X ::= AMinus (Ald X) (ANum 1)
  END.

apply beq_nat_true in GuardFalse.
apply GuardFalse. Qed.
```

### 21.2.4 Example: Division

The following Imp program calculates the integer division and remainder of two numbers m and n that are arbitrary constants in the program. X := m; Y := 0; WHILE n <= X DO X := X - n; Y := Y + 1 END; In other words, if we replace m and n by concrete numbers and execute the program, it will terminate with the variable X set to the remainder when m is divided by n and Y set to the quotient.

In order to give a specification to this program we need to remember that dividing m by n produces a reminder X and a quotient Y so that  $n \times Y + X = m \wedge X > n$ .

It turns out that we get lucky with this program and don't have to think very hard about the loop invariant: the invariant is the just first conjunct  $n \times Y + X = m$ , so we use that to decorate the program.

```
(1) ^{59} -» (2) ^{60} X ::= m; (3) ^{61} Y ::= 0; (4) ^{62} WHILE n <= X DO (5) ^{63} -» (6) ^{64} X ::= X - n; (7) ^{65} Y ::= Y + 1 (8) ^{66} END (9) ^{67}
```

Assertions (4), (5), (8), and (9) are derived mechanically from the invariant and the loop's guard. Assertions (8), (7), and (6) are derived using the assignment rule going backwards from (8) to (6). Assertions (4), (3), and (2) are again backwards applications of the assignment rule.

Now that we've decorated the program it only remains to check that the two uses of the consequence rule are correct – i.e., that (1) implies (2) and that (5) implies (6). This is indeed the case, so we have a valid decorated program.

```
59True
60n*0+m=m
61n*0+X=m
62n*Y+X=m
63n*Y+X=m/\n<=X
64n*(Y+1)+(X-n)=m
65n*(Y+1)+X=m
66n*Y+X=m
67n*Y+X=m/\X<n
```

## 21.3 Finding Loop Invariants

Once the outermost precondition and postcondition are chosen, the only creative part in verifying programs with Hoare Logic is finding the right loop invariants. The reason this is difficult is the same as the reason that doing inductive mathematical proofs requires creativity: strengthening the loop invariant (or the induction hypothesis) means that you have a stronger assumption to work with when trying to establish the postcondition of the loop body (complete the induction step of the proof), but it also means that the loop body postcondition itself is harder to prove!

This section is dedicated to teaching you how to approach the challenge of finding loop invariants using a series of examples and exercises.

#### 21.3.1 Example: Slow Subtraction

The following program subtracts the value of X from the value of Y by repeatedly decrementing both X and Y. We want to verify its correctness with respect to the following specification:

68 WHILE X <> 0 DO Y ::= Y - 1; X ::= X - 1 END 69

To verify this program we need to find an invariant I for the loop. As a first step we can leave I as an unknown and build a *skeleton* for the proof by applying backward the rules for local consistency. This process leads to the following skeleton: (1)  $^{70}$  -» (a) (2)  $^{71}$  WHILE X <> 0 DO (3)  $^{72}$  -» (c) (4)  $^{73}$  Y ::= Y - 1; (5)  $^{74}$  X ::= X - 1 (6)  $^{75}$  END (7)  $^{76}$  -» (b) (8)  $^{77}$ 

By examining this skeleton, we can see that any valid I will have to respect three conditions:

- (a) it must be weak enough to be implied by the loop's precondition, i.e. (1) must imply (2);
- (b) it must be strong enough to imply the loop's postcondition, i.e. (7) must imply (8);
- (c) it must be preserved by one iteration of the loop, i.e. (3) must imply (4).

These conditions are actually independent of the particular program and specification we are considering. Indeed, every loop invariant has to satisfy them. One way to find an invariant that simultaneously satisfies these three conditions is by using an iterative process:

```
68 X=m/\Y=n
69 Y=n-m
70 X=m/\Y=n
71 I
72 I/\X<>0
73 I [X|->X-1] [Y|->Y-1]
74 I [X|->X-1]
75 I
76 I/\~(X<>0)
77 Y=n-m
```

start with a "candidate" invariant (e.g. a guess or a heuristic choice) and check the three conditions above; if any of the checks fails, try to use the information that we get from the failure to produce another (hopefully better) candidate invariant, and repeat the process.

For instance, in the reduce-to-zero example above, we saw that, for a very simple loop, choosing **True** as an invariant did the job. So let's try it again here! I.e., let's instantiate with **True** in the skeleton above see what we get... (1)  $^{78}$  -» (a - OK) (2)  $^{79}$  WHILE X <> 0 DO (3)  $^{80}$  -» (c - OK) (4)  $^{81}$  Y ::= Y - 1; (5)  $^{82}$  X ::= X - 1 (6)  $^{83}$  END (7)  $^{84}$  -» (b - WRONG!) (8)  $^{85}$ 

While conditions (a) and (c) are trivially satisfied, condition (b) is wrong, i.e. it is not the case that (7) True  $\land X = 0$  implies (8) Y = n - m. In fact, the two assertions are completely unrelated and it is easy to find a counterexample (say, Y = X = m = 0 and n = 1).

If we want (b) to hold, we need to strengthen the invariant so that it implies the post-condition (8). One very simple way to do this is to let the invariant be the postcondition. So let's return to our skeleton, instantiate | with Y = n - m, and check conditions (a) to (c) again. (1)  $^{86}$  -» (a - WRONG!) (2)  $^{87}$  WHILE X <> 0 DO (3)  $^{88}$  -» (c - WRONG!) (4)  $^{89}$  Y ::= Y - 1; (5)  $^{90}$  X ::= X - 1 (6)  $^{91}$  END (7)  $^{92}$  -» (b - OK) (8)  $^{93}$ 

This time, condition (b) holds trivially, but (a) and (c) are broken. Condition (a) requires that (1)  $X = m \land Y = n$  implies (2) Y = n - m. If we substitute X by m we have to show that m = n - m for arbitrary m and n, which does not hold (for instance, when m = n = 1). Condition (c) requires that n - m - 1 = n - m, which fails, for instance, for n = 1 and m = 0. So, although Y = n - m holds at the end of the loop, it does not hold from the start, and it doesn't hold on each iteration; it is not a correct invariant.

This failure is not very surprising: the variable Y changes during the loop, while m and n are constant, so the assertion we chose didn't have much chance of being an invariant!

To do better, we need to generalize (8) to some statement that is equivalent to (8) when X is 0, since this will be the case when the loop terminates, and that "fills the gap" in some appropriate way when X is nonzero. Looking at how the loop works, we can observe that X and Y are decremented together until X reaches 0. So, if X = 2 and Y = 5 initially, after one iteration of the loop we obtain X = 1 and Y = 4; after two iterations X = 0 and Y = 1

```
^{78}X=m/\Y=n
^{79} {\tt True}
^{80}True/\X<>0
81True
82True
<sup>83</sup>True
^{84}True/\X=0
85Y=n-m
^{86}X=m/\Y=n
87Y=n-m
^{88}Y=n-m/\X<>0
89Y-1=n-m
90Y = n - m
91Y=n-m
^{92}Y=n-m/\X=0
93Y=n-m
```

= 3; and then the loop stops. Notice that the difference between Y and X stays constant between iterations; initially, Y = n and X = m, so this difference is always n - m. So let's try instantiating I in the skeleton above with Y - X = n - m. (1)  $^{94}$  -» (a - OK) (2)  $^{95}$  WHILE X <> 0 DO (3)  $^{96}$  -» (c - OK) (4)  $^{97}$  Y ::= Y - 1; (5)  $^{98}$  X ::= X - 1 (6)  $^{99}$  END (7)  $^{100}$  -» (b - OK) (8)  $^{101}$ 

Success! Conditions (a), (b) and (c) all hold now. (To verify (c), we need to check that, under the assumption that  $X \neq 0$ , we have Y - X = (Y - 1) - (X - 1); this holds for all natural numbers X and Y.)

#### 21.3.2 Exercise: Slow Assignment

Exercise: 2 stars (slow\_assignment) A roundabout way of assigning a number currently stored in X to the variable Y is to start Y at 0, then decrement X until it hits 0, incrementing Y at each step. Here is a program that implements this idea:  $^{102}$  Y ::= 0; WHILE X <> 0 DO X ::= X - 1; Y ::= Y + 1; END  $^{103}$  Write an informal decorated program showing that this is correct.

#### 21.3.3 Exercise: Slow Addition

Exercise: 3 stars, optional (add\_slowly\_decoration) The following program adds the variable X into the variable Z by repeatedly decrementing X and incrementing Z. WHILE X <> 0 DO Z ::= Z + 1; X ::= X - 1 END

Following the pattern of the subtract\_slowly example above, pick a precondition and postcondition that give an appropriate specification of  $add\_slowly$ ; then (informally) decorate the program accordingly.

## 21.3.4 Example: Parity

Here is a cute little program for computing the parity of the value initially stored in X (due to Daniel Cristofani).  $^{104}$  WHILE  $2 \le X$  DO X := X - 2 END  $^{105}$  The mathematical parity

```
94X=m/\Y=n

95Y-X=n-m

96Y-X=n-m/\X<>0

97(Y-1)-(X-1)=n-m

98Y-(X-1)=n-m

99Y-X=n-m

100Y-X=n-m/\X=0

101Y=n-m

102X=m

103Y=m

104X=m

105X=paritym
```

function used in the specification is defined in Coq as follows:

The postcondition does not hold at the beginning of the loop, since  $m=parity\ m$  does not hold for an arbitrary m, so we cannot use that as an invariant. To find an invariant that works, let's think a bit about what this loop does. On each iteration it decrements X by 2, which preserves the parity of X. So the parity of X does not change, i.e. it is invariant. The initial value of X is m, so the parity of X is always equal to the parity of m. Using parity X = parity m as an invariant we obtain the following decorated program:  $^{106}$  -» (a - OK)  $^{107}$  WHILE 2 <= X DO  $^{108}$  -» (c - OK)  $^{109}$  X ::= X - 2  $^{110}$  END  $^{111}$  -» (b - OK)  $^{112}$ 

With this invariant, conditions (a), (b), and (c) are all satisfied. For verifying (b), we observe that, when X < 2, we have parity X = X (we can easily see this in the definition of parity). For verifying (c), we observe that, when  $2 \le X$ , we have parity X = parity(X-2).

Exercise: 3 stars, optional (parity\_formal) Translate this proof to Coq. Refer to the reduce-to-zero example for ideas. You may find the following two lemmas useful:

```
Lemma parity_ge_2 : \forall x,
  2 \leq x \rightarrow
  parity (x - 2) = parity x.
Proof.
  induction x; intro. reflexivity.
  destruct x. inversion H. inversion H1.
  simpl. rewrite \leftarrow \min_{n=0}^{\infty} n_n = 0. reflexivity.
Qed.
Lemma parity_lt_2: \forall x,
  \neg 2 < x \rightarrow
  parity (x) = x.
Proof.
  intros. induction x. reflexivity. destruct x. reflexivity.
     apply ex_falso_quodlibet. apply H. omega.
Qed.
 106x=m
 ^{107}parityX=paritym
 108parityX=paritym/\2<=X
 109 parity(X-2)=paritym
 ^{110}parityX=paritym
 111parityX=paritym/\X<2</pre>
 112X=paritym
```

```
Theorem parity_correct: \forall m,  
{{ fun st \Rightarrow st \ X = m }}
WHILE BLe (ANum 2) (Ald X) DO
X: = AMinus (Ald X) (ANum 2)
END
{{ fun st \Rightarrow st \ X = parity \ m }}.
Proof.
Admitted.
```

#### 21.3.5 Example: Finding Square Roots

The following program computes the square root of X by naive iteration:  $^{113}$  Z ::= 0; WHILE  $(Z+1)^*(Z+1) \le X$  DO Z ::= Z+1 END  $^{114}$ 

As above, we can try to use the postcondition as a candidate invariant, obtaining the following decorated program: (1)  $^{115}$  -» (a - second conjunct of (2) WRONG!) (2)  $^{116}$  Z ::= 0; (3)  $^{117}$  WHILE (Z+1)\*(Z+1) <= X DO (4)  $^{118}$  -» (c - WRONG!) (5)  $^{119}$  Z ::= Z+1 (6)  $^{120}$  END (7)  $^{121}$  -» (b - OK) (8)  $^{122}$ 

This didn't work very well: both conditions (a) and (c) failed. Looking at condition (c), we see that the second conjunct of (4) is almost the same as the first conjunct of (5), except that (4) mentions X while (5) mentions m. But note that X is never assigned in this program, so we should have X=m, but we didn't propagate this information from (1) into the loop invariant.

Also, looking at the second conjunct of (8), it seems quite hopeless as an invariant – and we don't even need it, since we can obtain it from the negation of the guard (third conjunct in (7)), again under the assumption that X=m.

So we now try  $X=m \land Z \times Z \le m$  as the loop invariant:  $^{123}$  -» (a - OK)  $^{124}$  Z ::= 0;  $^{125}$ 

```
\begin{array}{c} 113 \chi = m \\ 114 Z * Z < = m / m < (Z+1) * (Z+1) \\ 115 \chi = m \\ 116 0 * 0 < = m / m < 1 * 1 \\ 117 Z * Z < = m / m < (Z+1) * (Z+1) \\ 118 Z * Z < = m / (Z+1) * (Z+1) < = X \\ 119 (Z+1) * (Z+1) < = m / m < (Z+2) * (Z+2) \\ 120 Z * Z < = m / m < (Z+1) * (Z+1) \\ 121 Z * Z < = m / m < (Z+1) * (Z+1) / \chi < (Z+1) * (Z+1) \\ 122 Z * Z < = m / m < (Z+1) * (Z+1) \\ 123 \chi = m \\ 124 \chi = m / 0 * 0 < = m \\ 125 \chi = m / \chi = Z < = m \\ 125 \chi = m / \chi = Z < = m \end{array}
```

WHILE  $(Z+1)^*(Z+1) \le X$  DO  $^{126}$  -»  $(c - OK)^{127}$  Z ::=  $Z+1^{128}$  END  $^{129}$  -»  $(b - OK)^{130}$  This works, since conditions (a), (b), and (c) are now all trivially satisfied.

Very often, if a variable is used in a loop in a read-only fashion (i.e., it is referred to by the program or by the specification and it is not changed by the loop) it is necessary to add the fact that it doesn't change to the loop invariant.

#### 21.3.6 Example: Squaring

Here is a program that squares X by repeated addition:

```
^{131} Y ::= 0; Z ::= 0; WHILE Y <> X DO Z ::= Z + X; Y ::= Y + 1 END ^{132}
```

The first thing to note is that the loop reads X but doesn't change its value. As we saw in the previous example, in such cases it is a good idea to add X = m to the invariant. The other thing we often use in the invariant is the postcondition, so let's add that too, leading to the invariant candidate Z = m × m  $\wedge$  X = m. <sup>133</sup> -» (a - WRONG) <sup>134</sup> Y ::= 0; <sup>135</sup> Z ::= 0; <sup>136</sup> WHILE Y <> X DO <sup>137</sup> -» (c - WRONG) <sup>138</sup> Z ::= Z + X; <sup>139</sup> Y ::= Y + 1 <sup>140</sup> END <sup>141</sup> -» (b - OK) <sup>142</sup>

Conditions (a) and (c) fail because of the  $Z=m\times m$  part. While Z starts at 0 and works itself up to  $m\times m$ , we can't expect Z to be  $m\times m$  from the start. If we look at how Z progesses in the loop, after the 1st iteration Z=m, after the 2nd iteration  $Z=2^*m$ , and at the end  $Z=m\times m$ . Since the variable Y tracks how many times we go through the loop, we derive the new invariant candidate  $Z=Y\times m \wedge X=m$ . <sup>143</sup> -» (a - OK) <sup>144</sup> Y::=0; <sup>145</sup> Z::=0; <sup>146</sup>

```
^{126}\text{X=m/}\text{Z*Z}<=\text{m/}\text{(Z+1)*(Z+1)}<=\text{X}
^{127}X=m/\(Z+1)*(Z+1)<=m
^{128}X=m/\Z*Z<=m
^{129}X=m/\chi<=m/\chi<(Z+1)*(Z+1)
^{130}Z*Z <= m/m < (Z+1)*(Z+1)
^{131}X=m
^{132}Z=m*m
^{133}X=m
^{134}O=m*m/\X=m
^{135}\text{O=m*m}/\text{X=m}
^{136}Z=m*m/\X=m
^{137}Z=Y*m/\X=m/\Y<>X
^{138}Z+X=m*m/X=m
^{139}\text{Z=m*m}/\text{\chi=m}
^{140}Z=m*m/\X=m
^{141}\text{Z=m*m}/\text{X=m}/\text{Y=X}
^{142}Z=m*m
^{143}X=m
^{144}\text{O=O*m}/\text{X=m}
^{145}\text{O=Y*m}/\text{X=m}
^{146}Z=Y*m/\X=m
```

WHILE Y <> X DO  $^{147}$  -» (c - OK)  $^{148}$  Z ::= Z + X;  $^{149}$  Y ::= Y + 1  $^{150}$  END  $^{151}$  -» (b - OK)  $^{152}$ 

This new invariant makes the proof go through: all three conditions are easy to check.

It is worth comparing the postcondition  $Z = m \times m$  and the  $Z = Y \times m$  conjunct of the invariant. It is often the case that one has to replace auxiliary variables (parameters) with variables – or with expressions involving both variables and parameters (like m - Y) – when going from postconditions to invariants.

#### 21.3.7 Exercise: Factorial

**Exercise: 3 stars (factorial)** Recall that n! denotes the factorial of n (i.e. n! = 1\*2\*...\*n). Here is an Imp program that calculates the factorial of the number initially stored in the variable X and puts it in the variable Y:  $^{153}$ ; Y ::= 1 WHILE X <> 0 DO Y ::= Y \* X X ::= X - 1 END  $^{154}$ 

Fill in the blanks in following decorated program:  $^{155}$  -»  $^{156}$  Y ::= 1;  $^{157}$  WHILE X <> 0 DO  $^{158}$  -»  $^{159}$  Y ::= Y \* X;  $^{160}$  X ::= X - 1  $^{161}$  END  $^{162}$  -»  $^{163}$ 

#### 21.3.8 Exercise: Min

**Exercise:** 3 stars (Min\_Hoare) Fill in valid decorations for the following program. For the => steps in your annotations, you may rely (silently) on the following facts about min Lemma lemma1: forall x y, (x=0 \/ y=0) -> min x y = 0. Lemma lemma2: forall x y, min (x-1) (y-1) = (min x y) - 1.

plus, as usual, standard high-school algebra.

```
^{147}Z=Y*m/\X=m/\Y<>X
^{148}Z+X=(Y+1)*m/X=m
^{149}Z=(Y+1)*m/X=m
^{150}\text{Z=Y*m}/\text{\chi=m}
^{151}Z=Y*m/\X=m/\Y=X
^{152}Z=m*m
^{153}X=m
^{154}Y=m!
^{155}X=m
156
157
158
159
160
161
162
163 \text{ Y=m}!
```

```
^{164} -» ^{165} X ::= a; ^{166} Y ::= b; ^{167} Z ::= 0; ^{168} WHILE (X <> 0 /\ Y <> 0) DO ^{169} -» ^{170} X := X - 1; ^{171} Y := Y - 1; ^{172} Z := Z + 1; ^{173} END ^{174} -» ^{175}
```

**Exercise:** 3 stars (two\_loops) Here is a very inefficient way of adding 3 numbers: X ::= 0; Y ::= 0; Z ::= c; WHILE X <> a DO X ::= X + 1; Z ::= Z + 1 END; WHILE Y <> b DO Y ::= Y + 1; Z ::= Z + 1 END

Show that it does what it should by filling in the blanks in the following decorated program.

 $^{176}$  -»  $^{177}$  X ::= 0;  $^{178}$  Y ::= 0;  $^{179}$  Z ::= c;  $^{180}$  WHILE X <> a DO  $^{181}$  -»  $^{182}$  X ::= X + 1;  $^{183}$  Z ::= Z + 1  $^{184}$  END;  $^{185}$  -»  $^{186}$  WHILE Y <> b DO  $^{187}$  -»  $^{188}$  Y ::= Y + 1;  $^{189}$  Z ::= Z + 1  $^{190}$  END  $^{191}$  -»  $^{192}$ 

#### 21.3.9 Exercise: Power Series

**Exercise:** 4 stars, optional (dpow2\_down) Here is a program that computes the series:  $1 + 2 + 2^2 + ... + 2^m = 2^m + 1 - 1$  X ::= 0; Y ::= 1; Z ::= 1; WHILE X <> m DO Z ::= 2 \* Z; Y ::= Y + Z; X ::= X + 1; END Write a decorated program for this.

```

^{192}7 = a + b + c
```

# 21.4 Weakest Preconditions (Advanced)

Some Hoare triples are more interesting than others. For example,  $^{193}$  X ::= Y + 1  $^{194}$  is *not* very interesting: although it is perfectly valid, it tells us nothing useful. Since the precondition isn't satisfied by any state, it doesn't describe any situations where we can use the command X ::= Y + 1 to achieve the postcondition X < 5.

By contrast,  $^{195}$  X ::= Y + 1  $^{196}$  is useful: it tells us that, if we can somehow create a situation in which we know that Y  $\leq$  4  $\wedge$  Z = 0, then running this command will produce a state satisfying the postcondition. However, this triple is still not as useful as it could be, because the Z = 0 clause in the precondition actually has nothing to do with the postcondition X  $\leq$  5. The *most* useful triple (for a given command and postcondition) is this one:  $^{197}$  X ::= Y + 1  $^{198}$  In other words, Y  $\leq$  4 is the *weakest* valid precondition of the command X ::= Y + 1 for the postcondition X  $\leq$  5.

In general, we say that "P is the weakest precondition of command c for postcondition Q" if  $\{\{P\}\}\}$  c  $\{\{Q\}\}\}$  and if, whenever P' is an assertion such that  $\{\{P'\}\}\}$  c  $\{\{Q\}\}\}$ , we have P' st implies P st for all states st.

```
Definition is_wp P c Q := \{\{P\}\}\ c \{\{Q\}\}\ \land \forall P', \{\{P'\}\}\ c \{\{Q\}\}\ \rightarrow (P' -» P).
```

That is, P is the weakest precondition of c for Q if (a) P is a precondition for Q and c, and (b) P is the weakest (easiest to satisfy) assertion that guarantees Q after executing c.

Exercise: 1 star, optional (wp) What are the weakest preconditions of the following commands for the following postconditions? 1) <sup>199</sup> SKIP <sup>200</sup>

```
2) ^{201} X ::= Y + Z ^{202}
```

- 3)  $^{203}$  X ::= Y  $^{204}$
- 4)  $^{205}$  IFB X == 0 THEN Y ::= Z + 1 ELSE Y ::= W + 2 FI  $^{206}$
- 5)  $^{207}$  X ::= 5  $^{208}$

```
^{193} {\tt False}
^{194}X<=5
^{195}Y<=4/\Z=0
196X<=5
<sup>197</sup>Y<=4
<sup>198</sup>X<=5
199 7
200 X = 5
201 7
^{202}X=5
203 7
^{204}X=Y
205_{?}
206Y=5
207
208 X=0
```

```
6) <sup>209</sup> WHILE True DO X ::= 0 END <sup>210</sup> \square
```

Exercise: 3 stars, advanced, optional (is\_wp\_formal) Prove formally using the definition of hoare\_triple that  $Y \le 4$  is indeed the weakest precondition of X := Y + 1 with respect to postcondition  $X \le 5$ .

```
Theorem is_wp_example : is_wp (fun st \Rightarrow st \ Y \le 4) (X ::= APlus (Ald Y) (ANum 1)) (fun st \Rightarrow st \ X \le 5). Proof.

Admitted.
```

Exercise: 2 stars, advanced (hoare\_asgn\_weakest) Show that the precondition in the rule hoare\_asgn is in fact the weakest precondition.

```
Theorem hoare_asgn_weakest : \forall \ Q \ X \ a, is_wp (Q \ [X \ | -> a]) \ (X ::= a) \ Q. Proof.

Admitted.
```

Exercise: 2 stars, advanced, optional (hoare\_havoc\_weakest) Show that your havoc\_pre rule from the *himp\_hoare* exercise in the Hoare chapter returns the weakest precondition. Module HIMP2.

Import Himp.

```
Lemma hoare_havoc_weakest : \forall (P \ Q : \mathsf{Assertion}) \ (X : \mathsf{id}), \{\{\ P\ \}\} \ \mathsf{HAVOC} \ X \ \{\{\ Q\ \}\} \to P \ \mathsf{-} \Rightarrow \mathsf{havoc\_pre} \ X \ Q. Proof. Admitted. End \mathsf{HIMP2}.
```

# 21.5 Formal Decorated Programs (Advanced)

The informal conventions for decorated programs amount to a way of displaying Hoare triples in which commands are annotated with enough embedded assertions that checking the validity of the triple is reduced to simple logical and algebraic calculations showing that some assertions imply others. In this section, we show that this informal presentation style

<sup>&</sup>lt;sup>209</sup>? <sup>210</sup>X=0

can actually be made completely formal and indeed that checking the validity of decorated programs can mostly be automated.

## 21.5.1 Syntax

The first thing we need to do is to formalize a variant of the syntax of commands with embedded assertions. We call the new commands decorated commands, or **dcom**s.

```
Inductive dcom: Type :=
    DCSkip : Assertion \rightarrow dcom
    \mathsf{DCSeq}: \mathbf{dcom} \to \mathbf{dcom} \to \mathbf{dcom}
    DCAsgn : id \rightarrow aexp \rightarrow Assertion \rightarrow dcom
    \mathsf{DCIf}: \mathsf{bexp} \to \mathsf{Assertion} \to \mathsf{dcom} \to \mathsf{Assertion} \to \mathsf{dcom}
               \rightarrow Assertion\rightarrow dcom
    DCWhile : bexp \rightarrow Assertion \rightarrow dcom \rightarrow Assertion \rightarrow dcom
    \mathsf{DCPre}:\mathsf{Assertion}\to\mathsf{dcom}\to\mathsf{dcom}
   DCPost : dcom \rightarrow Assertion \rightarrow dcom.
Tactic Notation "dcom_cases" tactic(first) ident(c) :=
  first:
  [ Case_aux c "Skip" | Case_aux c "Seq" | Case_aux c "Asgn"
    Case_aux c "If" | Case_aux c "While"
   | Case\_aux \ c "Pre" | Case\_aux \ c "Post" |.
Notation "'SKIP' {{ P }}"
        := (\mathsf{DCSkip}\ P)
        (at level 10): dcom\_scope.
Notation "l'::=' a {{ P }}"
        := (\mathsf{DCAsgn}\ l\ a\ P)
        (at level 60, a at next level): dcom\_scope.
Notation "'WHILE' b 'DO' {{ Pbody }} d 'END' {{ Ppost }}"
        := (DCWhile \ b \ Pbody \ d \ Ppost)
        (at level 80, right associativity) : dcom\_scope.
Notation "'IFB' b 'THEN' {{ P }} d 'ELSE' {{ P' }} d' 'FI' {{ Q }}"
        := (\mathsf{DCIf}\ b\ P\ d\ P'\ d'\ Q)
        (at level 80, right associativity) : dcom\_scope.
Notation "'->>' {{ P}} d"
        := (\mathsf{DCPre}\ P\ d)
        (at level 90, right associativity): dcom\_scope.
Notation "\{\{P\}\}\ d"
        := (\mathsf{DCPre}\ P\ d)
        (at level 90): dcom\_scope.
Notation "d '->>' {{ P }}"
        := (\mathsf{DCPost}\ d\ P)
        (at level 80, right associativity): dcom\_scope.
```

```
Notation " d ;; d' " := (\mathsf{DCSeq}\ d\ d') \\ (\text{at level } 80, \, \text{right associativity}) : \ dcom\_scope. Delimit Scope dcom\_scope with dcom.
```

To avoid clashing with the existing Notation definitions for ordinary **com**mands, we introduce these notations in a special scope called *dcom\_scope*, and we wrap examples with the declaration % **dcom** to signal that we want the notations to be interpreted in this scope.

Careful readers will note that we've defined two notations for the DCPre constructor, one with and one without a -». The "without" version is intended to be used to supply the initial precondition at the very top of the program.

```
Example dec_while : dcom := (
   \{\{ \text{ fun } st \Rightarrow \mathsf{True } \}\}
   WHILE (BNot (BEq (Ald X) (ANum 0)))
  DO
      \{\{ \text{ fun } st \Rightarrow \text{True} \land st \ \mathsf{X} \neq 0 \} \}
      X ::= (AMinus (Ald X) (ANum 1))
      \{\{ \text{ fun } \bot \Rightarrow \mathsf{True } \}\}
   END
   \{\{ \text{ fun } st \Rightarrow \text{True} \land st X = 0 \}\} - 
   \{\{ \text{ fun } st \Rightarrow st \ X = 0 \} \}
) \% dcom.
    It is easy to go from a dcom to a com by erasing all annotations.
Fixpoint extract (d:\mathbf{dcom}) : \mathbf{com} :=
   match d with
     DCSkip _ \Rightarrow SKIP
     DCSeq d1 d2 \Rightarrow (\text{extract } d1 ;; \text{ extract } d2)
     \mathsf{DCAsgn}\ X\ a\ \_\Rightarrow X::=a
     DCIf b - d1 - d2 \rightarrow IFB b THEN extract d1 ELSE extract d2 FI
     DCWhile b - d \rightarrow WHILE b DO extract d END
     DCPre _{-} d \Rightarrow extract d
    DCPost d \rightarrow \text{extract } d
   end.
```

The choice of exactly where to put assertions in the definition of **dcom** is a bit subtle. The simplest thing to do would be to annotate every **dcom** with a precondition and postcondition. But this would result in very verbose programs with a lot of repeated annotations: for example, a program like SKIP;SKIP would have to be annotated as  $^{211}$  ( $^{212}$  SKIP  $^{213}$ );

 $<sup>^{211} \</sup>mathbf{P}$ 

<sup>212</sup>**p** 

<sup>213&</sup>lt;sub>p</sub>

 $(^{214}$  SKIP  $^{215})$   $^{216}$ , with pre- and post-conditions on each SKIP, plus identical pre- and post-conditions on the semicolon!

Instead, the rule we've followed is this:

- The *post*-condition expected by each **dcom** d is embedded in d
- The pre-condition is supplied by the context.

In other words, the invariant of the representation is that a **dcom** d together with a precondition P determines a Hoare triple  $\{\{P\}\}$  (extract d)  $\{\{post d\}\}$ , where post is defined as follows:

```
Fixpoint post (d:\mathbf{dcom}): Assertion := match d with | DCSkip P\Rightarrow P | DCSeq d1 d2\Rightarrow post d2 | DCAsgn X a Q\Rightarrow Q | DCIf _- _- d1 _- d2 Q\Rightarrow Q | DCWhile b Pbody c Ppost <math>\Rightarrow Ppost | DCPre _- d\Rightarrow post d | DCPost c Q\Rightarrow Q end.
```

Similarly, we can extract the "initial precondition" from a decorated program.

```
Fixpoint pre (d:\mathbf{dcom}): Assertion := match d with | DCSkip P\Rightarrow fun st\Rightarrow True | DCSeq c1 c2\Rightarrow pre c1 | DCAsgn X a Q\Rightarrow fun st\Rightarrow True | DCIf _- _- t _- e _- \Rightarrow fun st\Rightarrow True | DCWhile b Pbody c Ppost <math>\Rightarrow fun st\Rightarrow True | DCPre P c \Rightarrow P | DCPost c Q\Rightarrow pre c end.
```

This function is not doing anything sophisticated like calculating a weakest precondition; it just recursively searches for an explicit annotation at the very beginning of the program, returning default answers for programs that lack an explicit precondition (like a bare assignment or SKIP).

Using pre and post, and assuming that we adopt the convention of always supplying an explicit precondition annotation at the very beginning of our decorated programs, we can express what it means for a decorated program to be correct as follows:

```
<sup>214</sup>p
<sup>215</sup>p
<sup>216</sup>p
```

```
Definition dec_correct (d:dcom) := \{\{pre d\}\}\} (extract d) \{\{post d\}\}\}.
```

To check whether this Hoare triple is *valid*, we need a way to extract the "proof obligations" from a decorated program. These obligations are often called *verification conditions*, because they are the facts that must be verified to see that the decorations are logically consistent and thus add up to a complete proof of correctness.

## 21.5.2 Extracting Verification Conditions

The function verification\_conditions takes a **dcom** d together with a precondition P and returns a *proposition* that, if it can be proved, implies that the triple {{P}} (extract d) {{post d}} is valid.

It does this by walking over d and generating a big conjunction including all the "local checks" that we listed when we described the informal rules for decorated programs. (Strictly speaking, we need to massage the informal rules a little bit to add some uses of the rule of consequence, but the correspondence should be clear.)

```
Fixpoint verification_conditions (P : Assertion) (d: dcom) : Prop :=
   match d with
   | DCSkip Q \Rightarrow
        (P -  Q)
   | DCSeq d1 d2 \Rightarrow
        verification_conditions P d1
        \land verification_conditions (post d1) d2
   \mid \mathsf{DCAsgn}\ X\ a\ Q \Rightarrow
        (P \rightarrow Q [X \rightarrow a])
   | DCIf b P1 d1 P2 d2 Q \Rightarrow
         ((fun st \Rightarrow P \ st \land bassn \ b \ st) ->> P1)
        \land ((fun st \Rightarrow P \ st \land \neg (bassn b \ st)) -> P2)
        \land (Q «-» post d1) \land (Q «-» post d2)
        ∧ verification_conditions P1 d1
        \land verification_conditions P2 d2
   | DCWhile b Pbody d Ppost \Rightarrow
         (P - *) post d
        \land (Pbody «-» (fun st \Rightarrow post d st \land bassn b st))
        \land (Ppost «-» (fun st \Rightarrow post d st \land \text{``(bassn } b st)))
        \land verification_conditions Pbody d
   | DCPre P' d \Rightarrow
         (P - P') \wedge \text{verification\_conditions } P' d
   | DCPost d Q \Rightarrow
        verification_conditions P \ d \land (post \ d \rightarrow Q)
   end.
```

And now, the key theorem, which states that verification\_conditions does its job correctly. Not surprisingly, we need to use each of the Hoare Logic rules at some point in the proof. We have used *in* variants of several tactics before to apply them to values in the context rather than the goal. An extension of this idea is the syntax *tactic* in \*, which applies *tactic* in the goal and every hypothesis in the context. We most commonly use this facility in conjunction with the simpl tactic, as below.

```
Theorem verification_correct : \forall d P,
  verification_conditions P \ d \rightarrow \{\{P\}\}\ (\text{extract } d) \ \{\{\text{post } d\}\}.

## 21.5.3 Examples

The propositions generated by verification\_conditions are fairly big, and they contain many conjuncts that are essentially trivial.

```
Eval simpl in (verification_conditions (fun st \Rightarrow \text{True}) dec_while). 
==> (((fun _: state => True) -» (fun _: state => True)) /\ ((fun _: state => True) -» (fun _: state => True)) /\ (fun st : state => True /\ bassn (BNot (BEq (AId X) (ANum 0))) st) /\ (fun st : state => True /\ bassn (BNot (BEq (AId X) (ANum 0))) st) /\ (fun st : state => True /\ ^ bassn (BNot (BEq (AId X) (ANum 0))) st) /\ (fun st : state => True /\ bassn (BNot (BEq (AId X) (ANum 0))) st) /\ (fun st : state => True /\ bassn (BNot (BEq (AId X) (ANum 0))) st) -» (fun _: state => True) X |-> AMinus (AId X) (ANum 1)) /\ (fun st : state => True /\ ^ bassn (BNot (BEq (AId X) (ANum 0))) st) -» (fun st : state => st X = 0)
```

In principle, we could certainly work with them using just the tactics we have so far, but we can make things much smoother with a bit of automation. We first define a custom *verify* tactic that applies splitting repeatedly to turn all the conjunctions into separate subgoals and then uses omega and eauto (a handy general-purpose automation tactic that we'll discuss in detail later) to deal with as many of them as possible.

```
Lemma ble_nat_true_iff : \forall n m : nat,
  ble_nat n m = true \leftrightarrow n < m.
Proof.
  intros n m. split. apply ble_nat_true.
  generalize dependent m. induction n; intros m H. reflexivity.
    simpl. destruct m. inversion H.
    apply le_S_n in H. apply IHn. assumption.
Qed.
Lemma ble_nat_false_iff : \forall n m : nat,
  ble_nat n m = false \leftrightarrow (n < m).
Proof.
  intros n m. split. apply ble_nat_false.
  generalize dependent m. induction n; intros m H.
    apply ex_falso_quodlibet. apply H. apply le_0_n.
    simpl. destruct m. reflexivity.
    apply IHn. intro Hc. apply H. apply e_n_S. assumption.
Qed.
```

```
Tactic Notation "verify" :=
  apply verification_correct;
  repeat split;
  simpl; unfold assert_implies;
  unfold bassn in *; unfold beval in *; unfold aeval in *;
  unfold assn_sub; intros;
  repeat rewrite update_eq;
  repeat (rewrite update_neq; [| (intro X; inversion X)]);
  simpl in *;
  repeat match goal with [H: \_ \land \_ \vdash \_] \Rightarrow \text{destruct } H \text{ end};
  repeat rewrite not_true_iff_false in *;
  repeat rewrite not_false_iff_true in *;
  repeat rewrite negb_true_iff in *;
  repeat rewrite negb_false_iff in *;
  repeat rewrite beq_nat_true_iff in *;
  repeat rewrite beq_nat_false_iff in *;
  repeat rewrite ble_nat_true_iff in *;
  repeat rewrite ble_nat_false_iff in *;
  try subst;
  repeat
     match goal with
       |st: \mathsf{state} \vdash \_| \Rightarrow
          match goal with
             [H: st \_ = \_ \vdash \_] \Rightarrow \text{rewrite} \rightarrow H \text{ in }^*; \text{clear } H
          |[H:\_=st\_\vdash\_] \Rightarrow \text{rewrite} \leftarrow H \text{ in }^*; \text{clear } H
          end
     end:
  try eauto; try omega.
    What's left after verify does its thing is "just the interesting parts" of checking that
the decorations are correct. For very simple examples verify immediately solves the goal
(provided that the annotations are correct).
Theorem dec_while_correct:
  dec_correct dec_while.
Proof. verify. Qed.
    Another example (formalizing a decorated program we've seen before):
Example subtract_slowly_dec (m:nat) (p:nat) : dcom := (
     \{\{ \text{ fun } st \Rightarrow st \ X = m \land st \ Z = p \}\} \ - \infty
     \{\{ \text{ fun } st \Rightarrow st \ \mathsf{Z} - st \ \mathsf{X} = p - m \} \}
  WHILE BNot (BEq (Ald X) (ANum 0))
  DO {{ fun st \Rightarrow st \ Z - st \ X = p - m \land st \ X \neq 0 }} - »
         \{\{ \text{ fun } st \Rightarrow (st Z - 1) - (st X - 1) = p - m \} \}
```

```
Z::= AMinus (Ald Z) (ANum 1)  \{ \{ \text{ fun } st \Rightarrow st \text{ Z} - (st \text{ X} - 1) = p - m \} \} ; ; \\ \text{X::= AMinus (Ald X) (ANum 1)} \\ \{ \{ \text{ fun } st \Rightarrow st \text{ Z} - st \text{ X} = p - m \} \} \\ \text{END} \\ \{ \{ \text{ fun } st \Rightarrow st \text{ Z} - st \text{ X} = p - m \wedge st \text{ X} = 0 \} \} - \text{``} \\ \{ \{ \text{ fun } st \Rightarrow st \text{ Z} = p - m \} \} \\ ) \% \ dcom. \\ \text{Theorem subtract\_slowly\_dec\_correct: } \forall \ m \ p, \\ \text{dec\_correct (subtract\_slowly\_dec } m \ p). \\ \text{Proof. intros } m \ p. \ verify. \text{ Qed.} \\
```

Exercise: 3 stars, advanced (slow\_assignment\_dec) In the slow\_assignment exercise above, we saw a roundabout way of assigning a number currently stored in X to the variable Y: start Y at 0, then decrement X until it hits 0, incrementing Y at each step.

Write a *formal* version of this decorated program and prove it correct.

```
\label{eq:complexity} \begin{split} & \texttt{Example slow\_assignment\_dec} \ (m : \texttt{nat}) : \ \textbf{dcom} := \\ & \textit{admit}. \end{split} \label{eq:complexity} \begin{aligned} & \texttt{Theorem slow\_assignment\_dec\_correct} : \ \forall \ m, \\ & \texttt{dec\_correct} \ (\texttt{slow\_assignment\_dec} \ m). \end{aligned} \label{eq:complexity} \\ & \texttt{Proof.} \ \textit{Admitted}. \end{aligned}
```

Exercise: 4 stars, advanced (factorial\_dec) Remember the factorial function we worked with before:

```
Fixpoint real_fact (n:\mathsf{nat}): \mathsf{nat} := \mathsf{match}\ n \ \mathsf{with} \ | \ \mathsf{O} \Rightarrow 1 \ | \ \mathsf{S}\ n' \Rightarrow n \times (\mathsf{real\_fact}\ n') \ \mathsf{end}.
```

Following the pattern of subtract\_slowly\_dec, write a decorated program that implements the factorial function and prove it correct.

# Chapter 22

# Library Hoare

## 22.1 Hoare: Hoare Logic, Part I

Require Export Imp.

In the past couple of chapters, we've begun applying the mathematical tools developed in the first part of the course to studying the theory of a small programming language, Imp.

- We defined a type of abstract syntax trees for Imp, together with an evaluation relation (a partial function on states) that specifies the operational semantics of programs.

  The language we defined, though small, captures some of the key features of full-blown languages like C, C++, and Java, including the fundamental notion of mutable state and some common control structures.
- We proved a number of *metatheoretic properties* "meta" in the sense that they are properties of the language as a whole, rather than properties of particular programs in the language. These included:
  - determinism of evaluation
  - equivalence of some different ways of writing down the definitions (e.g. functional and relational definitions of arithmetic expression evaluation)
  - guaranteed termination of certain classes of programs
  - correctness (in the sense of preserving meaning) of a number of useful program transformations
  - behavioral equivalence of programs (in the Equiv chapter).

If we stopped here, we would already have something useful: a set of tools for defining and discussing programming languages and language features that are mathematically precise, flexible, and easy to work with, applied to a set of key properties. All of these properties are

things that language designers, compiler writers, and users might care about knowing. Indeed, many of them are so fundamental to our understanding of the programming languages we deal with that we might not consciously recognize them as "theorems." But properties that seem intuitively obvious can sometimes be quite subtle (in some cases, even subtly wrong!).

We'll return to the theme of metatheoretic properties of whole languages later in the course when we discuss *types* and *type soundness*. In this chapter, though, we'll turn to a different set of issues.

Our goal is to see how to carry out some simple examples of  $program\ verification$  – i.e., using the precise definition of Imp to prove formally that particular programs satisfy particular specifications of their behavior. We'll develop a reasoning system called Floyd-Hoare Logic – often shortened to just  $Hoare\ Logic$  – in which each of the syntactic constructs of Imp is equipped with a single, generic "proof rule" that can be used to reason compositionally about the correctness of programs involving this construct.

Hoare Logic originates in the 1960s, and it continues to be the subject of intensive research right up to the present day. It lies at the core of a multitude of tools that are being used in academia and industry to specify and verify real software systems.

## 22.2 Hoare Logic

Hoare Logic combines two beautiful ideas: a natural way of writing down *specifications* of programs, and a *compositional proof technique* for proving that programs are correct with respect to such specifications – where by "compositional" we mean that the structure of proofs directly mirrors the structure of the programs that they are about.

#### 22.2.1 Assertions

To talk about specifications of programs, the first thing we need is a way of making assertions about properties that hold at particular points during a program's execution – i.e., claims about the current state of the memory when program execution reaches that point. Formally, an assertion is just a family of propositions indexed by a state.

Definition Assertion := state  $\rightarrow$  Prop.

Exercise: 1 star, optional (assertions) Module EXASSERTIONS.

Paraphrase the following assertions in English.

```
Definition as1 : Assertion := fun st \Rightarrow st X = 3.

Definition as2 : Assertion := fun st \Rightarrow st X \leq st Y.

Definition as3 : Assertion := fun st \Rightarrow st X = 3 \lor st X \leq st Y.

Definition as4 : Assertion := fun st \Rightarrow st Z \times st Z \leq st X \land
```

```
\neg \ (((S \ (st \ Z)) \times (S \ (st \ Z))) \leq st \ X). Definition as5 : Assertion := fun st \Rightarrow True.
 Definition as6 : Assertion := fun st \Rightarrow False.
 End ExAssertions.
```

This way of writing assertions can be a little bit heavy, for two reasons: (1) every single assertion that we ever write is going to begin with  $fun\ st \Rightarrow$ ; and (2) this state st is the only one that we ever use to look up variables (we will never need to talk about two different memory states at the same time). For discussing examples informally, we'll adopt some simplifying conventions: we'll drop the initial  $fun\ st \Rightarrow$ , and we'll write just X to mean st X. Thus, instead of writing

```
fun st => (st Z) * (st Z) <= m /\ ^ ((S (st Z)) * (S (st Z)) <= m) we'll write just Z * Z <= m /\ ^((S Z) * (S Z) <= m).
```

Given two assertions P and Q, we say that P *implies Q*, written P ->> Q (in ASCII, P ->> Q), if, whenever P holds in some state st, Q also holds.

```
Definition assert_implies (P \ Q : \mathsf{Assertion}) : \mathsf{Prop} := \ \forall \ st, \ P \ st \to Q \ st. Notation "P -» Q" :=  (\mathsf{assert\_implies} \ P \ Q) \ (\mathsf{at} \ \mathsf{level} \ 80) : \ \mathit{hoare\_spec\_scope}.  Open Scope \mathit{hoare\_spec\_scope}.
```

We'll also have occasion to use the "iff" variant of implication between assertions:

```
Notation "P «-» Q" := (P -  Q \land Q -  P) (at level 80) : hoare\_spec\_scope.
```

## 22.2.2 Hoare Triples

Next, we need a way of making formal claims about the behavior of commands.

Since the behavior of a command is to transform one state to another, it is natural to express claims about commands in terms of assertions that are true before and after the command executes:

• "If command c is started in a state satisfying assertion P, and if c eventually terminates in some final state, then this final state will satisfy the assertion Q."

Such a claim is called a *Hoare Triple*. The property  $\mathsf{P}$  is called the *precondition* of  $\mathsf{c}$ , while Q is the *postcondition*. Formally:

```
Definition hoare_triple (P: Assertion) \ (c: \mathbf{com}) \ (Q: Assertion) : \ Prop := \forall \ st \ st', \\ c \ / \ st \ | \ | \ st' \rightarrow P \ st \rightarrow
```

```
Q st'.
```

Since we'll be working a lot with Hoare triples, it's useful to have a compact notation:  $^1$  c  $^2$ . (The traditional notation is  $\{P\}$  c  $\{Q\}$ , but single braces are already used for other things in Coq.)

```
Notation "\{\{P\}\}\ c\ \{\{Q\}\}\}" := (hoare_triple P\ c\ Q) (at level 90,\ c at next level) : hoare\_spec\_scope.
```

(The hoare\_spec\_scope annotation here tells Coq that this notation is not global but is intended to be used in particular contexts. The Open Scope tells Coq that this file is one such context.)

Exercise: 1 star, optional (triples) Paraphrase the following Hoare triples in English.

- 1)  $^{3}$  c  $^{4}$ 
  - 2) <sup>5</sup> c <sup>6</sup>
  - 3)  $^{7}$  c  $^{8}$
  - 4) 9 c 10
  - 5) <sup>11</sup> c <sup>12</sup>
  - 6) <sup>13</sup> c <sup>14</sup>

Exercise: 1 star, optional (valid\_triples) Which of the following Hoare triples are valid - i.e., the claimed relation between P, c, and Q is true? 1) <sup>15</sup> X ::= 5 <sup>16</sup>

```
2) ^{17} X ::= X + 1 ^{18}
```

3)  $^{19}$  X ::= 5; Y ::= 0  $^{20}$ 

```
1_{\mathbf{p}}
 ^2Q
 3True
 ^4X=5
 ^{5}X=m
 ^6X=m+5)
 ^{7}X \le Y
 ^8Y<=X
 <sup>9</sup>True
^{10} {\sf False}
^{11}X=m
^{12}Y=real_factm
^{14}(Z*Z) \le m/^{((SZ)*(SZ))} \le m)
^{15} {\tt True}
^{16}X=5
^{17}X=2
^{18}X=3
<sup>19</sup>True
^{20}X=5
```

```
4) ^{21} X ::= 5 ^{22} 5) ^{23} SKIP ^{24} 6) ^{25} SKIP ^{26} 7) ^{27} WHILE True DO SKIP END ^{28} 8) ^{29} WHILE X == 0 DO X ::= X + 1 END ^{30} 9) ^{31} WHILE X <> 0 DO X ::= X + 1 END ^{32}
```

(Note that we're using informal mathematical notations for expressions inside of commands, for readability, rather than their formal **aexp** and **bexp** encodings. We'll continue doing so throughout the chapter.)

To get us warmed up for what's coming, here are two simple facts about Hoare triples.

#### 22.2.3 Proof Rules

The goal of Hoare logic is to provide a *compositional* method for proving the validity of Hoare triples. That is, the structure of a program's correctness proof should mirror the structure of

```
21X=2/\X=3
22X=0
23True
24False
25False
26True
27True
28False
29X=0
30X=1
31X=1
32X=100
```

the program itself. To this end, in the sections below, we'll introduce one rule for reasoning about each of the different syntactic forms of commands in Imp – one for assignment, one for sequencing, one for conditionals, etc. – plus a couple of "structural" rules that are useful for gluing things together. We will prove programs correct using these proof rules, without ever unfolding the definition of hoare\_triple.

#### Assignment

The rule for assignment is the most fundamental of the Hoare logic proof rules. Here's how it works.

Consider this (valid) Hoare triple:  $^{33}$  X ::= Y  $^{34}$  In English: if we start out in a state where the value of Y is 1 and we assign Y to X, then we'll finish in a state where X is 1. That is, the property of being equal to 1 gets transferred from Y to X.

Similarly, in  $^{35}$  X ::= Y + Z  $^{36}$  the same property (being equal to one) gets transferred to X from the expression Y + Z on the right-hand side of the assignment.

More generally, if **a** is any arithmetic expression, then  $^{37}$  X ::= a  $^{38}$  is a valid Hoare triple. This can be made even more general. To conclude that an arbitrary property Q holds after X ::= a, we need to assume that Q holds before X ::= a, but with all occurrences of X replaced by a in Q. This leads to the Hoare rule for assignment  $^{39}$  X ::= a  $^{40}$  where "Q [X |-> a]" is pronounced "Q where a is substituted for X".

```
For example, these are valid applications of the assignment rule: ^{41} X ::= X + 1 ^{42} X ::= 3 ^{44} 45 X ::= 3 ^{46}
```

To formalize the rule, we must first formalize the idea of "substituting an expression for an Imp variable in an assertion." That is, given a proposition P, a variable X, and an arithmetic expression a, we want to derive another proposition P that is just the same as P except that, wherever P mentions X, P should instead mention a.

Since P is an arbitrary Coq proposition, we can't directly "edit" its text. Instead, we can achieve the effect we want by evaluating P in an updated state:

#### Definition assn\_sub $X \ a \ P$ : Assertion :=

```
\begin{array}{c} 33 \, Y = 1 \\ 34 \, X = 1 \\ 35 \, Y + Z = 1 \\ 36 \, X = 1 \\ 37 \, a = 1 \\ 38 \, X = 1 \\ 39 \, Q \, [X \, | \, - > a] \\ 40 \, Q \\ 41 \, (X < = 5) \, [X \, | \, - > X + 1] \, i.e. \, , X + 1 < = 5 \\ 42 \, X < = 5 \\ 43 \, (X = 3) \, [X \, | \, - > 3] \, i.e. \, , 3 = 3 \\ 44 \, X = 3 \\ 45 \, (0 < = X / \setminus X < = 5) \, [X \, | \, - > 3] \, i.e. \, , (0 < = 3 / \setminus 3 < = 5) \\ 46 \, 0 < = X / \setminus X < = 5 \\ \end{array}
```

```
\begin{array}{c} \texttt{fun} \ (st: \texttt{state}) \Rightarrow \\ P \ (\texttt{update} \ st \ X \ (\texttt{aeval} \ st \ a)). \end{array} Notation "P [ X |-> a ]" := (assn_sub X \ a \ P) (at level 10).
```

That is,  $P[X \mid -> a]$  is an assertion P' that is just like P except that, wherever P looks up the variable X in the current state, P' instead uses the value of the expression a.

To see how this works, let's calculate what happens with a couple of examples. First, suppose P' is  $(X \le 5)$   $[X \mid -> 3]$  – that is, more formally, P' is the Coq expression fun st => (fun st' => st' X <= 5) (update st X (aeval st (ANum 3))), which simplifies to fun st => (fun st' => st' X <= 5) (update st X 3) and further simplifies to fun st => ((update st X 3) X) <= 5) and by further simplification to fun st => (3 <= 5). That is, P' is the assertion that 3 is less than or equal to 5 (as expected).

For a more interesting example, suppose P' is  $(X \le 5)$  [X |-> X+1]. Formally, P' is the Coq expression fun st => (fun st' => st' X <= 5) (update st X (aeval st (APlus (AId X) (ANum 1)))), which simplifies to fun st => (((update st X (aeval st (APlus (AId X) (ANum 1))))) X) <= 5 and further simplifies to fun st => (aeval st (APlus (AId X) (ANum 1))) <= 5. That is, P' is the assertion that X+1 is at most 5.

Now we can give the precise proof rule for assignment:

```
(hoare_asgn) ^{47} X ::= a ^{48}
    We can prove formally that this rule is indeed valid.
Theorem hoare_asgn : \forall Q X a,
  \{\{Q [X \mid -> a]\}\} (X ::= a) \{\{Q\}\}.
Proof.
  unfold hoare_triple.
  intros Q X a st st' HE HQ.
  inversion HE. subst.
  unfold assn_sub in HQ. assumption. Qed.
   Here's a first formal proof using this rule.
Example assn_sub_example:
  \{\{(fun \ st \Rightarrow st \ X = 3) \ [X \mid -> ANum \ 3]\}\}
  (X ::= (ANum 3))
  \{\{\text{fun } st \Rightarrow st \ X = 3\}\}.
Proof.
  apply hoare_asgn. Qed.
Exercise: 2 stars (hoare_asgn_examples) Translate these informal Hoare triples... 1)
^{49} X := X + 1^{50}
 ^{47}Q[X|->a]
  ^{49}(X <= 5)[X | -> X + 1]
 50X < =5
```

```
2) ^{51} X ::= 3 ^{52} ...into formal statements and use hoare_asgn to prove them. \Box
```

Exercise: 2 stars (hoare\_asgn\_wrong) The assignment rule looks backward to almost everyone the first time they see it. If it still seems backward to you, it may help to think a little about alternative "forward" rules. Here is a seemingly natural one:

(hoare\_asgn\_wrong)  $^{53}$  X ::= a  $^{54}$  Give a counterexample showing that this rule is incorrect (informally). Hint: The rule universally quantifies over the arithmetic expression a, and your counterexample needs to exhibit an a for which the rule doesn't work.

Exercise: 3 stars, advanced (hoare\_asgn\_fwd) However, using an auxiliary variable m to remember the original value of X we can define a Hoare rule for assignment that does, intuitively, "work forwards" rather than backwards.

(hoare\_asgn\_fwd)  $^{55}$  X ::= a  $^{56}$  (where st' = update st X m) Note that we use the original value of X to reconstruct the state st' before the assignment took place. Prove that this rule is correct (the first hypothesis is the functional extensionality axiom, which you will need at some point). Also note that this rule is more complicated than hoare\_asgn.

```
Theorem hoare_asgn_fwd:
```

```
 (\forall \ \{X \ Y \colon \mathsf{Type}\} \ \{f \ g : X \to Y\}, \ (\forall \ (x \colon X), f \ x = g \ x) \to f = g) \to \forall \ m \ a \ Q, \\ \{\{\mathsf{fun} \ st \Rightarrow Q \ st \land st \ \mathsf{X} = m\}\} \\ \mathsf{X} : := a \\ \{\{\mathsf{fun} \ st \Rightarrow Q \ (\mathsf{update} \ st \ \mathsf{X} \ m) \land st \ \mathsf{X} = \mathsf{aeval} \ (\mathsf{update} \ st \ \mathsf{X} \ m) \ a \ \}\}. \\ \mathsf{Proof.} \\ \mathsf{intros} \ functional\_extensionality \ v \ a \ Q. \\ Admitted. \\ \square
```

#### Consequence

Sometimes the preconditions and postconditions we get from the Hoare rules won't quite be the ones we want in the particular situation at hand – they may be logically equivalent but have a different syntactic form that fails to unify with the goal we are trying to prove,

```
51 (0<=X/\X<=5) [X|->3]

52 0<=X/\X<=5

53 True

54 X=a

55 funst=>Qst/\stX=m

56 funst=>Qst'/\stX=aevalst'a
```

or they actually may be logically weaker (for preconditions) or stronger (for postconditions) than what we need.

For instance, while  $^{57}$  X ::= 3  $^{58}$ , follows directly from the assignment rule,  $^{59}$  X ::= 3  $^{60}$ . does not. This triple is valid, but it is not an instance of hoare\_asgn because True and (X = 3) [X |-> 3] are not syntactically equal assertions. However, they are logically equivalent, so if one triple is valid, then the other must certainly be as well. We might capture this observation with the following rule:  $^{61}$  c  $^{62}$  P - P'

(hoare\_consequence\_pre\_equiv)  $^{63}$  c  $^{64}$  Taking this line of thought a bit further, we can see that strengthening the precondition or weakening the postcondition of a valid triple always produces another valid triple. This observation is captured by two *Rules of Consequence*.  $^{65}$  c  $^{66}$  P -» P'

```
(hoare_consequence_pre) ^{67} c ^{68}
    <sup>69</sup> c <sup>70</sup> Q' -» Q
 (hoare_consequence_post) ^{71} c ^{72}
    Here are the formal versions:
Theorem hoare_consequence_pre : \forall (P P' Q : Assertion) c,
   \{\{P'\}\}\ c\ \{\{Q\}\}\ \rightarrow
   P 	o P' 	o
   \{\{P\}\}\ c\ \{\{Q\}\}.
Proof.
   intros P P' Q c Hhoare Himp.
   intros st st' Hc HP. apply (Hhoare st st').
   assumption. apply Himp. assumption. Qed.
Theorem hoare_consequence_post : \forall (P \ Q \ Q' : Assertion) \ c,
   \{\{P\}\}\ c\ \{\{Q'\}\}\} \rightarrow
  57(X=3)[X|->3]
  58X=3
  ^{59} {\tt True}
  ^{60}X=3
  61<sub>p</sub>,
  62<sub>0</sub>
  63P
  64<sub>0</sub>
  65p;
  66<sub>Q</sub>
  67_{\mbox{P}}
  68<sub>Q</sub>

#### Digression: The eapply Tactic

This is a good moment to introduce another convenient feature of Coq. We had to write "with (P' := ...)" explicitly in the proof of hoare\_asgn\_example1 and hoare\_consequence above, to make sure that all of the metavariables in the premises to the hoare\_consequence\_pre rule would be set to specific values. (Since P' doesn't appear in the conclusion of hoare\_consequence\_pre, the process of unifying the conclusion with the current goal doesn't constrain P' to a specific assertion.)

This is a little annoying, both because the assertion is a bit long and also because for hoare\_asgn\_example1 the very next thing we are going to do – applying the hoare\_asgn rule – will tell us exactly what it should be! We can use eapply instead of apply to tell Coq, essentially, "Be patient: The missing part is going to be filled in soon."

```
Example hoare_asgn_example1': \{\{\text{fun } st \Rightarrow \text{True}\}\}\} (X ::= (ANum 1)) \{\{\text{fun } st \Rightarrow st \ X = 1\}\}. Proof. eapply hoare_consequence_pre. apply hoare_asgn. intros st \ H. reflexivity. Qed.
```

In general, eapply H tactic works just like apply H except that, instead of failing if unifying the goal with the conclusion of H does not determine how to instantiate all of the variables appearing in the premises of H, eapply H will replace these variables with so-called existential variables (written ?nnn) as placeholders for expressions that will be determined (by further unification) later in the proof.

In order for Qed to succeed, all existential variables need to be determined by the end of the proof. Otherwise Coq will (rightly) refuse to accept the proof. Remember that the Coq tactics build proof objects, and proof objects containing existential variables are not complete.

```
\begin{array}{l} \text{Lemma silly1}: \ \forall \ (P: \mathbf{nat} \to \mathbf{nat} \to \mathtt{Prop}) \ (Q: \mathbf{nat} \to \mathtt{Prop}), \\ (\forall \ x \ y: \mathbf{nat}, \ P \ x \ y) \to \\ (\forall \ x \ y: \mathbf{nat}, \ P \ x \ y \to Q \ x) \to \\ Q \ 42. \\ \\ \text{Proof.} \\ \text{intros} \ P \ Q \ HP \ HQ. \ \texttt{eapply} \ HQ. \ \texttt{apply} \ HP. \end{array}
```

Coq gives a warning after apply HP: No more subgoals but non-instantiated existential variables: Existential  $1 = ?171 : P : \mathbf{nat} \to \mathbf{nat} \to \mathsf{Prop}\ Q : \mathbf{nat} \to \mathsf{Prop}\ HP : \forall \, \mathsf{x}\,\,\mathsf{y} : \mathbf{nat}, P \, \mathsf{x}\,\,\mathsf{y} \to Q \,\,\mathsf{x} \vdash \mathbf{nat}$ 

(dependent evars: ?171 open,)

You can use Grab Existential Variables. Trying to finish the proof with Qed gives an error:

Error: Attempt to save a proof with existential variables still

#### Abort.

An additional constraint is that existential variables cannot be instantiated with terms containing (ordinary) variables that did not exist at the time the existential variable was created.

```
Lemma silly2 :
```

```
\begin{array}{l} \forall\;(P:\mathsf{nat}\to\mathsf{nat}\to\mathsf{Prop})\;(Q:\mathsf{nat}\to\mathsf{Prop}),\\ (\exists\;y\,,\;P\;42\;y)\to\\ (\forall\;x\;y:\mathsf{nat},\;P\;x\;y\to Q\;x)\to\\ Q\;42. \end{array}
```

Proof.

intros  $P \ Q \ HP \ HQ$ . eapply HQ. destruct HP as  $[y \ HP']$ .

Doing apply HP' above fails with the following error: Error: Impossible to unify "?175" with "y". In this case there is an easy fix: doing destruct HP before doing eapply HQ.

Abort.

```
Lemma silly2_fixed:
```

```
\begin{array}{l} \forall \; (P: \mathsf{nat} \to \mathsf{nat} \to \mathsf{Prop}) \; (Q: \mathsf{nat} \to \mathsf{Prop}), \\ (\exists \; y , \; P \; 42 \; y) \to \\ (\forall \; x \; y : \mathsf{nat}, \; P \; x \; y \to Q \; x) \to \\ Q \; 42. \end{array}
```

Proof.

intros P Q HP HQ. destruct HP as [y HP']. eapply HQ. apply HP'.

Qed.

In the last step we did apply HP' which unifies the existential variable in the goal with the variable y. The assumption tactic doesn't work in this case, since it cannot handle existential variables. However, Coq also provides an eassumption tactic that solves the goal if one of the premises matches the goal up to instantiations of existential variables. We can use it instead of apply HP'.

```
 \begin{array}{l} \texttt{Lemma silly2\_eassumption}: \ \forall \ (P: \textbf{nat} \rightarrow \textbf{nat} \rightarrow \texttt{Prop}) \ (Q: \textbf{nat} \rightarrow \texttt{Prop}), \\ (\exists \ y \text{, } P \ 42 \ y) \rightarrow \\ (\forall \ x \ y : \textbf{nat}, \ P \ x \ y \rightarrow Q \ x) \rightarrow \\ Q \ 42. \end{array}
```

Proof.

intros  $P \ Q \ HP \ HQ$ . destruct HP as  $[y \ HP']$ . eapply HQ. eassumption. Qed.

Exercise: 2 stars (hoare\_asgn\_examples\_2) Translate these informal Hoare triples...  $^{80}$  X ::= X + 1  $^{81}$   $^{82}$  X ::= 3  $^{83}$  ...into formal statements and use hoare\_asgn and hoare\_consequence\_pre to prove them.

### Skip

Since SKIP doesn't change the state, it preserves any property P:

```
\begin{array}{l} \text{(hoare\_skip)} \ ^{84} \ \text{SKIP} \ ^{85} \\ \\ \text{Theorem hoare\_skip} : \ \forall \ P, \\ \\ \{P\} \} \ \text{SKIP} \ \{\{P\} \}. \\ \\ \text{Proof.} \\ \\ \text{intros} \ P \ st \ st' \ H \ HP. \ \text{inversion} \ H. \ \text{subst.} \\ \\ \text{assumption.} \ \text{Qed.} \end{array}
```

#### Sequencing

More interestingly, if the command c1 takes any state where P holds to a state where Q holds, and if c2 takes any state where Q holds to one where R holds, then doing c1 followed by c2 will take any state where P holds to one where R holds:  $^{86}$  c1  $^{87}$   $^{88}$  c2  $^{89}$ 

```
(hoare_seq) 90 c1;;c2 91
Theorem hoare_seq : \forall P Q R c1 c2,
       \{\{Q\}\}\ c2\ \{\{R\}\}\ \rightarrow
       \{\{P\}\}\ c1\ \{\{Q\}\}\ \rightarrow
       \{\{P\}\}\ c1;;c2\ \{\{R\}\}\}.
Proof.
   intros P Q R c1 c2 H1 H2 st st' H12 Pre.
   inversion H12; subst.
   apply (H1 \ st'0 \ st'); try assumption.
   apply (H2 \ st \ st'0); assumption. Qed.
  <sup>80</sup>X+1<=5
  ^{81}X<=5
  820<=3/\3<=5
  830 <= X/X <= 5
  85p
  86<sub>P</sub>
  87<mark>Q</mark>
  880
  ^{89}R
  90p
  ^{91}{\rm R}
```

Note that, in the formal rule hoare\_seq, the premises are given in "backwards" order (c2 before c1). This matches the natural flow of information in many of the situations where we'll use the rule: the natural way to construct a Hoare-logic proof is to begin at the end of the program (with the final postcondition) and push postconditions backwards through commands until we reach the beginning.

Informally, a nice way of recording a proof using the sequencing rule is as a "decorated program" where the intermediate assertion Q is written between c1 and c2:  $^{92}$  X ::= a;;  $^{93}$  <—- decoration for Q SKIP  $^{94}$ 

```
Example hoare_asgn_example3 : \forall a \ n, \{\{\text{fun } st \Rightarrow \text{aeval } st \ a = n\}\}\ (\mathsf{X}:=a;; \mathsf{SKIP}) \{\{\text{fun } st \Rightarrow st \ \mathsf{X} = n\}\}. Proof.

intros a \ n. eapply hoare_seq.

Case \ "right \ part \ of \ seq".

apply hoare_skip.

Case \ "left \ part \ of \ seq".

eapply hoare_consequence_pre. apply hoare_asgn. intros st \ H. subst. reflexivity. Qed.
```

You will most often use hoare\_seq and hoare\_consequence\_pre in conjunction with the eapply tactic, as done above.

```
Exercise: 2 stars (hoare_asgn_example4) Translate this "decorated program" into a formal proof: ^{95} -» ^{96} X ::= 1;; ^{97} -» ^{98} Y ::= 2 ^{99} Example hoare_asgn_example4 : {{fun st \Rightarrow \text{True}}} (X ::= (ANum 1);; Y ::= (ANum 2)) {{fun st \Rightarrow st \text{ X} = 1 \land st \text{ Y} = 2}}. Proof. Admitted.
```

Exercise: 3 stars (swap\_exercise) Write an Imp program c that swaps the values of X and Y and show (in Coq) that it satisfies the following specification: <sup>100</sup> c <sup>101</sup>

```
92 a=n
93 X=n
94 X=n
95 True
96 1=1
97 X=1
98 X=1/\2=2
99 X=1/\Y=2
100 X<=Y
101 Y<=X
```

```
Definition swap_program : \mathbf{com} := admit.

Theorem swap_exercise : \{\{\text{fun } st \Rightarrow st \ \mathsf{X} \leq st \ \mathsf{Y}\}\} swap_program \{\{\text{fun } st \Rightarrow st \ \mathsf{Y} \leq st \ \mathsf{X}\}\}.

Proof.

Admitted.
```

**Exercise: 3 stars (hoarestate1)** Explain why the following proposition can't be proven: forall (a : aexp) (n : nat),  $^{102}$  (X ::= (ANum 3);; Y ::= a)  $^{103}$ .

#### Conditionals

What sort of rule do we want for reasoning about conditional commands? Certainly, if the same assertion Q holds after executing either branch, then it holds after the whole conditional. So we might be tempted to write:  $^{104}$  c1  $^{105}$   $^{106}$  c2  $^{107}$ 

 $^{108}$  IFB b THEN c1 ELSE c2  $^{109}$  However, this is rather weak. For example, using this rule, we cannot show that:  $^{110}$  IFB X == 0 THEN Y ::= 2 ELSE Y ::= X + 1 FI  $^{111}$  since the rule tells us nothing about the state in which the assignments take place in the "then" and "else" branches.

But we can actually say something more precise. In the "then" branch, we know that the boolean expression b evaluates to true, and in the "else" branch, we know it evaluates to false. Making this information available in the premises of the rule gives us more information to work with when reasoning about the behavior of c1 and c2 (i.e., the reasons why they establish the postcondition Q).

```
^{112} c1 ^{113} ^{114} c2 ^{115}
```

```
102funst=>aevalsta=n
103funst=>stY=n
104p
105Q
106p
107Q
108P
109Q
110True
111X<=Y
112p/\b
113Q
114p/\~b
115Q
```

```
(hoare_if) ^{116} IFB b THEN c1 ELSE c2 FI ^{117}
```

To interpret this rule formally, we need to do a little work. Strictly speaking, the assertion we've written,  $P \wedge b$ , is the conjunction of an assertion and a boolean expression – i.e., it doesn't typecheck. To fix this, we need a way of formally "lifting" any bexp b to an assertion. We'll write bassn b for the assertion "the boolean expression b evaluates to true (in the given state)."

```
Definition bassn b: Assertion :=
   fun st \Rightarrow (beval st b = true).
    A couple of useful facts about bassn:
Lemma bexp_eval_true : \forall b st,
   beval st b = true \rightarrow (bassn b) st.
Proof.
   intros b st Hbe.
   unfold bassn. assumption. Qed.
Lemma bexp_eval_false : \forall b st,
   beval st b = false \rightarrow \neg ((bassn b) st).
Proof.
   intros b st Hbe contra.
  unfold bassn in contra.
   rewrite \rightarrow contra in Hbe. inversion Hbe. Qed.
    Now we can formalize the Hoare proof rule for conditionals and prove it correct.
Theorem hoare_if: \forall P \ Q \ b \ c1 \ c2,
   \{\{\text{fun } st \Rightarrow P \ st \land \text{bassn } b \ st\}\}\ c1\ \{\{Q\}\}\} \rightarrow
   \{\{\text{fun } st \Rightarrow P \ st \land \text{``(bassn } b \ st)\}\}\ c2\ \{\{Q\}\}\ \rightarrow
   \{\{P\}\}\ (IFB b THEN c1 ELSE c2 FI) \{\{Q\}\}.
Proof.
   intros P Q b c1 c2 HTrue HFalse st st' HE HP.
   inversion HE; subst.
   Case "b is true".
     apply (HTrue\ st\ st').
        assumption.
        split. assumption.
                  apply bexp_eval_true. assumption.
   Case "b is false".
     apply (HFalse\ st\ st').
        assumption.
        split. assumption.
 116<sub>D</sub>
 117<sub>0</sub>
```

apply bexp\_eval\_false. assumption. Qed.

Here is a formal proof that the program we used to motivate the rule satisfies the specification we gave.

```
Example if_example:
     \{\{\text{fun } st \Rightarrow \mathsf{True}\}\}
  IFB (BEq (Ald X) (ANum 0))
     THEN (Y ::= (ANum 2))
     ELSE (Y := APlus (Ald X) (ANum 1))
  FΙ
     \{\{\text{fun } st \Rightarrow st \ \mathsf{X} \leq st \ \mathsf{Y}\}\}.
Proof.
  apply hoare_if.
  Case "Then".
     eapply hoare_consequence_pre. apply hoare_asgn.
     unfold bassn, assn_sub, update, assert_implies.
     simpl. intros st [ H ].
     apply beq_nat_true in H.
     rewrite H. omega.
  Case "Else".
     eapply hoare_consequence_pre. apply hoare_asgn.
     unfold assn_sub, update, assert_implies.
     simpl; intros st _. omega.
Qed.
Exercise: 2 stars (if_minus_plus) Prove the following hoare triple using hoare_if:
Theorem if_minus_plus:
  \{\{\text{fun } st \Rightarrow \mathsf{True}\}\}
  IFB (BLe (Ald X) (Ald Y))
     THEN (Z := AMinus (Ald Y) (Ald X))
     ELSE (Y := APlus (Ald X) (Ald Z))
  FΙ
  \{\{\text{fun } st \Rightarrow st \ Y = st \ X + st \ Z\}\}.
Proof.
    Admitted.
```

#### Exercise: One-sided conditionals

**Exercise:** 4 stars (if1\_hoare) In this exercise we consider extending Imp with "one-sided conditionals" of the form *IF1* b *THEN* c *FI*. Here b is a boolean expression, and c is a command. If b evaluates to true, then command c is evaluated. If b evaluates to false, then *IF1* b *THEN* c *FI* does nothing.

We recommend that you do this exercise before the ones that follow, as it should help solidify your understanding of the material.

The first step is to extend the syntax of commands and introduce the usual notations. (We've done this for you. We use a separate module to prevent polluting the global name space.)

```
Module IF1.
```

```
Inductive com : Type :=
    CSkip : com
    CAss : id \rightarrow aexp \rightarrow com
    \mathsf{CSeq} : \mathsf{com} \to \mathsf{com} \to \mathsf{com}
    Clf : bexp \rightarrow com \rightarrow com \rightarrow com
    CWhile : \mathbf{bexp} \rightarrow \mathbf{com} \rightarrow \mathbf{com}
    \mathsf{Clf1}: \mathsf{bexp} \to \mathsf{com} \to \mathsf{com}.
Tactic Notation "com_cases" tactic(first) ident(c) :=
   first;
   [Case\_aux\ c\ "SKIP"\ |\ Case\_aux\ c\ "::="\ |\ Case\_aux\ c\ ";"
   | Case_aux c "IFB" | Case_aux c "WHILE" | Case_aux c "CIF1" ].
Notation "'SKIP'" :=
   CSkip.
Notation "c1;; c2" :=
   (CSeq c1 c2) (at level 80, right associativity).
Notation "X '::=' a" :=
   (CAss X a) (at level 60).
Notation "'WHILE' b 'DO' c 'END'" :=
   (CWhile b c) (at level 80, right associativity).
Notation "'IFB' e1 'THEN' e2 'ELSE' e3 'FI'" :=
   (Clf e1 e2 e3) (at level 80, right associativity).
Notation "'IF1' b 'THEN' c 'FI'" :=
   (Clf1 b c) (at level 80, right associativity).
    Next we need to extend the evaluation relation to accommodate IF1 branches. This is
for you to do... What rule(s) need to be added to ceval to evaluate one-sided conditionals?
Reserved Notation "c1'/' st'||' st'" (at level 40, st at level 39).
Inductive ceval: com \rightarrow state \rightarrow state \rightarrow Prop :=
    \mathsf{E\_Skip}: \forall \ st: \mathsf{state}, \ \mathsf{SKIP} \ / \ st \mid \mid \ st
   \mid \mathsf{E}_{-}\mathsf{Ass} : \forall \ (st : \mathsf{state}) \ (a1 : \mathsf{aexp}) \ (n : \mathsf{nat}) \ (X : \mathsf{id}),
                  aeval st a1 = n \rightarrow (X := a1) / st \mid | update st X n
   \mid \mathsf{E}_{\mathsf{Seq}} : \forall \ (c1 \ c2 : \mathsf{com}) \ (st \ st' \ st'' : \mathsf{state}),
                  c1 / st \mid \mid st' \rightarrow c2 / st' \mid \mid st'' \rightarrow (c1 ;; c2) / st \mid \mid st''
   \mid \mathsf{E}_{\mathsf{-}}\mathsf{lfTrue} : \forall (st \ st' : \mathsf{state}) \ (b1 : \mathsf{bexp}) \ (c1 \ c2 : \mathsf{com}),
                      beval st b1 = true \rightarrow
```

 $c1 / st \mid \mid st' \rightarrow (IFB \ b1 \ THEN \ c1 \ ELSE \ c2 \ FI) / st \mid \mid st'$ 

```
| E_{-}lfFalse : \forall (st st' : state) (b1 : bexp) (c1 c2 : com),
                      beval st b1 = false \rightarrow
                      c2 / st \mid \mid st' \rightarrow (\text{IFB } b1 \text{ THEN } c1 \text{ ELSE } c2 \text{ FI}) / st \mid \mid st'
  \mid \mathsf{E}_{-}\mathsf{WhileEnd} : \forall (b1 : \mathsf{bexp}) (st : \mathsf{state}) (c1 : \mathsf{com}),
                       beval st b1 = false \rightarrow (WHILE b1 DO c1 END) / st | | st
  | E_WhileLoop : \forall (st st' st'' : state) (b1 : bexp) (c1 : com),
                         beval st b1 = true \rightarrow
                         c1 / st \mid \mid st' \rightarrow
                         (WHILE b1 DO c1 END) / st' | | st'' \rightarrow
                         (WHILE b1 DO c1 END) / st \mid \mid st"
  where "c1 '/' st '||' st'" := (ceval c1 st st').
Tactic Notation "ceval_cases" tactic(first) ident(c) :=
  [ Case_aux c "E_Skip" | Case_aux c "E_Ass" | Case_aux c "E_Seq"
    Case_aux c "E_IfTrue" | Case_aux c "E_IfFalse"
   | Case_aux c "E_WhileEnd" | Case_aux c "E_WhileLoop"
  ].
   Now we repeat (verbatim) the definition and notation of Hoare triples.
Definition hoare_triple (P:Assertion) (c:com) (Q:Assertion) : Prop :=
  \forall st st',
         c / st \mid \mid st' \rightarrow
         P \ st \rightarrow
          Q st'.
Notation "\{\{P\}\}\ c \{\{Q\}\}\}" := (hoare_triple P \ c \ Q)
                                               (at level 90, c at next level)
                                               : hoare_spec_scope.
```

Finally, we (i.e., you) need to state and prove a theorem, *hoare\_if1*, that expresses an appropriate Hoare logic proof rule for one-sided conditionals. Try to come up with a rule that is both sound and as precise as possible.

For full credit, prove formally that your rule is precise enough to show the following valid Hoare triple:  $^{118}$  IF1 Y <> 0 THEN X ::= X + Y FI  $^{119}$ 

Hint: Your proof of this triple may need to use the other proof rules also. Because we're working in a separate module, you'll need to copy here the rules you find necessary.

```
Lemma hoare_if1_good:
```

```
\{\{ \text{ fun } st \Rightarrow st \text{ X + } st \text{ Y = } st \text{ Z } \}\}
```

<sup>118</sup> X+Y=Z

 $<sup>^{119}</sup>$ X=Z

```
IF1 BNot (BEq (Ald Y) (ANum 0)) THEN X ::= APlus (Ald X) (Ald Y)
FI
\{\{ \text{ fun } st \Rightarrow st \ X = st \ Z \ \}\}.
Proof. Admitted.
End IF1.
```

#### Loops

Finally, we need a rule for reasoning about while loops.

Suppose we have a loop WHILE b DO c END and we want to find a pre-condition P and a post-condition Q such that <sup>120</sup> WHILE b DO c END <sup>121</sup> is a valid triple.

First of all, let's think about the case where b is false at the beginning – i.e., let's assume that the loop body never executes at all. In this case, the loop behaves like SKIP, so we might be tempted to write  $^{122}$  WHILE b DO c END  $^{123}$ . But, as we remarked above for the conditional, we know a little more at the end – not just P, but also the fact that b is false in the current state. So we can enrich the postcondition a little:  $^{124}$  WHILE b DO c END  $^{125}$  What about the case where the loop body does get executed? In order to ensure that P holds when the loop finally exits, we certainly need to make sure that the command c guarantees that P holds whenever c is finished. Moreover, since P holds at the beginning of the first execution of c, and since each execution of c re-establishes P when it finishes, we can always assume that P holds at the beginning of c. This leads us to the following rule:  $^{126}$  c  $^{127}$ 

#### <sup>128</sup> WHILE b DO c END <sup>129</sup>

This is almost the rule we want, but again it can be improved a little: at the beginning of the loop body, we know not only that P holds, but also that the guard b is true in the current state. This gives us a little more information to use in reasoning about c (showing that it establishes the invariant by the time it finishes). This gives us the final version of the rule:  $^{130}$  c  $^{131}$ 

(hoare\_while)  $^{132}$  WHILE b DO c END  $^{133}$  The proposition P is called an *invariant* of the loop.

One subtlety in the terminology is that calling some assertion P a "loop invariant" doesn't just mean that it is preserved by the body of the loop in question (i.e.,  $\{\{P\}\}\}$  c  $\{\{P\}\}\}$ , where c is the loop body), but rather that P together with the fact that the loop's guard is true is a sufficient precondition for c to ensure P as a postcondition.

This is a slightly (but significantly) weaker requirement. For example, if P is the assertion X = 0, then P is an invariant of the loop WHILE X = 2 DO X := 1 END although it is clearly not preserved by the body of the loop.

```
Lemma hoare_while : \forall P \ b \ c,
  \{\{\text{fun } st \Rightarrow P \ st \ \land \ \text{bassn} \ b \ st\}\} \ c \ \{\{P\}\} \rightarrow
  \{\{P\}\}\ WHILE b DO c END \{\{\text{fun } st \Rightarrow P \ st \land \neg \text{ (bassn } b \ st)\}\}.
Proof.
  intros P b c Hhoare st st' He HP.
  remember (WHILE b DO c END) as wcom\ eqn:Hegwcom.
  ceval_cases (induction He) Case;
     try (inversion Hegwcom); subst; clear Hegwcom.
  Case "E_WhileEnd".
     split. assumption. apply bexp_eval_false. assumption.
  Case "E_WhileLoop".

 <sup>133</sup>P/\~b
```

```
apply ble\_nat\_false in Heqle. omega. Qed.
```

We can use the while rule to prove the following Hoare triple, which may seem surprising at first...

```
Theorem always_loop_hoare: \forall P \ Q, \{\{P\}\} WHILE BTrue DO SKIP END \{\{Q\}\}\}. Proof.

intros P \ Q.

apply hoare_consequence_pre with (P' := \text{fun } st : \text{state} \Rightarrow \text{True}).

eapply hoare_consequence_post.

apply hoare_while.

Case "Loop body preserves invariant".

apply hoare_post_true. intros st. apply |.

Case "Loop invariant and negated guard imply postcondition".

simpl. intros st \ [Hinv \ Hguard].

apply ex_falso_quodlibet. apply Hguard. reflexivity.

Case "Precondition implies invariant".

intros st \ H. constructor. Qed.
```

Of course, this result is not surprising if we remember that the definition of hoare\_triple asserts that the postcondition must hold *only* when the command terminates. If the command doesn't terminate, we can prove anything we like about the post-condition.

Hoare rules that only talk about terminating commands are often said to describe a logic of "partial" correctness. It is also possible to give Hoare rules for "total" correctness, which build in the fact that the commands terminate. However, in this course we will only talk about partial correctness.

#### Exercise: REPEAT

Module REPEATEXERCISE.

Exercise: 4 stars, advanced (hoare\_repeat) In this exercise, we'll add a new command to our language of commands: *REPEAT* c *UNTIL* a *END*. You will write the evaluation rule for repeat and add a new Hoare rule to the language for programs involving it.

```
\begin{array}{l} \textbf{Inductive com} : \texttt{Type} := \\ | \ \mathsf{CSkip} : \mathbf{com} \\ | \ \mathsf{CAsgn} : \mathbf{id} \to \mathbf{aexp} \to \mathbf{com} \\ | \ \mathsf{CSeq} : \mathbf{com} \to \mathbf{com} \to \mathbf{com} \\ | \ \mathsf{CIf} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com} \to \mathbf{com} \\ | \ \mathsf{CWhile} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com} \\ | \ \mathsf{CRepeat} : \ \mathbf{com} \to \mathbf{bexp} \to \mathbf{com}. \end{array}
```

REPEAT behaves like WHILE, except that the loop guard is checked after each execution of the body, with the loop repeating as long as the guard stays false. Because of this, the body will always execute at least once.

```
Tactic Notation "com_cases" tactic(first) ident(c) :=
   Case\_aux \ c "SKIP" | Case\_aux \ c "::=" | Case\_aux \ c ";"
   Case_aux c "IFB" | Case_aux c "WHILE"
  | Case\_aux \ c "CRepeat" |.
Notation "'SKIP'" :=
  CSkip.
Notation "c1;; c2" :=
  (CSeq c1 c2) (at level 80, right associativity).
Notation "X '::=' a" :=
  (CAsgn X a) (at level 60).
Notation "'WHILE' b 'DO' c 'END'" :=
  (CWhile b c) (at level 80, right associativity).
Notation "'IFB' e1 'THEN' e2 'ELSE' e3 'FI'" :=
  (Clf e1 e2 e3) (at level 80, right associativity).
Notation "'REPEAT' e1 'UNTIL' b2 'END'" :=
  (CRepeat e1 b2) (at level 80, right associativity).
```

Add new rules for *REPEAT* to **ceval** below. You can use the rules for *WHILE* as a guide, but remember that the body of a *REPEAT* should always execute at least once, and that the loop ends when the guard becomes true. Then update the *ceval\_cases* tactic to handle these added cases.

```
Inductive ceval : state \rightarrow com \rightarrow state \rightarrow Prop :=
   \mid \mathsf{E}_{\mathsf{S}}\mathsf{kip} : \forall st,
          ceval st SKIP st
   \mid \mathsf{E}_{-}\mathsf{Ass} : \forall \ st \ a1 \ n \ X,
           aeval st a1 = n \rightarrow
           ceval st (X ::= a1) (update st X n)
   \mid \mathsf{E\_Seq} : \forall \ c1 \ c2 \ st \ st' \ st'',
          ceval st c1 st' \rightarrow
           ceval st' c2 st'' \rightarrow
           ceval st (c1;; c2) st"
   \mid \mathsf{E\_IfTrue} : \forall st st' b1 c1 c2,
          beval st b1 = true \rightarrow
          ceval st c1 st' \rightarrow
           ceval st (IFB b1 THEN c1 ELSE c2 FI) st'
   \mid \mathsf{E}_{\mathsf{-}}\mathsf{IfFalse} : \forall st st' b1 c1 c2,
           beval st b1 = false \rightarrow
          ceval st \ c2 \ st' \rightarrow
```

```
ceval st (IFB b1 THEN c1 ELSE c2 FI) st'
  \mid E_{\text{-}}WhileEnd: \forall b1 \ st \ c1,
       beval st b1 = false \rightarrow
       ceval st (WHILE b1 DO c1 END) st
  \mid \mathsf{E}_{-}\mathsf{WhileLoop} : \forall st \ st' \ st'' \ b1 \ c1,
       beval st b1 = true \rightarrow
       ceval st c1 st' \rightarrow
       ceval st' (WHILE b1 DO c1 END) st'' \rightarrow
       ceval st (WHILE b1 DO c1 END) st''
Tactic Notation "ceval_cases" tactic(first) ident(c) :=
  first;
  [ Case\_aux \ c "E_Skip" | Case\_aux \ c "E_Ass"
    Case_aux c "E_Seq"
   Case_aux c "E_IfTrue" | Case_aux c "E_IfFalse"
   | Case\_aux\ c "E_WhileEnd" | Case\_aux\ c "E_WhileLoop"
].
    A couple of definitions from above, copied here so they use the new ceval.
Notation "c1 '/' st '||' st'" := (ceval st \ c1 \ st')
                                         (at level 40, st at level 39).
Definition hoare_triple (P:Assertion) (c:com) (Q:Assertion)
                              : Prop :=
  \forall st st', (c / st \mid \mid st') \rightarrow P st \rightarrow Q st'.
Notation "\{\{P\}\}\ c \{\{Q\}\}\}" :=
  (hoare_triple P c Q) (at level 90, c at next level).
    To make sure you've got the evaluation rules for REPEAT right, prove that ex1_repeat
evaluates correctly.
Definition ex1_repeat :=
  REPEAT
     X ::= ANum 1;;
     Y ::= APlus (Ald Y) (ANum 1)
  UNTIL (BEq (Ald X) (ANum 1)) END.
Theorem ex1_repeat_works:
  ex1_repeat / empty_state ||
                   update (update empty_state X 1) Y 1.
Proof.
    Admitted.
```

Now state and prove a theorem, *hoare\_repeat*, that expresses an appropriate proof rule

for repeat commands. Use hoare\_while as a model, and try to make your rule as precise as possible.

For full credit, make sure (informally) that your rule can be used to prove the following valid Hoare triple:  $^{134}$  REPEAT Y ::= X; X ::= X - 1 UNTIL X = 0 END  $^{135}$  End Repeatexercise.

#### 22.2.4 Exercise: HAVOC

**Exercise:** 3 stars (himp\_hoare) In this exercise, we will derive proof rules for the *HAVOC* command which we studied in the last chapter. First, we enclose this work in a separate module, and recall the syntax and big-step semantics of Himp commands.

Module HIMP.

```
Inductive com : Type :=
    CSkip : com
    CAsgn: id \rightarrow aexp \rightarrow com
    \mathsf{CSeq}: \mathsf{com} \to \mathsf{com} \to \mathsf{com}
    \mathsf{Clf} : \mathsf{bexp} \to \mathsf{com} \to \mathsf{com} \to \mathsf{com}
    CWhile : bexp \rightarrow com \rightarrow com
   \mid CHavoc : \mathsf{id} 	o \mathsf{com}.
Tactic Notation "com_cases" tactic(first) ident(c) :=
  first:
  [Case\_aux\ c\ "SKIP"\ |\ Case\_aux\ c\ "::="\ |\ Case\_aux\ c\ ";"
  | Case_aux c "IFB" | Case_aux c "WHILE" | Case_aux c "HAVOC" ].
Notation "'SKIP'" :=
  CSkip.
Notation "X '::=' a" :=
  (CAsgn X a) (at level 60).
Notation "c1;; c2" :=
  (CSeq c1 c2) (at level 80, right associativity).
Notation "'WHILE' b 'DO' c 'END'" :=
  (CWhile b c) (at level 80, right associativity).
Notation "'IFB' e1 'THEN' e2 'ELSE' e3 'FI'" :=
  (Clf e1 e2 e3) (at level 80, right associativity).
Notation "'HAVOC' X" := (CHavoc X) (at level 60).
Reserved Notation "c1',' st'||' st'" (at level 40, st at level 39).
Inductive ceval: com \rightarrow state \rightarrow state \rightarrow Prop :=
  \mid \mathsf{E\_Skip} : \forall \ st : \mathsf{state}, \ \mathsf{SKIP} \ / \ st \mid \mid \ st
134X>0
 ^{135}X=0/Y>0
```

```
\mid \mathsf{E}_{-}\mathsf{Ass} : \forall \ (st : \mathsf{state}) \ (a1 : \mathsf{aexp}) \ (n : \mathsf{nat}) \ (X : \mathsf{id}),
                    aeval st a1 = n \rightarrow (X ::= a1) / st || update st X n
   \mid \mathsf{E\_Seq} : \forall \ (c1 \ c2 : \mathsf{com}) \ (st \ st' \ st'' : \mathsf{state}),
                    c1 / st \mid \mid st' \rightarrow c2 / st' \mid \mid st'' \rightarrow (c1;; c2) / st \mid \mid st''
   | E_{-}IfTrue : \forall (st st' : state) (b1 : bexp) (c1 c2 : com),
                         beval st b1 = true \rightarrow
                         c1 / st \mid \mid st' \rightarrow (\text{IFB } b1 \text{ THEN } c1 \text{ ELSE } c2 \text{ FI}) / st \mid \mid st'
   \mid \mathsf{E}_{\mathsf{-}}\mathsf{lfFalse} : \forall \ (st \ st' : \mathsf{state}) \ (b1 : \mathsf{bexp}) \ (c1 \ c2 : \mathsf{com}),
                           beval st b1 = false \rightarrow
                           c2 / st \mid \mid st' \rightarrow (\text{IFB } b1 \text{ THEN } c1 \text{ ELSE } c2 \text{ FI}) / st \mid \mid st'
   \mid \mathsf{E}_{-}\mathsf{WhileEnd} : \forall \ (b1 : \mathsf{bexp}) \ (st : \mathsf{state}) \ (c1 : \mathsf{com}),
                             beval st b1 = false \rightarrow (WHILE b1 DO c1 END) / st || st
   | E_WhileLoop : \forall (st st' st'' : state) (b1 : bexp) (c1 : com),
                              beval st b1 = true \rightarrow
                              c1 / st \mid \mid st' \rightarrow
                              (WHILE b1 DO c1 END) / st' \mid \mid st'' \rightarrow
                              (WHILE b1 DO c1 END) / st \mid \mid st"
   \mid \mathsf{E}_{-}\mathsf{Havoc} : \forall \ (st : \mathsf{state}) \ (X : \mathsf{id}) \ (n : \mathsf{nat}),
                        (HAVOC X) / st || update st X n
   where "c1 '/' st '||' st'" := (ceval c1 \ st \ st').
Tactic Notation "ceval_cases" tactic(first) ident(c) :=
   first;
     Case_aux c "E_Skip" | Case_aux c "E_Ass" | Case_aux c "E_Seq"
     Case_aux c "E_IfTrue" | Case_aux c "E_IfFalse"
     Case_aux c "E_WhileEnd" | Case_aux c "E_WhileLoop"
     Case\_aux \ c \ "E\_Havoc" ].
```

The definition of Hoare triples is exactly as before. Unlike our notion of program equivalence, which had subtle consequences with occassionally nonterminating commands (exercise  $havoc\_diverge$ ), this definition is still fully satisfactory. Convince yourself of this before proceeding.

```
Definition hoare_triple (P: Assertion) (c: com) (Q: Assertion) : Prop := \forall st \ st', \ c \ / \ st \ | \ | \ st' \to P \ st \to Q \ st'.
Notation "{{ P}} c {{ Q}}" := (hoare_triple P \ c \ Q) (at level 90, \ c \ at \ next \ level) : <math>hoare\_spec\_scope.
```

Complete the Hoare rule for *HAVOC* commands below by defining havoc\_pre and prove that the resulting rule is correct.

```
\label{eq:definition} {\tt Definition\ havoc\_pre} \ (X: {\sf id}) \ (Q: {\tt Assertion}): \ {\tt Assertion} := \\ {\tt admit}.
```

Theorem hoare\_havoc :  $\forall (Q : Assertion) (X : id)$ ,

#### 22.2.5 Review

Above, we've introduced Hoare Logic as a tool to reasoning about Imp programs. In the reminder of this chapter we will explore a systematic way to use Hoare Logic to prove properties about programs. The rules of Hoare Logic are the following:

```
(hoare_asgn) ^{136} X::=a ^{137}
(hoare_skip) ^{138} SKIP ^{139}
    <sup>140</sup> c1 <sup>141</sup> <sup>142</sup> c2 <sup>143</sup>
(hoare_seq) ^{144} c1;;c2 ^{145}
     <sup>146</sup> c1 <sup>147</sup> <sup>148</sup> c2 <sup>149</sup>
(hoare_if) ^{150} IFB b THEN c1 ELSE c2 FI ^{151}
    ^{152} c ^{153}
(hoare_while) ^{154} WHILE b DO c END ^{155}
136Q[X|->a]
^{137}Q
138<sub>P</sub>
139<sub>p</sub>
140_{\mbox{\cl}P}
141 Q
142 Q
^{143}R
144<sub>p</sub>
^{145}\mathrm{R}
^{146}\mathrm{P/b}
147<sub>Q</sub>
<sup>148</sup>P/\~b
149<sub>Q</sub>
^{150}\mathbf{P}
151<sub>0</sub>
^{152}P/\b
153<sub>p</sub>
154_{
m p}
<sup>155</sup>P/\~b
```

 $^{156}$  c  $^{157}$  P -» P' Q' -» Q

(hoare\_consequence)  $^{158}$  c  $^{159}$  In the next chapter, we'll see how these rules are used to prove that programs satisfy specifications of their behavior.

# Chapter 23

# Library Equiv

## 23.1 Equiv: Program Equivalence

Require Export Imp.

#### Some general advice for working on exercises:

- Most of the Coq proofs we ask you to do are similar to proofs that we've provided. Before starting to work on the homework problems, take the time to work through our proofs (both informally, on paper, and in Coq) and make sure you understand them in detail. This will save you a lot of time.
- The Coq proofs we're doing now are sufficiently complicated that it is more or less impossible to complete them simply by random experimentation or "following your nose." You need to start with an idea about why the property is true and how the proof is going to go. The best way to do this is to write out at least a sketch of an informal proof on paper one that intuitively convinces you of the truth of the theorem before starting to work on the formal one. Alternately, grab a friend and try to convince them that the theorem is true; then try to formalize your explanation.
- Use automation to save work! Some of the proofs in this chapter's exercises are pretty long if you try to write out all the cases explicitly.

## 23.2 Behavioral Equivalence

In the last chapter, we investigated the correctness of a very simple program transformation: the optimize\_Oplus function. The programming language we were considering was the first version of the language of arithmetic expressions – with no variables – so in that setting it was very easy to define what it *means* for a program transformation to be correct: it should always yield a program that evaluates to the same number as the original.

To go further and talk about the correctness of program transformations in the full Imp language, we need to consider the role of variables and state.

#### 23.2.1 Definitions

For **aexp**s and **bexp**s with variables, the definition we want is clear. We say that two **aexp**s or **bexp**s are *behaviorally equivalent* if they evaluate to the same result *in every state*.

```
Definition aequiv (a1 \ a2 : \mathbf{aexp}) : \mathsf{Prop} := \forall \ (st : \mathsf{state}), aeval st \ a1 = \mathsf{aeval} \ st \ a2.
Definition bequiv (b1 \ b2 : \mathbf{bexp}) : \mathsf{Prop} := \forall \ (st : \mathsf{state}), beval st \ b1 = \mathsf{beval} \ st \ b2.
```

For commands, the situation is a little more subtle. We can't simply say "two commands are behaviorally equivalent if they evaluate to the same ending state whenever they are started in the same initial state," because some commands (in some starting states) don't terminate in any final state at all! What we need instead is this: two commands are behaviorally equivalent if, for any given starting state, they either both diverge or both terminate in the same final state. A compact way to express this is "if the first one terminates in a particular state then so does the second, and vice versa."

```
Definition cequiv (c1 \ c2 : \mathbf{com}) : \mathsf{Prop} := \forall \ (st \ st' : \mathsf{state}), \ (c1 \ / \ st \ || \ st') \leftrightarrow (c2 \ / \ st \ || \ st').
```

**Exercise: 2 stars (equiv\_classes)** Given the following programs, group together those that are equivalent in Imp. For example, if you think programs (a) through (h) are all equivalent to each other, but not to (i), your answer should look like this: {a,b,c,d,e,f,g,h} {i}.

```
(a) WHILE X > 0 DO X := X + 1 END
```

- (b) IFB X = 0 THEN X := X + 1; Y := 1 ELSE Y := 0 FI; X := X Y; Y := 0
- (c) SKIP
- (d) WHILE X <> 0 DO X ::= X \* Y + 1 END
- (e) Y := 0
- (f) Y := X + 1;; WHILE X <> Y DO Y := X + 1 END
- (g) WHILE TRUE DO SKIP END
- (h) WHILE  $X \ll X$  DO X := X + 1 END
- (i) WHILE  $X \ll Y$  DO X ::= Y + 1 END

## 23.2.2 Examples

Here are some simple examples of equivalences of arithmetic and boolean expressions.

```
Theorem aequiv_example:
  aequiv (AMinus (Ald X) (Ald X)) (ANum 0).
Proof.
  intros st. simpl. omega.
Qed.
Theorem bequiv_example:
  beguiv (BEg (AMinus (Ald X) (Ald X)) (ANum 0)) BTrue.
Proof.
  intros st. unfold beval.
  rewrite aequiv_example. reflexivity.
Qed.
   For examples of command equivalence, let's start by looking at some trivial program
transformations involving SKIP:
Theorem skip_left: \forall c,
  cequiv
     (SKIP; c)
     c.
Proof.
  intros c st st'.
  split; intros H.
  Case "->".
    inversion H. subst.
    inversion H2. subst.
    assumption.
  Case "<-".
    apply E_Seq with st.
    apply E_Skip.
    assumption.
Qed.
Exercise: 2 stars (skip_right) Prove that adding a SKIP after a command results in
an equivalent program
Theorem skip_right: \forall c,
  cequiv
    (c;; SKIP)
    c.
Proof.
   Admitted.
   Similarly, here is a simple transformations that simplifies IFB commands:
Theorem IFB_true_simple: \forall c1 c2,
```

```
cequiv  \begin{array}{c} \text{(IFB BTrue THEN } c1 \text{ ELSE } c2 \text{ FI}) \\ c1. \\ \text{Proof.} \\ \text{intros } c1 \text{ } c2. \\ \text{split; intros } H. \\ Case \text{ "->".} \\ \text{inversion } H; \text{ subst. assumption. inversion } H5. \\ Case \text{ "<-".} \\ \text{apply E_IfTrue. reflexivity. assumption. Qed.} \\ \end{array}
```

Of course, few programmers would be tempted to write a conditional whose guard is literally BTrue. A more interesting case is when the guard is *equivalent* to true:

Theorem: If b is equivalent to BTrue, then IFB b THEN c1 ELSE c2 FI is equivalent to c1.

*Proof*:

• ( $\rightarrow$ ) We must show, for all st and st', that if IFB b THEN c1 ELSE c2 FI / st || st' then c1 / st || st'.

Proceed by cases on the rules that could possibly have been used to show IFB b THEN c1 ELSE c2 FI / st || st', namely  $\mathsf{E\_IfTrue}$  and  $\mathsf{E\_IfFalse}$ .

- Suppose the final rule rule in the derivation of IFB b THEN c1 ELSE c2 FI / st || st' was E\_lfTrue. We then have, by the premises of E\_lfTrue, that c1 / st || st'. This is exactly what we set out to prove.
- On the other hand, suppose the final rule in the derivation of *IFB* b *THEN* c1 *ELSE* c2 *FI* / st || st' was E\_lfFalse. We then know that beval st b = false and c2 / st || st'.

Recall that b is equivalent to BTrue, i.e. forall st, beval st b = beval st BTrue. In particular, this means that beval st b = true, since beval st BTrue = true. But this is a contradiction, since E\_IfFalse requires that beval st b = false. Thus, the final rule could not have been E\_IfFalse.

• ( $\leftarrow$ ) We must show, for all st and st', that if c1 / st || st' then IFB b THEN c1 ELSE c2 FI / st || st'.

Since b is equivalent to BTrue, we know that beval st b = beval st BTrue = true. Together with the assumption that c1 / st || st', we can apply E\_IfTrue to derive IFB b THEN c1 ELSE c2 FI / st || st'.  $\square$ 

Here is the formal version of this proof:

```
Theorem IFB_true: \forall \ b \ c1 \ c2, bequiv b BTrue \rightarrow cequiv
```

```
(IFB b THEN c1 ELSE c2 FI)
       c1.
Proof.
  intros b c1 c2 Hb.
  split; intros H.
  Case "->".
    inversion H; subst.
    SCase "b evaluates to true".
      assumption.
    SCase "b evaluates to false (contradiction)".
      rewrite Hb in H5.
      inversion H5.
  Case "<-".
    apply E_lfTrue; try assumption.
    rewrite Hb. reflexivity. Qed.
Exercise: 2 stars (IFB_false) Theorem IFB_false: \forall b \ c1 \ c2,
  bequiv b BFalse \rightarrow
  cequiv
    (IFB b THEN c1 ELSE c2 FI)
    c2.
Proof.
   Admitted.
Exercise: 3 stars (swap_if_branches) Show that we can swap the branches of an IF
by negating its condition
Theorem swap_if_branches: \forall b \ e1 \ e2,
  cequiv
    (IFB b THEN e1 ELSE e2 FI)
    (IFB BNot b THEN e2 ELSE e1 FI).
Proof.
   Admitted.
   For WHILE loops, we can give a similar pair of theorems. A loop whose guard is
equivalent to BFalse is equivalent to SKIP, while a loop whose guard is equivalent to BTrue
is equivalent to WHILE BTrue DO SKIP END (or any other non-terminating program).
The first of these facts is easy.
Theorem WHILE_false : \forall b c,
     bequiv b BFalse \rightarrow
     cequiv
        (WHILE b DO c END)
```

```
SKIP.

Proof.
intros b c Hb. split; intros H.
Case "->".
inversion H; subst.
SCase "E_WhileEnd".
apply E_Skip.
SCase "E_WhileLoop".
rewrite Hb in H2. inversion H2.
```

Case "<-". inversion H; subst.

apply  $E_-$ WhileEnd. rewrite Hb.

reflexivity. Qed.

Exercise: 2 stars, advanced, optional (WHILE\_false\_informal) Write an informal proof of WHILE\_false.

To prove the second fact, we need an auxiliary lemma stating that WHILE loops whose guards are equivalent to BTrue never terminate:

*Lemma*: If b is equivalent to BTrue, then it cannot be the case that (WHILE b DO c END) / st || st'.

*Proof*: Suppose that  $(WHILE \ b \ DO \ c \ END) \ / \ st \ || \ st'$ . We show, by induction on a derivation of  $(WHILE \ b \ DO \ c \ END) \ / \ st \ || \ st'$ , that this assumption leads to a contradiction.

- Suppose (WHILE b DO c END) / st || st' is proved using rule E\_WhileEnd. Then by assumption beval st b = false. But this contradicts the assumption that b is equivalent to BTrue.
- Suppose (WHILE b DO c END) /  $st \parallel st'$  is proved using rule E\_WhileLoop. Then we are given the induction hypothesis that (WHILE b DO c END) /  $st \parallel st'$  is contradictory, which is exactly what we are trying to prove!
- Since these are the only rules that could have been used to prove (WHILE b DO c END) /  $st \mid\mid st'$ , the other cases of the induction are immediately contradictory.  $\square$

### 23.2.3 The Functional Equivalence Axiom

Finally, let's look at simple equivalences involving assignments. For example, we might expect to be able to show that X := Ald X is equivalent to SKIP. However, when we try to show it, we get stuck in an interesting way.

```
Theorem identity_assignment_first_try : \forall (X:id), cequiv (X ::= Ald X) SKIP.

Proof.

intros. split; intro H.

Case "->".

inversion H; subst. simpl.

replace (update st X (st X)) with st.

constructor.

Abort.
```

Here we're stuck. The goal looks reasonable, but in fact it is not provable! If we look back at the set of lemmas we proved about update in the last chapter, we can see that lemma update\_same almost does the job, but not quite: it says that the original and updated states agree at all values, but this is not the same thing as saying that they are = in Coq's sense!

What is going on here? Recall that our states are just functions from identifiers to values. For Coq, functions are only equal when their definitions are syntactically the same, modulo simplification. (This is the only way we can legally apply the refl\_equal constructor of the inductively defined proposition eq!) In practice, for functions built up by repeated uses of the update operation, this means that two functions can be proven equal only if they were constructed using the same update operations, applied in the same order. In the theorem above, the sequence of updates on the first parameter cequiv is one longer than for the second parameter, so it is no wonder that the equality doesn't hold.

This problem is actually quite general. If we try to prove other simple facts, such as cequiv (X ::= X + 1); X ::= X + 1 (X ::= X + 2) or cequiv (X ::= 1); (X ::= 1)

we'll get stuck in the same way: we'll have two functions that behave the same way on all inputs, but cannot be proven to be **eq** to each other.

The reasoning principle we would like to use in these situations is called functional extensionality: for all x, f x = g x

f = g Although this principle is not derivable in Coq's built-in logic, it is safe to add it as an additional axiom.

```
Axiom functional_extensionality : \forall \{X \ Y : \mathtt{Type}\} \{f \ g : X \to Y\}, (\forall (x: X), f \ x = g \ x) \to f = g.
```

It can be shown that adding this axiom doesn't introduce any inconsistencies into Coq. (In this way, it is similar to adding one of the classical logic axioms, such as excluded\_middle.) With the benefit of this axiom we can prove our theorem.

```
Theorem identity_assignment : \forall (X:id),
  cequiv
    (X ::= \mathsf{Ald}\ X)
    SKIP.
Proof.

## 23.3 Properties of Behavioral Equivalence

We now turn to developing some of the properties of the program equivalences we have defined.

### 23.3.1 Behavioral Equivalence is an Equivalence

First, we verify that the equivalences on *aexps*, *bexps*, and **com**s really are *equivalences* – i.e., that they are reflexive, symmetric, and transitive. The proofs are all easy.

```
Lemma refl_aequiv : \forall (a : \mathbf{aexp}), aequiv a \ a.
Proof.
  intros a st. reflexivity. Qed.
Lemma sym_aequiv : \forall (a1 \ a2 : aexp),
  aequiv a1 a2 \rightarrow aequiv a2 a1.
Proof.
  intros a1 a2 H. intros st. symmetry. apply H. Qed.
Lemma trans_aequiv : \forall (a1 \ a2 \ a3 : \mathbf{aexp}),
  aequiv a1 a2 \rightarrow aequiv a2 a3 \rightarrow aequiv a1 a3.
Proof.
  unfold aequiv. intros a1 a2 a3 H12 H23 st.
  rewrite (H12 \ st). rewrite (H23 \ st). reflexivity. Qed.
Lemma refl_bequiv : \forall (b : \mathbf{bexp}), bequiv b \ b.
Proof.
  unfold bequiv. intros b st. reflexivity. Qed.
Lemma sym_bequiv : \forall (b1 \ b2 : \mathbf{bexp}),
  beguiv b1 b2 \rightarrow \text{beguiv } b2 b1.
Proof.
  unfold bequiv. intros b1 b2 H. intros st. symmetry. apply H. Qed.
Lemma trans_bequiv : \forall (b1 \ b2 \ b3 : \mathbf{bexp}),
  beguiv b1 b2 \rightarrow \text{beguiv } b2 b3 \rightarrow \text{beguiv } b1 b3.
Proof.
  unfold bequiv. intros b1 b2 b3 H12 H23 st.
  rewrite (H12 \ st). rewrite (H23 \ st). reflexivity. Qed.
Lemma refl_cequiv : \forall (c : com), cequiv c c.
Proof.
  unfold cequiv. intros c st st. apply iff_refl. Qed.
Lemma sym_cequiv : \forall (c1 c2 : com),
  cequiv c1 c2 \rightarrow cequiv c2 c1.
Proof.
  unfold cequiv. intros c1 c2 H st st'.
  assert (c1 / st \mid \mid st' \leftrightarrow c2 / st \mid \mid st') as H'.
     SCase "Proof of assertion". apply H.
  apply iff_sym. assumption.
Qed.
Lemma iff_trans : \forall (P1 \ P2 \ P3 : Prop),
```

```
\begin{array}{l} (P1 \leftrightarrow P2) \rightarrow (P2 \leftrightarrow P3) \rightarrow (P1 \leftrightarrow P3). \\ \text{Proof.} \\ \text{intros } P1 \ P2 \ P3 \ H12 \ H23. \\ \text{inversion } H12. \ \text{inversion } H23. \\ \text{split; intros } A. \\ \text{apply } H1. \ \text{apply } H. \ \text{apply } A. \\ \text{apply } H0. \ \text{apply } H2. \ \text{apply } A. \ \text{Qed.} \\ \\ \text{Lemma trans\_cequiv: } \forall \ (c1 \ c2 \ c3 : \mathbf{com}), \\ \text{cequiv } c1 \ c2 \rightarrow \text{cequiv } c2 \ c3 \rightarrow \text{cequiv } c1 \ c3. \\ \\ \text{Proof.} \\ \text{unfold cequiv. intros } c1 \ c2 \ c3 \ H12 \ H23 \ st \ st'. \\ \text{apply iff\_trans with } (c2 \ / \ st \ | \ st'). \ \text{apply } H23. \ \text{Qed.} \\ \end{array}
```

### 23.3.2 Behavioral Equivalence is a Congruence

Less obviously, behavioral equivalence is also a *congruence*. That is, the equivalence of two subprograms implies the equivalence of the larger programs in which they are embedded: aequiv a1 a1'

```
cequiv (i ::= a1) (i ::= a1')
cequiv c1 c1' cequiv c2 c2'
```

```
cequiv (c1;;c2) (c1';;c2') ...and so on.
```

(Note that we are using the inference rule notation here not as part of a definition, but simply to write down some valid implications in a readable format. We prove these implications below.)

We will see a concrete example of why these congruence properties are important in the following section (in the proof of fold\_constants\_com\_sound), but the main idea is that they allow us to replace a small part of a large program with an equivalent small part and know that the whole large programs are equivalent *without* doing an explicit proof about the non-varying parts – i.e., the "proof burden" of a small change to a large program is proportional to the size of the change, not the program.

```
Theorem CAss_congruence : \forall i \ a1 \ a1', aequiv a1 \ a1' \rightarrow cequiv (CAss i \ a1) (CAss i \ a1'). Proof.

intros i \ a1 \ a2 \ Heqv \ st \ st'. split; intros Hceval.

Case \ "-> ".

inversion Hceval. subst. apply E_Ass. rewrite Heqv. reflexivity.

Case \ "<-".
```

```
inversion Hceval. subst. apply E_Ass. rewrite Heqv. reflexivity. Qed.
```

The congruence property for loops is a little more interesting, since it requires induction. Theorem: Equivalence is a congruence for WHILE – that is, if b1 is equivalent to b1' and c1 is equivalent to c1', then WHILE b1 DO c1 END is equivalent to WHILE b1' DO c1' END.

*Proof*: Suppose b1 is equivalent to b1' and c1 is equivalent to c1'. We must show, for every st and st', that WHILE b1 DO c1 END / st || st' iff WHILE b1' DO c1' END / st || st'. We consider the two directions separately.

- (→) We show that WHILE b1 DO c1 END / st || st' implies WHILE b1' DO c1' END / st || st', by induction on a derivation of WHILE b1 DO c1 END / st || st'. The only nontrivial cases are when the final rule in the derivation is E\_WhileEnd or E\_WhileLoop.
  - E\_WhileEnd: In this case, the form of the rule gives us beval st b1 = false and st = st'. But then, since b1 and b1' are equivalent, we have beval st b1' = false, and E-WhileEnd applies, giving us WHILE b1' DO c1' END / st || st', as required.
  - E\_WhileLoop: The form of the rule now gives us beval st b1 = true, with c1 / st || st'0 and WHILE b1 DO c1 END / st'0 || st' for some state st'0, with the induction hypothesis WHILE b1' DO c1' END / st'0 || st'. Since c1 and c1' are equivalent, we know that c1' / st || st'0. And since b1 and b1' are equivalent, we have beval st b1' = true. Now E-WhileLoop applies, giving us WHILE b1' DO c1' END / st || st', as required.
- $(\leftarrow)$  Similar.  $\square$

```
Theorem CWhile_congruence : \forall \ b1 \ b1' \ c1 \ c1', bequiv b1 \ b1' \rightarrow \text{cequiv} \ c1 \ c1' \rightarrow \text{cequiv} \ (\text{WHILE} \ b1 \ \text{DO} \ c1 \ \text{END}) \ (\text{WHILE} \ b1' \ \text{DO} \ c1' \ \text{END}). Proof.

unfold bequiv,cequiv.
intros b1 \ b1' \ c1 \ c1' \ Hb1e \ Hc1e \ st \ st'.
split; intros Hce.
Case \text{"->"}.
remember \ (\text{WHILE} \ b1 \ \text{DO} \ c1 \ \text{END}) \ \text{as} \ cwhile \ eqn: Heqcwhile}.

      apply CAss_congruence. unfold aequiv. simpl.
        symmetry. apply minus_diag.
      apply refl_cequiv.
Qed.
```

# 23.4 Case Study: Constant Folding

A program transformation is a function that takes a program as input and produces some variant of the program as its output. Compiler optimizations such as constant folding are a canonical example, but there are many others.

## 23.4.1 Soundness of Program Transformations

A program transformation is *sound* if it preserves the behavior of the original program. We can define a notion of soundness for translations of **aexps**, **bexps**, and **coms**.

```
Definition atrans_sound (atrans: aexp \rightarrow aexp): Prop := \forall (a: aexp), aequiv a (atrans a).
Definition btrans_sound (btrans: bexp \rightarrow bexp): Prop := \forall (b: bexp), bequiv b (btrans b).
Definition ctrans_sound (ctrans: com \rightarrow com): Prop := \forall (c: com), cequiv c (ctrans c).
```

## 23.4.2 The Constant-Folding Transformation

An expression is *constant* when it contains no variable references.

Constant folding is an optimization that finds constant expressions and replaces them by their values.

```
Fixpoint fold_constants_aexp (a : aexp) : aexp :=
  match a with
   ANum n \Rightarrow ANum n
   Ald i \Rightarrow Ald i
   APlus a1 \ a2 \Rightarrow
       match (fold_constants_aexp a1, fold_constants_aexp a2) with
       (ANum n1, ANum n2) \Rightarrow ANum (n1 + n2)
       (a1', a2') \Rightarrow APlus a1' a2'
       end
  | AMinus a1 \ a2 \Rightarrow
       match (fold_constants_aexp a1, fold_constants_aexp a2) with
       (ANum n1, ANum n2) \Rightarrow ANum (n1 - n2)
       (a1', a2') \Rightarrow AMinus a1' a2'
       end
  | AMult a1 a2 \Rightarrow
       match (fold_constants_aexp a1, fold_constants_aexp a2) with
       (ANum n1, ANum n2) \Rightarrow ANum (n1 \times n2)
       (a1', a2') \Rightarrow \mathsf{AMult} \ a1' \ a2'
       end
  end.
Example fold_aexp_ex1 :
    fold_constants_aexp
       (AMult (APlus (ANum 1) (ANum 2)) (Ald X))
  = AMult (ANum 3) (Ald X).
Proof. reflexivity. Qed.
   Note that this version of constant folding doesn't eliminate trivial additions, etc. – we
are focusing attention on a single optimization for the sake of simplicity. It is not hard to
incorporate other ways of simplifying expressions; the definitions and proofs just get longer.
Example fold_aexp_ex2 :
    fold_constants_aexp
       (AMinus (Ald X) (APlus (AMult (ANum 0) (ANum 6)) (Ald Y)))
  = AMinus (Ald X) (APlus (ANum 0) (Ald Y)).
Proof. reflexivity. Qed.
```

Not only can we lift fold\_constants\_aexp to bexps (in the BEq and BLe cases), we can also find constant *boolean* expressions and reduce them in-place.

```
Fixpoint fold_constants_bexp (b: \mathbf{bexp}): \mathbf{bexp} := match b with | BTrue \Rightarrow BTrue | BFalse \Rightarrow BFalse
```

```
| BEq a1 a2 \Rightarrow
       match (fold_constants_aexp a1, fold_constants_aexp a2) with
       (ANum n1, ANum n2) \Rightarrow if beq_nat n1 n2 then BTrue else BFalse
       (a1', a2') \Rightarrow BEq a1' a2'
       end
  | BLe a1 a2 \Rightarrow
       match (fold_constants_aexp a1, fold_constants_aexp a2) with
       (ANum n1, ANum n2) \Rightarrow if ble_nat n1 n2 then BTrue else BFalse
       (a1', a2') \Rightarrow BLe a1' a2'
       end
  | BNot b1 \Rightarrow
       match (fold_constants_bexp b1) with
       \mid BTrue \Rightarrow BFalse
        BFalse \Rightarrow BTrue
       |b1' \Rightarrow BNot b1'
       end
  | BAnd b1 b2 \Rightarrow
       match (fold_constants_bexp b1, fold_constants_bexp b2) with
       | (BTrue, BTrue) \Rightarrow BTrue
       | (BTrue, BFalse) \Rightarrow BFalse
       | (BFalse, BTrue) \Rightarrow BFalse
       | (BFalse, BFalse) \Rightarrow BFalse
       (b1', b2') \Rightarrow \mathsf{BAnd}\ b1'\ b2'
       end
  end.
Example fold_bexp_ex1 :
    fold_constants_bexp (BAnd BTrue (BNot (BAnd BFalse BTrue)))
  = BTrue.
Proof. reflexivity. Qed.
Example fold_bexp_ex2 :
    fold_constants_bexp
       (BAnd (BEq (Ald X) (Ald Y))
               (BEq (ANum 0)
                     (AMinus (ANum 2) (APlus (ANum 1) (ANum 1)))))
  = BAnd (BEq (Ald X) (Ald Y)) BTrue.
Proof. reflexivity. Qed.
   To fold constants in a command, we apply the appropriate folding functions on all em-
bedded expressions.
Fixpoint fold_constants_com (c : com) : com :=
  match c with
  \mid SKIP \Rightarrow
```

```
SKIP
  | i ::= a \Rightarrow
       CAss i (fold_constants_aexp a)
  |c1;;c2\Rightarrow
       (fold_constants_com c1);; (fold_constants_com c2)
  | IFB b THEN c1 ELSE c2 FI \Rightarrow
       match fold_constants_bexp b with
        BTrue \Rightarrow fold\_constants\_com c1
        BFalse \Rightarrow fold_constants_com c2
       |b' \Rightarrow \text{IFB } b' \text{ THEN fold\_constants\_com } c1
                         ELSE fold_constants_com c2 FI
       end
  \mid WHILE b DO c END \Rightarrow
       match fold_constants_bexp b with
        BTrue ⇒ WHILE BTrue DO SKIP END
        BFalse \Rightarrow SKIP
       \mid b' \Rightarrow \text{WHILE } b' \text{ DO (fold\_constants\_com } c) \text{ END}
       end
  end.
Example fold_com_ex1:
  fold_constants_com
     (X ::= APlus (ANum 4) (ANum 5);;
     Y ::= AMinus (Ald X) (ANum 3);;
      IFB BEq (AMinus (Ald X) (Ald Y)) (APlus (ANum 2) (ANum 4)) THEN
        SKIP
     ELSE
        Y ::= ANum 0
     FI;;
      IFB BLe (ANum 0) (AMinus (ANum 4) (APlus (ANum 2) (ANum 1))) THEN
        Y ::= ANum 0
     ELSE
        SKIP
     FI;;
     WHILE BEq (Ald Y) (ANum 0) DO
        X ::= APlus (Ald X) (ANum 1)
     END)
     (X ::= ANum 9;;
     Y ::= AMinus (Ald X) (ANum 3);;
      IFB BEq (AMinus (Ald X) (Ald Y)) (ANum 6) THEN
        SKIP
```

```
ELSE
    (Y ::= ANum 0)
FI;;
Y ::= ANum 0;;
WHILE BEq (Ald Y) (ANum 0) D0
    X ::= APlus (Ald X) (ANum 1)
END).
Proof. reflexivity. Qed.
```

### 23.4.3 Soundness of Constant Folding

Now we need to show that what we've done is correct. Here's the proof for arithmetic expressions:

```
Theorem fold_constants_aexp_sound:
   atrans_sound fold_constants_aexp.

Proof.
   unfold atrans_sound. intros a. unfold aequiv. intros st.
   aexp_cases (induction a) Case; simpl;

   try reflexivity;

   try (destruct (fold_constants_aexp a1);
      destruct (fold_constants_aexp a2);
      rewrite IHa1; rewrite IHa2; reflexivity). Qed.
```

Exercise: 3 stars, optional (fold\_bexp\_BEq\_informal) Here is an informal proof of the BEq case of the soundness argument for boolean expression constant folding. Read it carefully and compare it to the formal proof that follows. Then fill in the BLe case of the formal proof (without looking at the BEq case, if possible).

Theorem: The constant folding function for booleans, fold\_constants\_bexp, is sound.

*Proof*: We must show that **b** is equivalent to fold\_constants\_bexp, for all boolean expressions **b**. Proceed by induction on **b**. We show just the case where **b** has the form BEq a1 a2.

In this case, we must show beval st (BEq a1 a2) = beval st (fold\_constants\_bexp (BEq a1 a2)). There are two cases to consider:

• First, suppose fold\_constants\_aexp  $a1 = ANum \ n1$  and fold\_constants\_aexp  $a2 = ANum \ n2$  for some n1 and n2.

In this case, we have fold\_constants\_bexp (BEq a1 a2) = if beq\_nat n1 n2 then BTrue else BFalse and beval st (BEq a1 a2) = beq\_nat (aeval st a1) (aeval st a2). By the soundness of constant folding for arithmetic expressions (Lemma fold\_constants\_aexp\_sound), we know aeval st a1 = aeval st (fold\_constants\_aexp\_a1) = aeval st (ANum n1) = n1

and aeval st a2 = aeval st (fold\_constants\_aexp a2 = aeval st (ANum a2 = n2, so beval st (BEq  $a1 a2 = beq_nat$  (aeval a1 = aeval (aeval  $a2 = beq_nat$   $a2 = beq_nat$   $a2 = beq_nat$   $a2 = beq_nat$  a2 = aeval st (if beq\_nat a2 = aeval st (if beq\_nat a2 = aeval st (if beq\_nat a2 = aeval st BTrue else BFalse) = if beq\_nat a2 = aeval st BTrue else beval st BFalse = if beq\_nat a2 = aeval st (if aeval a

#### as required.

• Otherwise, one of fold\_constants\_aexp a1 and fold\_constants\_aexp a2 is not a constant. In this case, we must show beval st (BEq a1 a2) = beval st (BEq (fold\_constants\_aexp a1) (fold\_constants\_aexp a2)), which, by the definition of beval, is the same as showing beq\_nat (aeval st a1) (aeval st a2) = beq\_nat (aeval st (fold\_constants\_aexp a1)) (aeval st (fold\_constants\_aexp a2)). But the soundness of constant folding for arithmetic expressions (fold\_constants\_aexp\_sound) gives us aeval st a1 = aeval st (fold\_constants\_aexp a1) aeval st a2 = aeval st (fold\_constants\_aexp a2), completing the case.

#### Soundness of (0 + n) Elimination, Redux

Exercise: 4 stars, advanced, optional (optimize\_0plus) Recall the definition optimize\_0plus from Imp.v: Fixpoint optimize\_0plus (e:aexp): aexp:= match e with | ANum n => ANum n | APlus (ANum 0) e2 => optimize\_0plus e2 | APlus e1 e2 => APlus (optimize\_0plus e1) (optimize\_0plus e2) | AMinus e1 e2 => AMinus (optimize\_0plus e1) (optimize\_0plus e2) | AMult e1 e2 => AMult (optimize\_0plus e1) (optimize\_0plus e2) end. Note that this function is defined over the old aexps, without states.

Write a new version of this function that accounts for variables, and analogous ones for **bexp**s and commands: optimize\_0plus\_aexp optimize\_0plus\_bexp optimize\_0plus\_com

Prove that these three functions are sound, as we did for  $fold\_constants\_\times$ . (Make sure you use the congruence lemmas in the proof of  $optimize\_0plus\_com$  — otherwise it will be long!)

Then define an optimizer on commands that first folds constants (using fold\_constants\_com) and then eliminates 0 + n terms (using  $optimize\_0plus\_com$ ).

- Give a meaningful example of this optimizer's output.
- Prove that the optimizer is sound. (This part should be *very* easy.)

## 23.5 Proving That Programs Are *Not* Equivalent

Suppose that c1 is a command of the form X := a1;; Y := a2 and c2 is the command X := a1;; Y := a2', where a2' is formed by substituting a1 for all occurrences of X in a2. For example, c1 and c2 might be: c1 = (X := 42 + 53;; Y := Y + X) c2 = (X := 42 + 53;; Y := Y + (42 + 53)) Clearly, this particular c1 and c2 are equivalent. Is this true in general? We will see in a moment that it is not, but it is worthwhile to pause, now, and see if you can find a counter-example on your own.

Here, formally, is the function that substitutes an arithmetic expression for each occurrence of a given variable in another expression:

```
Fixpoint subst_aexp (i: id) (u: aexp) (a: aexp): aexp:= match <math>a with | ANum n \Rightarrow ANum n | Ald i' \Rightarrow if eq_id_dec i i' then u else Ald i' | APlus a1 a2 \Rightarrow APlus (subst_aexp i u a1) (subst_aexp i u a2) | AMinus a1 a2 \Rightarrow AMinus (subst_aexp i u a1) (subst_aexp i u a2) | AMult a1 a2 \Rightarrow AMult (subst_aexp i u a1) (subst_aexp i u a2) end.

Example subst_aexp_ex: subst_aexp_X (APlus (ANum 42) (ANum 42) (APlus (AId Y) (AId X)) = (APlus (AId Y) (APlus (ANum 42) (ANum 42) (ANum 42)).

Proof. reflexivity. Qed.
```

And here is the property we are interested in, expressing the claim that commands c1 and c2 as described above are always equivalent.

```
Definition subst_equiv_property := \forall i1 \ i2 \ a1 \ a2, cequiv (i1 ::= a1;; i2 ::= a2) (i1 ::= a1;; i2 ::= subst_aexp \ i1 \ a1 \ a2).

Sadly, the property does not always hold.

Theorem: It is not the case that, for all i1, i2, a1, and a2, cequiv (i1 ::= a1;; i2 ::= a2) (i1 ::= a1;; i2 ::= subst_aexp i1 a1 a2). ]] Proof: Suppose, for a contradiction, that for all
```

i1, i2, a1, and a2, we have cequiv (i1 ::= a1;; i2 ::= a2) (i1 ::= a1;; i2 ::= subst\_aexp i1 a1 a2). Consider the following program: X ::= APlus (AId X) (ANum 1);; Y ::= AId X Note that (X ::= APlus (AId X) (ANum 1);;  $Y ::= AId X) / empty_state || st1, where <math>st1 = \{X | -> 1, Y | -> 1\}$ .

By our assumption, we know that cequiv  $(X ::= APlus (AId X) (ANum 1);; Y ::= AId X) (X ::= APlus (AId X) (ANum 1);; Y ::= APlus (AId X) (ANum 1)) so, by the definition of cequiv, we have <math>(X ::= APlus (AId X) (ANum 1);; Y ::= APlus (AId X) (ANum 1)) / empty_state || st1. But we can also derive <math>(X ::= APlus (AId X) (ANum 1);; Y ::= APlus (AId X) (ANum 1)) / empty_state || st2, where <math>st2 = \{ X \mid -> 1, Y \mid -> 2 \}$ . Note that  $st1 \neq st2$ ; this is a contradiction, since **ceval** is deterministic!  $\square$ 

```
Theorem subst_inequiv :
  ¬ subst_equiv_property.
Proof.
  unfold subst_equiv_property.
  intros Contra.
  remember (X ::= APlus (Ald X) (ANum 1);;
             Y ::= Ald X
      as c1.
  remember (X ::= APlus (Ald X) (ANum 1);;
             Y ::= APlus (Ald X) (ANum 1))
      as c2.
  assert (cequiv c1 c2) by (subst; apply Contra).
  remember (update (update empty_state X 1) Y 1) as st1.
  remember (update (update empty_state X 1) Y 2) as st2.
  assert (H1: c1 / empty_state | | st1);
  assert (H2: c2 / \text{empty\_state} \mid \mid st2);
  try (subst;
       apply E_Seq with (st' := (update empty\_state X 1));
       apply E_Ass; reflexivity).
  apply H in H1.
  assert (Hcontra: st1 = st2)
    by (apply (ceval_deterministic c2 empty_state); assumption).
  assert (Hcontra': st1 Y = st2 Y)
    by (rewrite Hcontra; reflexivity).
  subst. inversion Hcontra'. Qed.
```

Exercise: 4 stars, optional (better\_subst\_equiv) The equivalence we had in mind above was not complete nonsense – it was actually almost right. To make it correct, we just need to exclude the case where the variable X occurs in the right-hand-side of the first assignment statement.

```
Inductive var_not_used_in_aexp(X:id) : aexp \rightarrow Prop :=
```

```

       var_not_used_in_aexp X (AMult a1 a2).
Lemma aeval_weakening : \forall i \ st \ a \ ni,
  var\_not\_used\_in\_aexp i a \rightarrow
  aeval (update st \ i \ ni) a = aeval \ st \ a.
Proof.
   Admitted.
   Using var_not_used_in_aexp, formalize and prove a correct verson of subst_equiv_property.
   Exercise: 3 stars, optional (inequiv_exercise) Prove that an infinite loop is not equiv-
alent to SKIP
Theorem inequiv_exercise:
  ¬ cequiv (WHILE BTrue DO SKIP END) SKIP.
Proof.
   Admitted.
```

## 23.6 Extended exercise: Non-deterministic Imp

As we have seen (in theorem ceval\_deterministic in the Imp chapter), Imp's evaluation relation is deterministic. However, non-determinism is an important part of the definition of many real programming languages. For example, in many imperative languages (such as C and its relatives), the order in which function arguments are evaluated is unspecified. The program fragment x = 0; f(++x, x) might call f with arguments (1, 0) or (1, 1), depending how the compiler chooses to order things. This can be a little confusing for programmers, but it gives the compiler writer useful freedom.

In this exercise, we will extend Imp with a simple non-deterministic command and study how this change affects program equivalence. The new command has the syntax HAVOC X, where X is an identifier. The effect of executing HAVOC X is to assign an arbitrary number to the variable X, non-deterministically. For example, after executing the program: HAVOC Y;; Z ::= Y \* 2 the value of Y can be any number, while the value of Z is twice that of Y (so Z is always even). Note that we are not saying anything about the probabilities of the outcomes – just that there are (infinitely) many different outcomes that can possibly happen after executing this non-deterministic code.

In a sense a variable on which we do *HAVOC* roughly corresponds to an unitialized variable in the C programming language. After the *HAVOC* the variable holds a fixed but arbitrary number. Most sources of nondeterminism in language definitions are there precisely because programmers don't care which choice is made (and so it is good to leave it open to the compiler to choose whichever will run faster).

We call this new language Himp ("Imp extended with HAVOC").

Module HIMP.

To formalize the language, we first add a clause to the definition of commands.

```
Inductive com : Type :=
   CSkip : com
    CAss : id \rightarrow aexp \rightarrow com
   \mathsf{CSeq} : \mathsf{com} \to \mathsf{com} \to \mathsf{com}
    \mathsf{Clf}: \mathsf{bexp} \to \mathsf{com} \to \mathsf{com} \to \mathsf{com}
   CWhile : bexp \rightarrow com \rightarrow com
   CHavoc : id \rightarrow com.
Tactic Notation "com_cases" tactic(first) ident(c) :=
  first;
   Case\_aux \ c "SKIP" | Case\_aux \ c "::=" | Case\_aux \ c ";;"
   Case_aux c "IFB" | Case_aux c "WHILE" | Case_aux c "HAVOC" ].
Notation "'SKIP'" :=
  CSkip.
Notation "X '::=' a" :=
  (CAss X a) (at level 60).
Notation "c1;; c2" :=
  (CSeq c1 c2) (at level 80, right associativity).
Notation "'WHILE' b 'DO' c 'END'" :=
  (CWhile b c) (at level 80, right associativity).
Notation "'IFB' e1 'THEN' e2 'ELSE' e3 'FI'" :=
  (Clf e1 e2 e3) (at level 80, right associativity).
Notation "'HAVOC' l" := (CHavoc l) (at level 60).
```

Exercise: 2 stars (himp\_ceval) Now, we must extend the operational semantics. We have provided a template for the ceval relation below, specifying the big-step semantics.

What rule(s) must be added to the definition of **ceval** to formalize the behavior of the HAVOC command?

```
Reserved Notation "c1 '/' st '||' st'" (at level 40, st at level 39).
Inductive ceval : com \rightarrow state \rightarrow state \rightarrow Prop :=
   \mid \mathsf{E\_Skip} : \forall \ st : \mathsf{state}, \ \mathsf{SKIP} \ / \ st \mid \mid \ st
   \mid \mathsf{E}_{-}\mathsf{Ass} : \forall \ (st : \mathsf{state}) \ (a1 : \mathsf{aexp}) \ (n : \mathsf{nat}) \ (X : \mathsf{id}),
                   aeval st a1 = n \rightarrow (X ::= a1) / st \mid \mid update st X n
   \mid \mathsf{E}_{-}\mathsf{Seq} : \forall (c1 \ c2 : \mathsf{com}) (st \ st' \ st'' : \mathsf{state}),
                   c1 / st \mid \mid st' \rightarrow c2 / st' \mid \mid st'' \rightarrow (c1; c2) / st \mid \mid st''
   | E_{-}IfTrue : \forall (st st' : state) (b1 : bexp) (c1 c2 : com),
                        beval st b1 = true \rightarrow
                        c1 / st \mid \mid st' \rightarrow (\text{IFB } b1 \text{ THEN } c1 \text{ ELSE } c2 \text{ FI}) / st \mid \mid st'
   \mid \mathsf{E}_{\mathsf{L}}\mathsf{IfFalse} : \forall (st \ st' : \mathsf{state}) \ (b1 : \mathsf{bexp}) \ (c1 \ c2 : \mathsf{com}),
                         beval st b1 = false \rightarrow
                         c2 / st \mid \mid st' \rightarrow \text{(IFB } b1 \text{ THEN } c1 \text{ ELSE } c2 \text{ FI)} / st \mid \mid st'
   \mid \mathsf{E}_{-}\mathsf{WhileEnd} : \forall \ (b1 : \mathsf{bexp}) \ (st : \mathsf{state}) \ (c1 : \mathsf{com}),
                           beval st b1 = false \rightarrow (WHILE b1 DO c1 END) / st | | st
   | E_{\text{-}}WhileLoop : \forall (st st' st'' : state) (b1 : bexp) (c1 : com),
                            beval st b1 = true \rightarrow
                             c1 / st \mid \mid st' \rightarrow
                             (WHILE b1 DO c1 END) / st' || st'' \rightarrow
                             (WHILE b1 DO c1 END) / st \mid \mid st"
   where "c1 '/' st '||' st'" := (ceval c1 \ st \ st').
Tactic Notation "ceval_cases" tactic(first) ident(c) :=
   first:
     Case_aux c "E_Skip" | Case_aux c "E_Ass" | Case_aux c "E_Seq"
     Case_aux c "E_IfTrue" | Case_aux c "E_IfFalse"
   | Case_aux c "E_WhileEnd" | Case_aux c "E_WhileLoop"
].
     As a sanity check, the following claims should be provable for your definition:
Example havoc_example1 : (HAVOC X) / empty_state | | update empty_state X 0.
Proof.
     Admitted.
Example havoc_example2:
   (SKIP;; HAVOC Z) / empty_state || update empty_state Z 42.
Proof.
     Admitted.
```

Finally, we repeat the definition of command equivalence from above:

```
Definition cequiv (c1 \ c2 : \mathbf{com}) : \mathsf{Prop} := \forall \ st \ st' : \mathsf{state}, \ c1 \ / \ st \ || \ st' \leftrightarrow c2 \ / \ st \ || \ st'.
```

This definition still makes perfect sense in the case of always terminating programs, so let's apply it to prove some non-deterministic programs equivalent or non-equivalent.

```
Exercise: 3 stars (havoc_swap) Are the following two programs equivalent?
Definition pXY :=
   HAVOC X;; HAVOC Y.
Definition pYX :=
   HAVOC Y;; HAVOC X.
   If you think they are equivalent, prove it. If you think they are not, prove that.
```

Theorem pXY\_cequiv\_pYX :
 cequiv pXY pYX ∨ ¬cequiv pXY pYX.

Proof. Admitted.

Exercise: 4 stars, optional (havoc\_copy) Are the following two programs equivalent?

```
Definition ptwice :=
  HAVOC X;; HAVOC Y.
Definition pcopy :=
  HAVOC X;; Y ::= Ald X.
```

If you think they are equivalent, then prove it. If you think they are not, then prove that. (Hint: You may find the assert tactic useful.)

```
Theorem ptwice_cequiv_pcopy : cequiv ptwice pcopy \lor \neg cequiv ptwice pcopy. Proof. Admitted.
```

The definition of program equivalence we are using here has some subtle consequences on programs that may loop forever. What **cequiv** says is that the set of possible *terminating* outcomes of two equivalent programs is the same. However, in a language with non-determinism, like Himp, some programs always terminate, some programs always diverge, and some programs can non-deterministically terminate in some runs and diverge in others. The final part of the following exercise illustrates this phenomenon.

Exercise: 5 stars, advanced (havoc\_diverge) Prove the following program equivalences and non-equivalences, and try to understand why the cequiv definition has the behavior it has on these examples.

```
\begin{array}{l} {\tt Definition}\; {\tt p1}: \; {\tt com} := \\ {\tt WHILE}\; ({\tt BNot}\; ({\tt BEq}\; ({\tt Ald}\; {\tt X})\; ({\tt ANum}\; 0))) \; {\tt DO} \end{array}
```

```
HAVOC Y;;
    X ::= APlus (Ald X) (ANum 1)
  END.
Definition p2 : com :=
  WHILE (BNot (BEq (Ald X) (ANum 0))) DO
    SKIP
  END.
Theorem p1_p2_equiv : cequiv p1 p2.
Proof. Admitted.
Definition p3 : com :=
  Z ::= ANum 1;;
  WHILE (BNot (BEq (Ald X) (ANum 0))) DO
    HAVOC X;;
    HAVOC Z
  END.
Definition p4 : com :=
  X ::= (ANum 0);;
  Z ::= (ANum 1).
Theorem p3_p4_inequiv : ¬ cequiv p3 p4.
Proof. Admitted.
Definition p5 : com :=
  WHILE (BNot (BEq (Ald X) (ANum 1))) DO
    HAVOC X
  END.
Definition p6 : com :=
  X ::= ANum 1.
Theorem p5_p6_equiv : cequiv p5 p6.
Proof. Admitted.
   End HIMP.
```

# 23.7 Doing Without Extensionality (Optional)

Purists might object to using the *functional\_extensionality* axiom. In general, it can be quite dangerous to add axioms, particularly several at once (as they may be mutually inconsistent). In fact, *functional\_extensionality* and excluded\_middle can both be assumed without any problems, but some Coq users prefer to avoid such "heavyweight" general techniques, and instead craft solutions for specific problems that stay within Coq's standard logic.

For our particular problem here, rather than extending the definition of equality to do what we want on functions representing states, we could instead give an explicit notion of equivalence on states. For example:

```
Definition stequiv (st1 \ st2 : state) : Prop := \forall (X:id), st1 \ X = st2 \ X.
Notation "st1 '~' st2" := (stequiv st1 \ st2) (at level 30).
```

It is easy to prove that **stequiv** is an *equivalence* (i.e., it is reflexive, symmetric, and transitive), so it partitions the set of all states into equivalence classes.

```
Exercise: 1 star, optional (stequiv_refl) Lemma stequiv_refl: \forall (st: state),
  st \neg st.
Proof.
   Admitted.
   Exercise: 1 star, optional (stequiv_sym) Lemma stequiv_sym : \forall (st1 st2 : state),
  st1 \neg st2 \rightarrow
  st2 \neg st1.
Proof.
   Admitted.
   Exercise: 1 star, optional (stequiv_trans) Lemma stequiv_trans: \forall (st1 st2 st3:
state),
  st1 \neg st2 \rightarrow
  st2 \neg st3 \rightarrow
  st1 \neg st3.
Proof.
   Admitted.
   Another useful fact...
Exercise: 1 star, optional (stequiv_update) Lemma stequiv_update: \forall (st1 st2: state),
  st1 \neg st2 \rightarrow
  \forall (X:id) (n:nat),
  update st1 \ X \ n \neg update st2 \ X \ n.
Proof.
    Admitted.
```

It is then straightforward to show that aeval and beval behave uniformly on all members of an equivalence class:

```
Exercise: 2 stars, optional (stequiv_aeval) Lemma stequiv_aeval : \forall (st1 st2 : state),
  st1 \neg st2 \rightarrow
  \forall (a:aexp), aeval st1 \ a = aeval st2 \ a.
Proof.
   Admitted.
   Exercise: 2 stars, optional (stequiv_beval) Lemma stequiv_beval: \forall (st1 st2: state),
  st1 \neg st2 \rightarrow
  \forall (b: \mathbf{bexp}), \text{ beval } st1 \ b = \text{ beval } st2 \ b.
Proof.
   Admitted.
   We can also characterize the behavior of ceval on equivalent states (this result is a bit
more complicated to write down because ceval is a relation).
Lemma stequiv_ceval: \forall (st1 \ st2 : state),
  st1 \neg st2 \rightarrow
  \forall (c: com) (st1': state),
     (c / st1 \mid | st1') \rightarrow
     \exists st2' : state,
     ((c \mid st2 \mid \mid st2') \land st1' \neg st2').

     destruct (IHCEV1_1 st2 STEQV) as [st2' [P1 EQV1]].
     destruct (IHCEV1_2 st2' EQV1) as [st2'' [P2 EQV2]].
     \exists st2". split.
       apply E_WhileLoop with st2'. rewrite \leftarrow H. symmetry.
       apply stequiv_beval. assumption. assumption. assumption.
       assumption.
Qed.
   Now we need to redefine cequiv to use \neg instead of =. It is not completely trivial to
do this in a way that keeps the definition simple and symmetric, but here is one approach
(thanks to Andrew McCreight). We first define a looser variant of || that "folds in" the notion
of equivalence.
Reserved Notation "c1 '/' st '||'' st'" (at level 40, st at level 39).
Inductive ceval': com \rightarrow state \rightarrow state \rightarrow Prop :=
  \mid \mathsf{E}_{-}\mathsf{equiv} : \forall \ c \ st \ st' \ st'',
     c / st \mid \mid st' \rightarrow
     st' \neg st'' \rightarrow
     c / st || ' st''
  where "c1 '/' st '||'' st'" := (ceval' c1 \ st \ st').
   Now the revised definition of cequiv' looks familiar:
Definition cequiv (c1 \ c2 : \mathbf{com}) : \mathsf{Prop} :=
  \forall (st \ st' : state),
     (c1 / st | | , st') \leftrightarrow (c2 / st | | , st').
    A sanity check shows that the original notion of command equivalence is at least as strong
as this new one. (The converse is not true, naturally.)
Lemma cequiv_cequiv': \forall (c1 c2: com),
  cequiv c1 c2 \rightarrow cequiv c1 c2.
Proof.
  unfold cequiv, cequiv'; split; intros.
     inversion H\theta; subst. apply E_equiv with st'\theta.
     apply (H \ st \ st'\theta); assumption. assumption.
```

```
inversion H\theta; subst. apply E_equiv with st'\theta.
    apply (H \ st \ st'0). assumption. assumption.
Qed.
Exercise: 2 stars, optional (identity_assignment') Finally, here is our example once
more... (You can complete the proof.)
Example identity_assignment':
  cequiv' SKIP (X ::= Ald X).
Proof.
    unfold cequiv'. intros. split; intros.
    Case "->".
      inversion H; subst; clear H. inversion H\theta; subst.
      apply E_equiv with (update st'\theta \times (st'\theta \times)).
      constructor. reflexivity. apply stequiv_trans with st'0.
      unfold stequiv. intros. apply update_same.
      reflexivity. assumption.
    Case "<-".
   Admitted.
```

On the whole, this explicit equivalence approach is considerably harder to work with than relying on functional extensionality. (Coq does have an advanced mechanism called "setoids" that makes working with equivalences somewhat easier, by allowing them to be registered with the system so that standard rewriting tactics work for them almost as well as for equalities.) But it is worth knowing about, because it applies even in situations where the equivalence in question is *not* over functions. For example, if we chose to represent state mappings as binary search trees, we would need to use an explicit equivalence of this kind.

## 23.8 Additional Exercises

Exercise: 4 stars, optional (for\_while\_equiv) This exercise extends the optional  $add\_for\_loop$  exercise from Imp.v, where you were asked to extend the language of commands with C-style for loops. Prove that the command: for (c1; b; c2) { c3 } is equivalent to: c1; WHILE b DO c3; c2 END  $\Box$ 

Exercise: 3 stars, optional (swap\_noninterfering\_assignments) Theorem swap\_noninterfering\_assignments  $\forall l1 l2 a1 a2$ ,

```
l1 \neq l2 \rightarrow

var_not_used_in_aexp l1 a2 \rightarrow

var_not_used_in_aexp l2 a1 \rightarrow

cequiv

(l1 ::= a1;; l2 ::= a2)
```

```
\begin{array}{c} (\mathit{l2} ::= \mathit{a2}\,;;\; \mathit{l1} ::= \mathit{a1}\,). \\ \mathsf{Proof}. \\ \mathit{Admitted}. \\ \Box \end{array}
```

# Chapter 24

# Library Extraction

## 24.1 Extraction: Extracting ML from Coq

## 24.2 Basic Extraction

In its simplest form, program extraction from Coq is completely straightforward.

First we say what language we want to extract into. Options are OCaml (the most mature), Haskell (which mostly works), and Scheme (a bit out of date).

Extraction Language Ocaml.

Now we load up the Coq environment with some definitions, either directly or by importing them from other modules.

Require Import SfLib.

Require Import ImpCEvalFun.

Finally, we tell Coq the name of a definition to extract and the name of a file to put the extracted code into.

Extraction "imp1.ml" ceval\_step.

When Coq processes this command, it generates a file imp1.ml containing an extracted version of ceval\_step, together with everything that it recursively depends on. Have a look at this file now.

## 24.3 Controlling Extraction of Specific Types

We can tell Coq to extract certain Inductive definitions to specific OCaml types. For each one, we must say

- how the Coq type itself should be represented in OCaml, and
- how each constructor should be translated.

```
Extract Inductive bool ⇒ "bool" [ "true" "false" ].
```

Also, for non-enumeration types (where the constructors take arguments), we give an OCaml expression that can be used as a "recursor" over elements of the type. (Think Church numerals.)

```
Extract Inductive nat \Rightarrow "int"
[ "0" "(fun x -> x + 1)" ]
"(fun zero succ n -> if n=0 then zero () else succ (n-1))".
```

We can also extract defined constants to specific OCaml terms or operators.

```
Extract Constant plus \Rightarrow "( + )".

Extract Constant mult \Rightarrow "( * )".

Extract Constant beq_nat \Rightarrow "( = )".
```

Important: It is entirely *your responsibility* to make sure that the translations you're proving make sense. For example, it might be tempting to include this one Extract Constant minus => "( - )". but doing so could lead to serious confusion! (Why?)

```
Extraction "imp2.ml" ceval_step.
```

Have a look at the file imp2.ml. Notice how the fundamental definitions have changed from imp1.ml.

## 24.4 A Complete Example

To use our extracted evaluator to run Imp programs, all we need to add is a tiny driver program that calls the evaluator and somehow prints out the result.

For simplicity, we'll print results by dumping out the first four memory locations in the final state.

Also, to make it easier to type in examples, let's extract a parser from the ImpParser Coq module. To do this, we need a few more declarations to set up the right correspondence between Coq strings and lists of OCaml characters.

```
Require Import Ascii String. Extract Inductive ascii \Rightarrow char [ "(* If this appears, you're using Ascii internals. Please don't *) (fun (b0,b1,b2,b3,b4,b5,b6,b7) -> let f b i = if b then 1 lsl i else 0 in Char.chr (f b0 0 + f b1 1 + f b2 2 + f b3 3 + f b4 4 + f b5 5 + f b6 6 + f b7 7))" ] "(* If this appears, you're using Ascii internals. Please don't *) (fun f c -> let n = Char.code c in let h i = (n land (1 lsl i)) <> 0 in f (h 0) (h 1) (h 2) (h 3) (h 4) (h 5) (h 6) (h 7))". Extract Constant zero \Rightarrow "'\000'". Extract Constant one \Rightarrow "'\001'". Extract Constant shift \Rightarrow "fun b c -> Char.chr (((Char.code c) lsl 1) land 255 + if b then 1 else 0)".
```

Extract Inlined Constant ascii\_dec  $\Rightarrow$  "(=)".

We also need one more variant of booleans.

Extract Inductive sumbool  $\Rightarrow$  "bool" ["true" "false"].

The extraction is the same as always.

Require Import Imp.

Require Import ImpParser.

Extraction "imp.ml" empty\_state ceval\_step parse.

Now let's run our generated Imp evaluator. First, have a look at *impdriver.ml*. (This was written by hand, not extracted.)

Next, compile the driver together with the extracted code and execute it, as follows.

```
ocamlc -w -20 -w -26 -o impdriver imp.mli imp.ml impdriver.ml ./impdriver
```

(The -w flags to ocamle are just there to suppress a few spurious warnings.)

### 24.5 Discussion

Since we've proved that the ceval\_step function behaves the same as the ceval relation in an appropriate sense, the extracted program can be viewed as a *certified* Imp interpreter. (Of course, the parser is not certified in any interesting sense, since we didn't prove anything about it.)

## Chapter 25

# Library ImpCEvalFun

## 25.1 ImpCEvalFun: Evaluation Function for Imp

#### 25.1.1 Evaluation Function

```
Require Import Imp.
```

Here's a first try at an evaluation function for commands, omitting WHILE.

```
Fixpoint ceval_step1 (st : state) (c : com) : state :=
  match c with
     \mid SKIP \Rightarrow
          st
     | l ::= a1 \Rightarrow
          update st l (aeval st a1)
     |c1;;c2\Rightarrow
          let st' := ceval\_step1 \ st \ c1 in
          ceval_step1 st ' c2
     | IFB b THEN c1 ELSE c2 FI \Rightarrow
          if (beval st b)
             then ceval_step1 st c1
             else ceval_step1 st c2
     | WHILE b1 DO c1 END \Rightarrow
          st
  end.
```

In a traditional functional programming language like ML or Haskell we could write the WHILE case as follows:

```
| WHILE b1 D0 c1 END =>
   if (beval st b1)
     then ceval_step1 st (c1;; WHILE b1 D0 c1 END)
   else st
```

Coq doesn't accept such a definition (Error: Cannot guess decreasing argument of fix) because the function we want to define is not guaranteed to terminate. Indeed, the changed ceval\_step1 function applied to the loop program from Imp.v would never terminate. Since Coq is not just a functional programming language, but also a consistent logic, any potentially non-terminating function needs to be rejected. Here is an invalid(!) Coq program showing what would go wrong if Coq allowed non-terminating recursive functions:

```
Fixpoint loop_false (n : nat) : False := loop_false n.
```

That is, propositions like **False** would become provable (e.g. *loop\_false* 0 would be a proof of **False**), which would be a disaster for Coq's logical consistency.

Thus, because it doesn't terminate on all inputs, the full version of ceval\_step1 cannot be written in Coq – at least not without one additional trick...

Second try, using an extra numeric argument as a "step index" to ensure that evaluation always terminates.

```
Fixpoint ceval_step2 (st : state) (c : com) (i : nat) : state :=
  match i with
    0 \Rightarrow \text{empty\_state}
   \mid S i' \Rightarrow
     match c with
        \mid SKIP \Rightarrow
              st
        | l ::= a1 \Rightarrow
              update st l (aeval st a1)
        | c1 ;; c2 \Rightarrow
              let st' := \text{ceval\_step2} \ st \ c1 \ i' in
              ceval_step2 st' c2 i'
        | IFB b THEN c1 ELSE c2 FI \Rightarrow
              if (beval st b)
                 then ceval_step2 st c1 i'
                 else ceval_step2 st c2 i'
        | WHILE b1 DO c1 END \Rightarrow
              if (beval st b1)
              then let st' := \text{ceval\_step2} \ st \ c1 \ i' in
                     ceval_step2 st ' c i '
              else st
     end
  end.
```

*Note*: It is tempting to think that the index i here is counting the "number of steps of evaluation." But if you look closely you'll see that this is not the case: for example, in the rule for sequencing, the same i is passed to both recursive calls. Understanding the exact way that i is treated will be important in the proof of ceval\_ceval\_step, which is given as an exercise below.

Third try, returning an **option state** instead of just a **state** so that we can distinguish between normal and abnormal termination.

```
Fixpoint ceval_step3 (st : state) (c : com) (i : nat)
                            : option state :=
  match i with
    O \Rightarrow None
  \mid S i' \Rightarrow
     match c with
        | SKIP \Rightarrow
              Some st
        | l ::= a1 \Rightarrow
              Some (update st\ l\ (aeval\ st\ a1))
        | c1 ;; c2 \Rightarrow
              match (ceval_step3 st c1 i') with
              | Some st' \Rightarrow \text{ceval\_step3} st' c2 i'
              | None \Rightarrow None
              end
        | IFB b THEN c1 ELSE c2 FI \Rightarrow
              if (beval st \ b)
                 then ceval_step3 st c1 i'
                 else ceval_step3 st c2 i'
        | WHILE b1 DO c1 END \Rightarrow
              if (beval st b1)
              then match (ceval_step3 st c1 i') with
                      | Some st' \Rightarrow \text{ceval\_step3 } st' \ c \ i'
                     | None \Rightarrow None |
                     end
              else Some st
     end
  end.
```

We can improve the readability of this definition by introducing a bit of auxiliary notation to hide the "plumbing" involved in repeatedly matching against optional states.

```
Notation "'LETOPT' \mathbf{x} <== \mathrm{e}1 'IN' \mathrm{e}2" := (\mathrm{match}\ e1\ \mathrm{with} \\ |\ \mathsf{Some}\ x \Rightarrow e2\ \\ |\ \mathsf{None} \Rightarrow \mathsf{None} \\ \mathrm{end}) \\ (\mathrm{right}\ \mathsf{associativity},\ \mathsf{at}\ \mathsf{level}\ 60). Fixpoint \mathsf{ceval\_step}\ (st:\mathsf{state})\ (c:\mathsf{com})\ (i:\mathsf{nat}) \\ :\ \mathsf{option}\ \mathsf{state} := \\ \mathsf{match}\ i\ \mathsf{with}
```

```
\mid \mathsf{O} \Rightarrow \mathsf{None}
  |Si' \Rightarrow
     {\tt match}\ c\ {\tt with}
        | SKIP \Rightarrow
              Some st
        | l ::= a1 \Rightarrow
              Some (update st\ l (aeval st\ a1))
        |c1;;c2\Rightarrow
              LETOPT st' \le cval\_step st c1 i' IN
              ceval_step st' c2 i'
        | IFB b THEN c1 ELSE c2 FI \Rightarrow
              if (beval st \ b)
                then ceval_step st \ c1 \ i'
                 else ceval_step st c2 i'
        | WHILE b1 DO c1 END \Rightarrow
              if (beval st b1)
              then LETOPT st' \le cval\_step st c1 i' IN
                     ceval\_step st' c i'
              else Some st
     end
  end.
Definition test_ceval (st:state) (c:com) :=
  match ceval_step st\ c\ 500 with
  | None \Rightarrow None
  Some st \Rightarrow Some (st X, st Y, st Z)
  end.
```

Exercise: 2 stars (pup\_to\_n) Write an Imp program that sums the numbers from 1 to X (inclusive: 1 + 2 + ... + X) in the variable Y. Make sure your solution satisfies the test that follows.

```
Definition pup_to_n : com :=
   admit.
```

**Exercise: 2 stars, optional (peven)** Write a *While* program that sets Z to 0 if X is even and sets Z to 1 otherwise. Use *ceval\_test* to test your program.

### 25.1.2 Equivalence of Relational and Step-Indexed Evaluation

As with arithmetic and boolean expressions, we'd hope that the two alternative definitions of evaluation actually boil down to the same thing. This section shows that this is the case. Make sure you understand the statements of the theorems and can follow the structure of the proofs.

```
Theorem ceval_step__ceval: \forall c \ st \ st',
      (\exists i, \text{ ceval\_step } st \ c \ i = \text{Some } st') \rightarrow
      c / st || st'.
Proof.
  intros c st st' H.
  inversion H as [i E].
  clear H.
  generalize dependent st'.
  generalize dependent st.
  generalize dependent c.
  induction i as [|i'|].
  Case "i = 0 - contradictory".
    intros c st st H. inversion H.
  Case "i = S i".
    intros c st st' H.
    com_cases (destruct c) SCase;
            simpl in H; inversion H; subst; clear H.
       SCase "SKIP". apply E_Skip.
       SCase "::=". apply E_Ass. reflexivity.
       SCase "::".
         destruct (ceval_step st c1 i') eqn:Heqr1.
         SSCase "Evaluation of r1 terminates normally".
           apply E_Seq with s.
             apply IHi'. rewrite Heqr1. reflexivity.
              apply IHi'. simpl in H1. assumption.
         SSCase "Otherwise – contradiction".
           inversion H1.
       SCase "IFB".
         destruct (beval st b) eqn:Heqr.
         SSCase "r = true".
           apply E_lfTrue. rewrite Hegr. reflexivity.
           apply IHi'. assumption.
         SSCase "r = false".
           apply E_lfFalse. rewrite Hegr. reflexivity.
           apply IHi'. assumption.
```

```
SCase \text{ "WHILE". destruct (beval } st \ b) \ eqn : Heqr.
SSCase \text{ "r} = \text{true".}
destruct \text{ (ceval\_step } st \ c \ i') \ eqn : Heqr1.
SSSCase \text{ "r}1 = \text{Some } s".
apply \text{ E\_WhileLoop with } s. \text{ rewrite } Heqr. \text{ reflexivity.}
apply \ IHi'. \text{ rewrite } Heqr1. \text{ reflexivity.}
apply \ IHi'. \text{ simpl in } H1. \text{ assumption.}
SSSCase \text{ "r}1 = \text{None".}
inversion \ H1.
SSCase \text{ "r} = \text{false".}
inversion \ H1.
apply \text{ E\_WhileEnd.}
rewrite \leftarrow Heqr. \text{ subst. reflexivity. } \text{Qed.}
```

Exercise: 4 stars (ceval\_step\_\_ceval\_inf) Write an informal proof of ceval\_step\_\_ceval, following the usual template. (The template for case analysis on an inductively defined value should look the same as for induction, except that there is no induction hypothesis.) Make your proof communicate the main ideas to a human reader; do not simply transcribe the steps of the formal proof.

```
Theorem ceval_step_more: \forall i1 \ i2 \ st \ st' \ c,
  i1 \leq i2 \rightarrow
  ceval_step st \ c \ i1 = Some \ st' \rightarrow
  ceval_step st c i2 = Some st'.
Proof.
induction i1 as [i1']; intros i2 st st' c Hle Hceval.
  Case "i1 = 0".
     simpl in Hceval. inversion Hceval.
  Case "i1 = S i1'".
    destruct i2 as [|i2'|]. inversion Hle.
    assert (Hle': i1' \leq i2') by omega.
     com\_cases (destruct c) SCase.
     SCase "SKIP".
       simpl in Hceval. inversion Hceval.
       reflexivity.
    SCase "::=".
       simpl in Hceval. inversion Hceval.
       reflexivity.
     SCase ";;".
       simpl in Hceval. simpl.
       destruct (ceval_step st c1 i1') eqn:Heqst1'o.
       SSCase "st1'o = Some".
```

```
apply (IHi1' i2') in Heqst1'o; try assumption.
    rewrite Hegst1'o. simpl. simpl in Hceval.
    apply (IHi1' i2') in Hceval; try assumption.
  SSCase "st1'o = None".
    inversion Hceval.
SCase "IFB".
  simpl in Hceval. simpl.
 destruct (beval st b); apply (IHi1' i2') in Heeval; assumption.
SCase "WHILE".
  simpl in Hceval. simpl.
  destruct (beval st b); try assumption.
  destruct (ceval_step st c i1') eqn: Heqst1'o.
  SSCase "st1'o = Some".
    apply (IHi1' i2') in Heqst1'o; try assumption.
    rewrite \rightarrow Heqst1'o. simpl. simpl in Hceval.
    apply (IHi1' i2') in Hceval; try assumption.
  SSCase "i1'o = None".
    simpl in Hceval. inversion Hceval. Qed.
```

Exercise:  $3 \text{ stars (ceval\_ceval\_step})$  Finish the following proof. You'll need ceval\\_step\_more in a few places, as well as some basic facts about  $\leq$  and plus.

```
Theorem ceval__ceval_step: \forall \ c \ st \ st', c \ / \ st \ | \ | \ st' \rightarrow \exists \ i, ceval_step st \ c \ i = Some \ st'.

Proof.

intros c \ st \ st' \ Hce.
ceval\_cases (induction Hce) Case.
Admitted.
\Box

Theorem ceval_and_ceval_step_coincide: \forall \ c \ st \ st',
c \ / \ st \ | \ st'
\leftrightarrow \exists \ i, ceval_step st \ c \ i = Some \ st'.

Proof.
intros c \ st \ st'.
split. apply ceval\_ceval\_step. apply ceval_step_ceval.
Qed.
```

## 25.1.3 Determinism of Evaluation (Simpler Proof)

Here's a slicker proof showing that the evaluation relation is deterministic, using the fact that the relational and step-indexed definition of evaluation are the same.

```
Theorem ceval_deterministic': \forall \ c \ st \ st1 \ st2, c \ / \ st \ | \ | \ st1 \rightarrow c \ / \ st \ | \ | \ st2 \rightarrow st1 = st2.

Proof.

intros c \ st \ st1 \ st2 \ He1 \ He2.
apply ceval\_ceval\_step in He1.
apply ceval\_ceval\_step in He2.
inversion He1 as [i1 \ E1].
inversion He2 as [i2 \ E2].
apply ceval\_step\_more with (i2 := i1 + i2) in E1. apply ceval\_step\_more with (i2 := i1 + i2) in E2. rewrite E1 in E2. inversion E2. reflexivity. omega. Omega. Qed.
```

## Chapter 26

# Library ImpParser

## 26.1 ImpParser: Lexing and Parsing in Coq

The development of the lmp language in Imp.v completely ignores issues of concrete syntax – how an ascii string that a programmer might write gets translated into the abstract syntax trees defined by the datatypes **aexp**, **bexp**, and **com**. In this file we illustrate how the rest of the story can be filled in by building a simple lexical analyzer and parser using Coq's functional programming facilities.

This development is not intended to be understood in detail: the explanations are fairly terse and there are no exercises. The main point is simply to demonstrate that it can be done. You are invited to look through the code – most of it is not very complicated, though the parser relies on some "monadic" programming idioms that may require a little work to make out – but most readers will probably want to just skip down to the Examples section at the very end to get the punchline.

### 26.2 Internals

```
Require Import SfLib.
Require Import Imp.
Require Import String.
Require Import Ascii.
Open Scope list_scope.
```

## 26.2.1 Lexical Analysis

```
Definition isWhite (c: ascii): bool :=
  let n := nat_of_ascii c in
  orb (orb (beq_nat n 32)
```

```
(\mathsf{beq\_nat}\ n\ 9))
        (orb (beq_nat n 10)
              (beq_nat n 13)).
Notation "x '\leq=?' y" := (ble_nat x y)
  (at level 70, no associativity) : nat\_scope.
Definition isLowerAlpha (c : ascii) : bool :=
  let n := nat\_of\_ascii c in
     andb (97 \le n) (n \le 122).
Definition is Alpha (c : ascii) : bool :=
  let n := \mathsf{nat\_of\_ascii}\ c in
     orb (andb (65 <=? n) (n <=? 90))
          (andb (97 \le n) (n \le 122)).
Definition is Digit (c : ascii) : bool :=
  let n := \mathsf{nat\_of\_ascii}\ c in
      andb (48 \le n) (n \le 57).
Inductive chartype := white | alpha | digit | other.
Definition classifyChar (c : ascii) : chartype :=
  if isWhite c then
     white
  else if is\mathsf{Alpha}\ c then
     alpha
  else if isDigit c then
     digit
  else
     other.
Fixpoint list_of_string (s : string) : list ascii :=
  \mathtt{match}\ s with
  | EmptyString \Rightarrow []
  | String c \ s \Rightarrow c :: (list_of_string s)
  end.
Fixpoint string_of_list (xs : list ascii) : string :=
  fold_right String EmptyString xs.
Definition token := string.
Fixpoint tokenize_helper (cls: chartype) (acc xs: list ascii)

## 26.3 Examples

## Chapter 27

# Library Imp

## 27.1 Imp: Simple Imperative Programs

In this chapter, we begin a new direction that will continue for the rest of the course. Up to now most of our attention has been focused on various aspects of Coq itself, while from now on we'll mostly be using Coq to formalize other things. (We'll continue to pause from time to time to introduce a few additional aspects of Coq.)

Our first case study is a *simple imperative programming language* called Imp, embodying a tiny core fragment of conventional mainstream languages such as C and Java. Here is a familiar mathematical function written in Imp. Z ::= X;; Y ::= 1;; WHILE not (Z = 0) DO Y ::= Y \* Z;; Z ::= Z - 1 END

This chapter looks at how to define the *syntax* and *semantics* of Imp; the chapters that follow develop a theory of *program equivalence* and introduce *Hoare Logic*, a widely used logic for reasoning about imperative programs.

#### Sflib

A minor technical point: Instead of asking Coq to import our earlier definitions from chapter Logic, we import a small library called *Sflib.v*, containing just a few definitions and theorems from earlier chapters that we'll actually use in the rest of the course. This change should be nearly invisible, since most of what's missing from Sflib has identical definitions in the Coq standard library. The main reason for doing it is to tidy the global Coq environment so that, for example, it is easier to search for relevant theorems.

Require Export SfLib.

## 27.2 Arithmetic and Boolean Expressions

We'll present Imp in three parts: first a core language of arithmetic and boolean expressions, then an extension of these expressions with variables, and finally a language of commands including assignment, conditions, sequencing, and loops.

### 27.2.1 Syntax

Module AEXP.

These two definitions specify the abstract syntax of arithmetic and boolean expressions.

```
Inductive aexp: Type:= |ANum: nat \rightarrow aexp |APlus: aexp \rightarrow aexp \rightarrow aexp |AMinus: aexp \rightarrow aexp \rightarrow aexp |AMult: aexp \rightarrow aexp \rightarrow aexp |AMult: aexp \rightarrow aexp \rightarrow aexp.
Inductive bexp: Type:= |BTrue: bexp |BFalse: bexp |BFalse: bexp |BEq: aexp \rightarrow aexp \rightarrow bexp |BLe: aexp \rightarrow aexp \rightarrow bexp |BNot: bexp \rightarrow bexp |BNot: bexp \rightarrow bexp |BAnd: bexp \rightarrow bexp \rightarrow bexp.
```

In this chapter, we'll elide the translation from the concrete syntax that a programmer would actually write to these abstract syntax trees – the process that, for example, would translate the string "1+2\*3" to the AST APlus (ANum 1) (AMult (ANum 2) (ANum 3)). The optional chapter ImpParser develops a simple implementation of a lexical analyzer and parser that can perform this translation. You do *not* need to understand that file to understand this one, but if you haven't taken a course where these techniques are covered (e.g., a compilers course) you may want to skim it.

For comparison, here's a conventional BNF (Backus-Naur Form) grammar defining the same abstract syntax:  $a := nat \mid a + a \mid a - a \mid a * a$ 

```
b ::= true | false | a = a | a <= a | b and b | not b
Compared to the Coq version above...
```

• The BNF is more informal – for example, it gives some suggestions about the surface syntax of expressions (like the fact that the addition operation is written + and is an infix symbol) while leaving other aspects of lexical analysis and parsing (like the relative precedence of +, -, and ×) unspecified. Some additional information – and human intelligence – would be required to turn this description into a formal definition (when implementing a compiler, for example).

The Coq version consistently omits all this information and concentrates on the abstract syntax only.

• On the other hand, the BNF version is lighter and easier to read. Its informality makes it flexible, which is a huge advantage in situations like discussions at the blackboard, where conveying general ideas is more important than getting every detail nailed down precisely.

Indeed, there are dozens of BNF-like notations and people switch freely among them, usually without bothering to say which form of BNF they're using because there is no need to: a rough-and-ready informal understanding is all that's needed.

It's good to be comfortable with both sorts of notations: informal ones for communicating between humans and formal ones for carrying out implementations and proofs.

#### 27.2.2 Evaluation

Evaluating an arithmetic expression produces a number.

```
Fixpoint aeval (a : aexp) : nat :=
  match a with
   ANum n \Rightarrow n
    APlus a1 a2 \Rightarrow (aeval a1) + (aeval a2)
    AMinus a1 a2 \Rightarrow (aeval a1) - (aeval a2)
   AMult a1 \ a2 \Rightarrow (aeval a1) \times (aeval a2)
  end.
Example test_aeval1:
  aeval (APlus (ANum 2) (ANum 2)) = 4.
Proof. reflexivity. Qed.
    Similarly, evaluating a boolean expression yields a boolean.
Fixpoint beval (b : \mathbf{bexp}) : \mathbf{bool} :=
  match b with
    BTrue \Rightarrow true
    BFalse \Rightarrow false
    BEq a1 a2 \Rightarrow beg_nat (aeval a1) (aeval a2)
    BLe a1 a2 \Rightarrow ble_nat (aeval a1) (aeval a2)
    BNot b1 \Rightarrow \text{negb} (beval b1)
   | BAnd b1 b2 \Rightarrow andb (beval b1) (beval b2)
  end.
```

## 27.2.3 Optimization

We haven't defined very much yet, but we can already get some mileage out of the definitions. Suppose we define a function that takes an arithmetic expression and slightly simplifies it, changing every occurrence of 0+e (i.e., (APlus (ANum 0) e) into just e.

```
Fixpoint optimize_0plus (a:aexp): aexp:= match a with | ANum n \Rightarrow ANum n | APlus (ANum 0) e2 \Rightarrow
```

```
optimize_Oplus e2
  | APlus e1 \ e2 \Rightarrow
      APlus (optimize_0plus e1) (optimize_0plus e2)
  | AMinus e1 \ e2 \Rightarrow
      AMinus (optimize_0plus e1) (optimize_0plus e2)
  | AMult e1 \ e2 \Rightarrow
      AMult (optimize_0plus e1) (optimize_0plus e2)
  end.
   To make sure our optimization is doing the right thing we can test it on some examples
and see if the output looks OK.
Example test_optimize_Oplus:
  optimize_Oplus (APlus (ANum 2)
                           (APlus (ANum 0)
                                  (APlus (ANum 0) (ANum 1))))
  = APlus (ANum 2) (ANum 1).
Proof. reflexivity. Qed.
   But if we want to be sure the optimization is correct – i.e., that evaluating an optimized
expression gives the same result as the original – we should prove it.
Theorem optimize_0plus_sound: \forall a,
  aeval (optimize_0plus a) = aeval a.
Proof.
  intros a. induction a.
  Case "ANum". reflexivity.
  Case "APlus". destruct a1.
    SCase "a1 = ANum n". destruct n.
      SSCase "n = 0". simpl. apply IHa2.

      rewrite IHa2. reflexivity.
    SCase "a1 = AMinus a1_1 a1_2".
      simpl. simpl in IHa1. rewrite IHa1.
      rewrite IHa2. reflexivity.
    SCase "a1 = AMult a1_1 a1_2".
      simpl. simpl in IHa1. rewrite IHa1.
      rewrite IHa2. reflexivity.
  Case "AMinus".
    simpl. rewrite IHa1. rewrite IHa2. reflexivity.
  Case "AMult".
    simpl. rewrite IHa1. rewrite IHa2. reflexivity. Qed.
```

## 27.3 Coq Automation

The repetition in this last proof is starting to be a little annoying. If either the language of arithmetic expressions or the optimization being proved sound were significantly more complex, it would begin to be a real problem.

So far, we've been doing all our proofs using just a small handful of Coq's tactics and completely ignoring its powerful facilities for constructing parts of proofs automatically. This section introduces some of these facilities, and we will see more over the next several chapters. Getting used to them will take some energy – Coq's automation is a power tool – but it will allow us to scale up our efforts to more complex definitions and more interesting properties without becoming overwhelmed by boring, repetitive, low-level details.

#### 27.3.1 Tacticals

Tacticals is Coq's term for tactics that take other tactics as arguments – "higher-order tactics," if you will.

#### The repeat Tactical

The repeat tactical takes another tactic and keeps applying this tactic until the tactic fails. Here is an example showing that 100 is even using repeat.

```
Theorem ev100: ev 100.

Proof.

repeat (apply ev_SS). apply ev_0.

Qed.
```

The repeat T tactic never fails; if the tactic T doesn't apply to the original goal, then repeat still succeeds without changing the original goal (it repeats zero times).

```
Theorem ev100': ev 100. Proof.
```

```
repeat (apply ev_0). repeat (apply ev_SS). apply ev_0. Qed.
```

The repeat T tactic does not have any bound on the number of times it applies T. If T is a tactic that always succeeds then repeat T will loop forever (e.g. repeat simpl loops forever since simpl always succeeds). While Coq's term language is guaranteed to terminate, Coq's tactic language is not!

#### The try Tactical

If T is a tactic, then try T is a tactic that is just like T except that, if T fails, try T successfully does nothing at all (instead of failing).

```
Theorem silly1 : \forall ae, aeval ae = aeval ae.
Proof. try reflexivity. Qed.
Theorem silly2 : \forall (P : Prop), P \rightarrow P.
```

```
Proof. intros P HP. try reflexivity. apply HP. Qed.
```

Using try in a completely manual proof is a bit silly, but we'll see below that try is very useful for doing automated proofs in conjunction with the ; tactical.

#### The; Tactical (Simple Form)

In its most commonly used form, the ; tactical takes two tactics as argument: T; T' first performs the tactic T and then performs the tactic T' on each subgoal generated by T.

For example, consider the following trivial lemma:

```
Lemma foo : \forall n, ble_nat 0 n = \text{true}.
Proof.
  intros.
  destruct n.
    Case "n=0". simpl. reflexivity.
    Case "n=Sn'". simpl. reflexivity.
Qed.
   We can simplify this proof using the ; tactical:
Lemma foo': \forall n, ble_nat 0 n = \text{true}.
Proof.
  intros.
  destruct n;
  simpl;
  reflexivity. Qed.
   Using try and; together, we can get rid of the repetition in the proof that was bothering
us a little while ago.
Theorem optimize_0plus_sound': \forall a,
  aeval (optimize_0plus a) = aeval a.
Proof.
  intros a.
  induction a;
    try (simpl; rewrite IHa1; rewrite IHa2; reflexivity).
  Case "ANum". reflexivity.
  Case "APlus".
    destruct a1;
      try (simpl; simpl in IHa1; rewrite IHa1;
            rewrite IHa2; reflexivity).
    SCase "a1 = ANum n". destruct n;
```

```
simpl; rewrite IHa2; reflexivity. Qed.
```

Coq experts often use this "...; try..." idiom after a tactic like induction to take care of many similar cases all at once. Naturally, this practice has an analog in informal proofs.

Here is an informal proof of this theorem that matches the structure of the formal one:

Theorem: For all arithmetic expressions a, aeval (optimize\_0plus a) = aeval a. Proof: By induction on a. The AMinus and AMult cases follow directly from the IH. The remaining cases are as follows:

- Suppose a = ANum n for some n. We must show aeval (optimize\_0plus (ANum n)) = aeval (ANum n). This is immediate from the definition of optimize\_0plus.
- Suppose  $a = APlus \ a1 \ a2$  for some a1 and a2. We must show aeval (optimize\_0plus (APlus a1 a2)) = aeval (APlus a1 a2). Consider the possible forms of a1. For most of them, optimize\_0plus simply calls itself recursively for the subexpressions and rebuilds a new expression of the same form as a1; in these cases, the result follows directly from the IH.

The interesting case is when  $a1 = \mathsf{ANum} \ \mathsf{n}$  for some  $\mathsf{n}$ . If  $\mathsf{n} = \mathsf{ANum} \ \mathsf{0}$ , then optimize\_0plus (APlus a1 a2) = optimize\_0plus a2 and the IH for a2 is exactly what we need. On the other hand, if  $\mathsf{n} = \mathsf{S} \ n'$  for some n', then again optimize\_0plus simply calls itself recursively, and the result follows from the IH.  $\square$ 

This proof can still be improved: the first case (for  $a = ANum\ n$ ) is very trivial – even more trivial than the cases that we said simply followed from the IH – yet we have chosen to write it out in full. It would be better and clearer to drop it and just say, at the top, "Most cases are either immediate or direct from the IH. The only interesting case is the one for APlus..." We can make the same improvement in our formal proof too. Here's how it looks:

#### The; Tactical (General Form)

The ; tactical has a more general than the simple T; T' we've seen above, which is sometimes also useful. If T, T1, ..., Tn are tactics, then  $T; T1 \mid T2 \mid ... \mid Tn$  is a tactic that first performs T and then performs T1 on the first subgoal generated by T, performs T2 on the second subgoal, etc.

So T;T' is just special notation for the case when all of the Ti's are the same tactic; i.e. T;T' is just a shorthand for:  $T;T'\mid T'\mid ...\mid T'$ 

### 27.3.2 Defining New Tactic Notations

Coq also provides several ways of "programming" tactic scripts.

- The Tactic Notation idiom illustrated below gives a handy way to define "shorthand tactics" that bundle several tactics into a single command.
- For more sophisticated programming, Coq offers a small built-in programming language called Ltac with primitives that can examine and modify the proof state. The details are a bit too complicated to get into here (and it is generally agreed that Ltac is not the most beautiful part of Coq's design!), but they can be found in the reference manual, and there are many examples of Ltac definitions in the Coq standard library that you can use as examples.
- There is also an OCaml API, which can be used to build tactics that access Coq's internal structures at a lower level, but this is seldom worth the trouble for ordinary Coq users.

The Tactic Notation mechanism is the easiest to come to grips with, and it offers plenty of power for many purposes. Here's an example.

```
Tactic Notation "simpl_and_try" tactic(c) := simpl; try c.
```

This defines a new tactical called *simpl\_and\_try* which takes one tactic **c** as an argument, and is defined to be equivalent to the tactic **simpl**; **try c**. For example, writing "simpl\_and\_try reflexivity." in a proof would be the same as writing "simpl; try reflexivity."

The next subsection gives a more sophisticated use of this feature...

#### **Bulletproofing Case Analyses**

Being able to deal with most of the cases of an induction or destruct all at the same time is very convenient, but it can also be a little confusing. One problem that often comes up is that *maintaining* proofs written in this style can be difficult. For example, suppose that, later, we extended the definition of **aexp** with another constructor that also required

a special argument. The above proof might break because Coq generated the subgoals for this constructor before the one for APlus, so that, at the point when we start working on the APlus case, Coq is actually expecting the argument for a completely different constructor. What we'd like is to get a sensible error message saying "I was expecting the AFoo case at this point, but the proof script is talking about APlus." Here's a nice trick (due to Aaron Bohannon) that smoothly achieves this.

```
Tactic Notation "aexp_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c "ANum" | Case\_aux \ c "APlus" | Case\_aux \ c "AMinus" | Case\_aux \ c "AMult" ].
```

(Case\_aux implements the common functionality of Case, SCase, SSCase, etc. For example, Case "foo" is defined as Case\_aux Case "foo".)

For example, if a is a variable of type **aexp**, then doing aexp\_cases (induction a) Case will perform an induction on a (the same as if we had just typed induction a) and *also* add a *Case* tag to each subgoal generated by the induction, labeling which constructor it comes from. For example, here is yet another proof of optimize\_Oplus\_sound, using *aexp\_cases*:

```
Theorem optimize_Oplus_sound''': \forall a, aeval (optimize_Oplus a) = aeval a.

Proof.

intros a.

aexp\_cases (induction a) Case;

try (simpl; rewrite IHa1; rewrite IHa2; reflexivity);

try reflexivity.

Case "APlus".

aexp\_cases (destruct a1) SCase;

try (simpl; simpl in IHa1;

rewrite IHa1; rewrite IHa2; reflexivity).

SCase "ANum". destruct n;

simpl; rewrite IHa2; reflexivity. Qed.
```

Exercise: 3 stars (optimize\_0plus\_b) Since the optimize\_0plus tranformation doesn't change the value of aexps, we should be able to apply it to all the aexps that appear in a bexp without changing the bexp's value. Write a function which performs that transformation on bexps, and prove it is sound. Use the tacticals we've just seen to make the proof as elegant as possible.

```
Fixpoint optimize_Oplus_b (b: \mathbf{bexp}): \mathbf{bexp} := admit.
Theorem optimize_Oplus_b_sound : \forall b, beval (optimize_Oplus_b b) = beval b.
Proof.

Admitted.
```

Exercise: 4 stars, optional (optimizer) Design exercise: The optimization implemented by our optimize\_Oplus function is only one of many imaginable optimizations on arithmetic and boolean expressions. Write a more sophisticated optimizer and prove it correct.

### 27.3.3 The omega Tactic

The omega tactic implements a decision procedure for a subset of first-order logic called *Presburger arithmetic*. It is based on the Omega algorithm invented in 1992 by William Pugh.

If the goal is a universally quantified formula made out of

- numeric constants, addition (+ and S), subtraction (- and pred), and multiplication by constants (this is what makes it Presburger arithmetic),
- equality (= and  $\neq$ ) and inequality ( $\leq$ ), and
- the logical connectives  $\land$ ,  $\lor$ ,  $\neg$ , and  $\rightarrow$ ,

then invoking omega will either solve the goal or tell you that it is actually false.

```
Example silly_presburger_example : \forall m \ n \ o \ p, m+n \leq n+o \land o+3=p+3 \rightarrow m \leq p. Proof. intros. omega. Qed.
```

Liebniz wrote, "It is unworthy of excellent men to lose hours like slaves in the labor of calculation which could be relegated to anyone else if machines were used." We recommend using the omega tactic whenever possible.

### 27.3.4 A Few More Handy Tactics

Finally, here are some miscellaneous tactics that you may find convenient.

- clear *H*: Delete hypothesis *H* from the context.
- subst x: Find an assumption x = e or e = x in the context, replace x with e throughout the context and current goal, and clear the assumption.
- subst: Substitute away all assumptions of the form x = e or e = x.

- rename... *into*...: Change the name of a hypothesis in the proof context. For example, if the context includes a variable named x, then rename x *into* y will change all occurrences of x to y.
- assumption: Try to find a hypothesis *H* in the context that exactly matches the goal; if one is found, behave just like apply *H*.
- contradiction: Try to find a hypothesis H in the current context that is logically equivalent to **False**. If one is found, solve the goal.
- constructor: Try to find a constructor c (from some Inductive definition in the current environment) that can be applied to solve the current goal. If one is found, behave like apply c.

We'll see many examples of these in the proofs below.

### 27.4 Evaluation as a Relation

We have presented aeval and beval as functions defined by *Fixpoints*. Another way to think about evaluation – one that we will see is often more flexible – is as a *relation* between expressions and their values. This leads naturally to **Inductive** definitions like the following one for arithmetic expressions...

Module AEVALR\_FIRST\_TRY.

```
Inductive aevalR : aexp \rightarrow nat \rightarrow Prop := | E\_ANum : \forall (n: nat),
aevalR (ANum n) n
| E\_APlus : \forall (e1 e2: aexp) (n1 n2: nat),
aevalR e1 n1 \rightarrow
aevalR (aPlus e1 e2) (n1 + n2)
| E\_AMinus : \forall (e1 e2: aexp) (n1 n2: nat),
aevalR e1 n1 \rightarrow
aevalR e2 n2 \rightarrow
aevalR (AMinus e1 e2) (n1 - n2)
| E\_AMult : \forall (e1 e2: aexp) (n1 n2: nat),
aevalR e1 n1 \rightarrow
aevalR e2 n2 \rightarrow
aevalR e2 n2 \rightarrow
aevalR (AMult e1 e2) (n1 × n2).
```

As is often the case with relations, we'll find it convenient to define infix notation for **aevalR**. We'll write e || n to mean that arithmetic expression e evaluates to value n. (This notation is one place where the limitation to ASCII symbols becomes a little bothersome. The standard notation for the evaluation relation is a double down-arrow. We'll typeset

it like this in the HTML version of the notes and use a double vertical bar as the closest approximation in .v files.)

```
Notation "e'||' n" := (aevalR e n) : type\_scope.
End AEVALR_FIRST_TRY.
```

In fact, Coq provides a way to use this notation in the definition of  $\mathbf{aevalR}$  itself. This avoids situations where we're working on a proof involving statements in the form  $\mathbf{e} \mid\mid \mathbf{n}$  but we have to refer back to a definition written using the form  $\mathbf{aevalR}$   $\mathbf{e}$   $\mathbf{n}$ .

We do this by first "reserving" the notation, then giving the definition together with a declaration of what the notation means.

```
Reserved Notation "e'||' n" (at level 50, left associativity). Inductive \operatorname{aevalR}: \operatorname{aexp} \to \operatorname{nat} \to \operatorname{Prop}:= | \operatorname{E_ANum}: \forall (n:\operatorname{nat}), \quad (\operatorname{ANum}\ n) \mid | \ n \mid \operatorname{E_APlus}: \forall (e1\ e2:\ \operatorname{aexp})\ (n1\ n2:\ \operatorname{nat}), \quad (e1\ ||\ n1) \to (e2\ ||\ n2) \to (\operatorname{APlus}\ e1\ e2)\ ||\ (n1+n2) \mid \operatorname{E_AMinus}: \forall (e1\ e2:\ \operatorname{aexp})\ (n1\ n2:\ \operatorname{nat}), \quad (e1\ ||\ n1) \to (e2\ ||\ n2) \to (\operatorname{AMinus}\ e1\ e2)\ ||\ (n1-n2) \mid \operatorname{E_AMult}: \forall (e1\ e2:\ \operatorname{aexp})\ (n1\ n2:\ \operatorname{nat}), \quad (e1\ ||\ n1) \to (e2\ ||\ n2) \to (\operatorname{AMult}\ e1\ e2)\ ||\ (n1\times n2) \mid \operatorname{E_AMult}: \exists (\operatorname{aevalR}\ e\ n):\ type\_scope.
Tactic Notation "aevalR_cases" tactic(\operatorname{first})\ ident(c):= \operatorname{first}; \quad [\ Case\_aux\ c\ "E\_ANum"\ |\ Case\_aux\ c\ "E\_APlus"\ |\ Case\_aux\ c\ "E_AMult"\ |\ Case\_aux\ c\ "E_AMul
```

### 27.4.1 Inference Rule Notation

In informal discussions, it is convenient write the rules for **aevalR** and similar relations in the more readable graphical form of *inference rules*, where the premises above the line justify the conclusion below the line (we have already seen them in the Prop chapter).

For example, the constructor  $E_APlus... \mid E_APlus$ : for all (e1 e2: aexp) (n1 n2: nat), aevalR e1 n1 -> aevalR e2 n2 -> aevalR (APlus e1 e2) (n1 + n2) ... would be written like this as an inference rule: e1 || n1 e2 || n2

```
(E_APlus) APlus e1 e2 || n1+n2
```

Formally, there is nothing very deep about inference rules: they are just implications. You can read the rule name on the right as the name of the constructor and read each of the linebreaks between the premises above the line and the line itself as  $\rightarrow$ . All the variables mentioned in the rule (e1, n1, etc.) are implicitly bound by universal quantifiers at the beginning. (Such variables are often called metavariables to distinguish them from

the variables of the language we are defining. At the moment, our arithmetic expressions don't include variables, but we'll soon be adding them.) The whole collection of rules is understood as being wrapped in an Inductive declaration (informally, this is either elided or else indicated by saying something like "Let aevalR be the smallest relation closed under the following rules...").

For example, | is the smallest relation closed under these rules:

```
(E_ANum) ANum n || n
  e1 || n1 e2 || n2
(E_APlus) APlus e1 e2 || n1+n2
  e1 || n1 e2 || n2
(E_AMinus) AMinus e1 e2 || n1-n2
  e1 || n1 e2 || n2
```

(E\_AMult) AMult e1 e2 || n1\*n2

#### Equivalence of the Definitions 27.4.2

It is straightforward to prove that the relational and functional definitions of evaluation agree on all possible arithmetic expressions...

```
Theorem aeval_iff_aevalR : \forall a n,
  (a \mid \mid n) \leftrightarrow \text{aeval } a = n.
Proof.
 split.
 Case "->".
   intros H.
   aevalR\_cases (induction H) SCase; simpl.
   SCase "E_ANum".
     reflexivity.
   SCase "E_APlus".
     rewrite IHaevalR1. rewrite IHaevalR2. reflexivity.
   SCase "E_AMinus".
     rewrite IHaevalR1. rewrite IHaevalR2. reflexivity.
   SCase "E_AMult".
     rewrite IHaevalR1. rewrite IHaevalR2. reflexivity.
 Case "<-".
   generalize dependent n.
   aexp_cases (induction a) SCase;
      simpl; intros; subst.
   SCase "ANum".
```

```
apply E_ANum.

$Case "APlus".

apply E_APlus.

apply IHa1. reflexivity.

apply IHa2. reflexivity.

$Case "AMinus".

apply E_AMinus.

apply IHa1. reflexivity.

apply IHa2. reflexivity.

$Case "AMult".

apply E_AMult".

apply E_AMult.

apply IHa1. reflexivity.

Qed.
```

Note: if you're reading the HTML file, you'll see an empty square box instead of a proof for this theorem. You can click on this box to "unfold" the text to see the proof. Click on the unfolded to text to "fold" it back up to a box. We'll be using this style frequently from now on to help keep the HTML easier to read. The full proofs always appear in the .v files.

We can make the proof quite a bit shorter by making more use of tacticals...

```
Theorem aeval_iff_aevalR': \forall a \ n, (a \mid \mid n) \leftrightarrow \text{aeval } a = n.

Proof.

split.

Case \text{"->"}.

intros H; induction H; subst; reflexivity.

Case \text{"<-"}.

generalize dependent n.

induction a; simpl; intros; subst; constructor; try apply IHa1; try apply IHa2; reflexivity.

Qed.
```

Exercise: 3 stars (bevalR) Write a relation bevalR in the same style as aevalR, and prove that it is equivalent to beval.

 $\square$  End AEXP.

## 27.4.3 Computational vs. Relational Definitions

For the definitions of evaluation for arithmetic and boolean expressions, the choice of whether to use functional or relational definitions is mainly a matter of taste. In general, Coq has somewhat better support for working with relations. On the other hand, in some sense function definitions carry more information, because functions are necessarily deterministic and defined on all arguments; for a relation we have to show these properties explicitly if we need them. Functions also take advantage of Coq's computations mechanism.

However, there are circumstances where relational definitions of evaluation are preferable to functional ones.

#### Module AEVALR\_DIVISION.

For example, suppose that we wanted to extend the arithmetic operations by considering also a division operation:

```
Inductive aexp : Type :=
| ANum : nat \rightarrow aexp
| APlus : aexp \rightarrow aexp \rightarrow aexp
| AMinus : aexp \rightarrow aexp \rightarrow aexp
| AMult : aexp \rightarrow aexp \rightarrow aexp
| ADiv : aexp \rightarrow aexp \rightarrow aexp
```

Extending the definition of aeval to handle this new operation would not be straightforward (what should we return as the result of ADiv (ANum 5) (ANum 0)?). But extending aevalR is straightforward.

```
Inductive aevalR: aexp \rightarrow nat \rightarrow Prop :=
   \mid \mathsf{E\_ANum} : \forall (n:\mathsf{nat}),
           (ANum n) || n
   \mid \mathsf{E\_APlus} : \forall (a1 \ a2 : \mathsf{aexp}) (n1 \ n2 : \mathsf{nat}),
          (a1 \mid \mid n1) \rightarrow (a2 \mid \mid n2) \rightarrow (APlus \ a1 \ a2) \mid \mid (n1 + n2)
   \mid \mathsf{E\_AMinus} : \forall (a1 \ a2 : \mathsf{aexp}) (n1 \ n2 : \mathsf{nat}),
          (a1 \mid \mid n1) \rightarrow (a2 \mid \mid n2) \rightarrow (AMinus \ a1 \ a2) \mid \mid (n1 - n2)
   \mid \mathsf{E\_AMult} : \forall (a1 \ a2: \mathbf{aexp}) (n1 \ n2: \mathbf{nat}),
          (a1 \mid \mid n1) \rightarrow (a2 \mid \mid n2) \rightarrow (AMult \ a1 \ a2) \mid \mid (n1 \times n2)
   \mid \mathsf{E\_ADiv} : \forall (a1 \ a2: \mathbf{aexp}) (n1 \ n2 \ n3: \mathbf{nat}),
          (a1 \mid \mid n1) \rightarrow (a2 \mid \mid n2) \rightarrow (\text{mult } n2 \mid n3 = n1) \rightarrow (\text{ADiv } a1 \mid a2) \mid \mid n3
where "a'||' n" := (aevalR a n) : type\_scope.
End AEVALR_DIVISION.
Module AEVALR_EXTENDED.
Inductive aexp : Type :=
    AAny: aexp
     ANum : nat \rightarrow aexp
     APlus : aexp \rightarrow aexp \rightarrow aexp
     AMinus : aexp \rightarrow aexp \rightarrow aexp
    AMult : aexp \rightarrow aexp \rightarrow aexp.
```

Again, extending **aeval** would be tricky (because evaluation is *not* a deterministic function from expressions to numbers), but extending **aevalR** is no problem:

```
Inductive aevalR : aexp \rightarrow nat \rightarrow Prop :=
```

```
\mid \mathsf{E}_{-}\mathsf{Any} : \forall (n:\mathsf{nat}),
           AAny \mid \mid n
   \mid \mathsf{E}_{-}\mathsf{ANum} : \forall (n:\mathsf{nat}),
           (ANum n) || n
   \mid \mathsf{E\_APlus} : \forall (a1 \ a2 : \mathsf{aexp}) (n1 \ n2 : \mathsf{nat}),
           (a1 \mid \mid n1) \rightarrow (a2 \mid \mid n2) \rightarrow (APlus \ a1 \ a2) \mid \mid (n1 + n2)
   \mid \mathsf{E\_AMinus} : \forall (a1 \ a2 : \mathsf{aexp}) (n1 \ n2 : \mathsf{nat}),
           (a1 \mid \mid n1) \rightarrow (a2 \mid \mid n2) \rightarrow (AMinus \ a1 \ a2) \mid \mid (n1 - n2)
   \mid \mathsf{E\_AMult} : \forall (a1 \ a2: \mathbf{aexp}) (n1 \ n2: \mathbf{nat}),
           (a1 \mid \mid n1) \rightarrow (a2 \mid \mid n2) \rightarrow (AMult \ a1 \ a2) \mid \mid (n1 \times n2)
where "a'||' n" := (aevalR a n) : type\_scope.
End AEVALR_EXTENDED.
```

#### **Expressions With Variables** 27.5

Let's turn our attention back to defining Imp. The next thing we need to do is to enrich our arithmetic and boolean expressions with variables. To keep things simple, we'll assume that all variables are global and that they only hold numbers.

#### 27.5.1 **Identifiers**

To begin, we'll need to formalize *identifiers* such as program variables. We could use strings for this – or, in a real compiler, fancier structures like pointers into a symbol table. But for simplicity let's just use natural numbers as identifiers.

(We hide this section in a module because these definitions are actually in SfLib, but we want to repeat them here so that we can explain them.)

Module ID.

We define a new inductive datatype ld so that we won't confuse identifiers and numbers. We use **sumbool** to define a computable equality operator on Id.

```
Inductive id : Type :=
  Id: nat \rightarrow id.
Theorem eq_id_dec : \forall id1 \ id2 : id, \{id1 = id2\} + \{id1 \neq id2\}.
Proof.
   intros id1 id2.
   destruct id1 as [n1]. destruct id2 as [n2].
   destruct (eq_nat_dec n1 n2) as [Heq \mid Hneq].
   Case "n1 = n2".
     left. rewrite Heq. reflexivity.
   Case "n1 <> n2".
     right. intros contra. inversion contra. apply Hneq. apply H0.
```

```
Defined.
```

#### 27.5.2 States

End ID.

A state represents the current values of all the variables at some point in the execution of a program. For simplicity (to avoid dealing with partial functions), we let the state be defined for all variables, even though any given program is only going to mention a finite number of them.

```
Definition state := \operatorname{id} \to \operatorname{nat}.

Definition empty_state : state := \operatorname{fun} _{-} \Rightarrow 0.

Definition update (st:\operatorname{state})\ (x:\operatorname{id})\ (n:\operatorname{nat}):\operatorname{state}:= \operatorname{fun}\ x' \Rightarrow \operatorname{if}\ \operatorname{eq}_{\operatorname{id}}\operatorname{dec}\ x\ x' \operatorname{then}\ n \operatorname{else}\ st\ x'.

For proofs involving states, we'll need several simple properties of update.

Exercise: \operatorname{1}\ \operatorname{star}\ (\operatorname{update}_{-\operatorname{eq}}) Theorem update_eq : \forall\ n\ x\ st, (\operatorname{update}\ st\ x\ n)\ x = n.

Proof.

Admitted.
```

```
Exercise: 1 star (update_neq) Theorem update_neq: \forall x2 \ x1 \ n \ st,
  x2 \neq x1 \rightarrow
  (update st \ x2 \ n) \ x1 = (st \ x1).
Proof.
   Admitted.
   Exercise: 1 star (update_example) Before starting to play with tactics, make sure you
understand exactly what the theorem is saying!
Theorem update_example : \forall (n:nat),
  (update empty_state (ld 2) n) (ld 3) = 0.
Proof.
   Admitted.
   state),
   (update (update st \ x2 \ n1) x2 \ n2) x1 = (update st \ x2 \ n2) x1.
Proof.
   Admitted.
   Exercise: 2 stars (update_same) Theorem update_same : \forall n1 \ x2 \ (st : state),
  st \ x1 = n1 \rightarrow
  (update st \ x1 \ n1) x2 = st \ x2.
Proof.
   Admitted.
   Exercise: 3 stars (update_permute) Theorem update_permute: \forall n1 \ n2 \ x1 \ x2 \ x3 \ st,
  x2 \neq x1 \rightarrow
  (update (update st \ x2 \ n1) \ x1 \ n2) \ x3 = (update (update st \ x1 \ n2) \ x2 \ n1) \ x3.
Proof.
   Admitted.
```

### 27.5.3 Syntax

We can add variables to the arithmetic expressions we had before by simply adding one more constructor:

```
Inductive aexp : Type :=
```

```
 | \ \mathsf{ANum} : \mathsf{nat} \to \mathsf{aexp} \\ | \ \mathsf{Ald} : \mathsf{id} \to \mathsf{aexp} \\ | \ \mathsf{APlus} : \ \mathsf{aexp} \to \mathsf{aexp} \to \mathsf{aexp} \\ | \ \mathsf{AMinus} : \ \mathsf{aexp} \to \mathsf{aexp} \to \mathsf{aexp} \\ | \ \mathsf{AMult} : \ \mathsf{aexp} \to \mathsf{aexp} \to \mathsf{aexp} \\ | \ \mathsf{AMult} : \ \mathsf{aexp} \to \mathsf{aexp} \to \mathsf{aexp}. \\ | \ \mathsf{Tactic} \ \ \mathsf{Notation} \ \ "\mathsf{aexp\_cases}" \ \ \mathit{tactic}(\mathsf{first}) \ \ \mathit{ident}(c) := \\ \mathsf{first}; \\ | \ \mathit{Case\_aux} \ c \ "\mathsf{ANum}" \ | \ \mathit{Case\_aux} \ c \ "\mathsf{AId}" \ | \ \mathit{Case\_aux} \ c \ "\mathsf{APlus}" \\ | \ \mathit{Case\_aux} \ c \ "\mathsf{AMult}" \ | \ \mathit{Case\_aux} \ | \ \mathsf{Case\_aux} \
```

Defining a few variable names as notational shorthands will make examples easier to read:

```
Definition X : id := Id 0.
Definition Y : id := Id 1.
Definition Z : id := Id 2.
```

(This convention for naming program variables (X, Y, Z) clashes a bit with our earlier use of uppercase letters for types. Since we're not using polymorphism heavily in this part of the course, this overloading should not cause confusion.)

The definition of **bexp**s is the same as before (using the new **aexp**s):

```
Inductive bexp : Type :=
    | BTrue : bexp
    | BFalse : bexp
    | BEq : aexp → aexp → bexp
    | BLe : aexp → aexp → bexp
    | BNot : bexp → bexp
    | BAnd : bexp → bexp
    | BAnd : bexp → bexp → cases" tactic(first) ident(c) :=
    first;
    [ Case_aux c "BTrue" | Case_aux c "BFalse" | Case_aux c "BEq"
    | Case_aux c "BLe" | Case_aux c "BNot" | Case_aux c "BAnd" ].
```

#### 27.5.4 Evaluation

The arith and boolean evaluators can be extended to handle variables in the obvious way:

```
Fixpoint aeval (st: state) (a: aexp): nat:= match a with | ANum n \Rightarrow n | Ald x \Rightarrow st x | APlus a1 a2 \Rightarrow (aeval st a1) + (aeval st a2) | AMinus a1 a2 \Rightarrow (aeval st a1) - (aeval st a2) | AMult a1 a2 \Rightarrow (aeval st a1) \times (aeval st a2) end.
```

```
Fixpoint beval (st : state) (b : bexp) : bool :=
  match b with
    BTrue \Rightarrow true
    BFalse \Rightarrow false
    BEg a1 a2 \Rightarrow beg_nat (aeval st a1) (aeval st a2)
   BLe a1 a2 \Rightarrow ble_nat (aeval st a1) (aeval st a2)
   BNot b1 \Rightarrow \text{negb} (beval st \ b1)
   BAnd b1 b2 \Rightarrow andb (beval st b1) (beval st b2)
  end.
Example aexp1:
  aeval (update empty_state X 5)
          (APlus (ANum 3) (AMult (Ald X) (ANum 2)))
  = 13.
Proof. reflexivity. Qed.
Example bexp1:
  beval (update empty_state X 5)
          (BAnd BTrue (BNot (BLe (Ald X) (ANum 4))))
  = true.
Proof. reflexivity. Qed.
```

## 27.6 Commands

Now we are ready define the syntax and behavior of Imp *commands* (often called *state-ments*).

# 27.6.1 Syntax

Informally, commands c are described by the following BNF grammar:  $c := SKIP \mid x := a \mid c$ ;  $c \mid WHILE$  b DO c END  $\mid$  IFB b THEN c ELSE c FI For example, here's the factorial function in Imp. Z := X; Y := 1; WHILE not (Z = 0) DO Y := Y \* Z; Z := Z - 1 END When this command terminates, the variable Y will contain the factorial of the initial value of X.

Here is the formal definition of the syntax of commands:

```
Inductive com: Type:=

| CSkip: com

| CAss: id \rightarrow aexp \rightarrow com

| CSeq: com \rightarrow com \rightarrow com

| CIf: bexp \rightarrow com \rightarrow com \rightarrow com

| CWhile: bexp \rightarrow com \rightarrow com

| Tactic Notation "com_cases" tactic(first) ident(c) := first;
```

```
[ Case\_aux \ c "SKIP" | Case\_aux \ c "::=" | Case\_aux \ c ";;" | Case\_aux \ c "IFB" | Case\_aux \ c "WHILE" ].
```

As usual, we can use a few Notation declarations to make things more readable. We need to be a bit careful to avoid conflicts with Coq's built-in notations, so we'll keep this light – in particular, we won't introduce any notations for aexps and bexps to avoid confusion with the numerical and boolean operators we've already defined. We use the keyword IFB for conditionals instead of IF, for similar reasons.

```
Notation "'SKIP'" :=
  CSkip.
Notation "x '::=' a" :=
  (CAss x a) (at level 60).
Notation "c1;; c2" :=
  (CSeq c1 c2) (at level 80, right associativity).
Notation "'WHILE' b 'DO' c 'END'" :=
  (CWhile b c) (at level 80, right associativity).
Notation "'IFB' c1 'THEN' c2 'ELSE' c3 'FI'" :=
  (Clf c1 c2 c3) (at level 80, right associativity).
   For example, here is the factorial function again, written as a formal definition to Coq:
Definition fact_in_cog : com :=
  Z ::= Ald X;;
  Y ::= ANum 1;;
  WHILE BNot (BEq (Ald Z) (ANum 0)) DO
    Y ::= AMult (Ald Y) (Ald Z);;
    Z ::= AMinus (Ald Z) (ANum 1)
  END.
```

## 27.6.2 Examples

```
Assignment:
```

```
Definition plus2 : com :=
   X ::= (APlus (Ald X) (ANum 2)).
Definition XtimesYinZ : com :=
   Z ::= (AMult (Ald X) (Ald Y)).
Definition subtract_slowly_body : com :=
   Z ::= AMinus (Ald Z) (ANum 1) ;;
   X ::= AMinus (Ald X) (ANum 1).
   Loops:
Definition subtract_slowly : com :=
   WHILE BNot (BEq (Ald X) (ANum 0)) DO   subtract_slowly_body
```

```
END.
Definition subtract_3_from_5_slowly : com :=
   X ::= ANum 3 ;;
   Z ::= ANum 5 ;;
   subtract_slowly.
   An infinite loop:
Definition loop : com :=
   WHILE BTrue DO
   SKIP
   END.
```

## 27.7 Evaluation

Next we need to define what it means to evaluate an Imp command. The fact that WHILE loops don't necessarily terminate makes defining an evaluation function tricky...

## 27.7.1 Evaluation as a Function (Failed Attempt)

Here's an attempt at defining an evaluation function for commands, omitting the WHILE case.

```
Fixpoint ceval_fun_no_while (st : state) (c : com) : state :=
  {\tt match}\ c\ {\tt with}
     \mid SKIP \Rightarrow
           st
     \mid x ::= a1 \Rightarrow
           update st \ x (aeval st \ a1)
     |c1;;c2\Rightarrow
           let st' := \text{ceval\_fun\_no\_while } st \ c1 \ \text{in}
           ceval_fun_no_while st' c2
      | IFB b THEN c1 ELSE c2 FI \Rightarrow
           if (beval st b)
              then ceval_fun_no_while st c1
              else ceval_fun_no_while st\ c2
      WHILE b DO c END \Rightarrow
           st
  end.
```

In a traditional functional programming language like ML or Haskell we could write the WHILE case as follows:

```
Fixpoint ceval_fun (st : state) (c : com) : state :=
  match c with
```

```
...
| WHILE b DO c END =>
    if (beval st b1)
        then ceval_fun st (c1; WHILE b DO c END)
        else st
end.
```

Coq doesn't accept such a definition ("Error: Cannot guess decreasing argument of fix") because the function we want to define is not guaranteed to terminate. Indeed, it doesn't always terminate: for example, the full version of the *ceval\_fun* function applied to the loop program above would never terminate. Since Coq is not just a functional programming language, but also a consistent logic, any potentially non-terminating function needs to be rejected. Here is an (invalid!) Coq program showing what would go wrong if Coq allowed non-terminating recursive functions:

```
Fixpoint loop_false (n : nat) : False := loop_false n.
```

That is, propositions like **False** would become provable (e.g. *loop\_false* 0 would be a proof of **False**), which would be a disaster for Coq's logical consistency.

Thus, because it doesn't terminate on all inputs, the full version of *ceval\_fun* cannot be written in Coq – at least not without additional tricks (see chapter ImpCEvalFun if curious).

#### 27.7.2 Evaluation as a Relation

Here's a better way: we define **ceval** as a *relation* rather than a function - i.e., we define it in Prop instead of Type, as we did for **aevalR** above.

This is an important change. Besides freeing us from the awkward workarounds that would be needed to define evaluation as a function, it gives us a lot more flexibility in the definition. For example, if we added concurrency features to the language, we'd want the definition of evaluation to be non-deterministic – i.e., not only would it not be total, it would not even be a partial function!

We'll use the notation c / st || st' for our **ceval** relation: c / st || st' means that executing program c in a starting state st results in an ending state st'. This can be pronounced "c takes state st to st".

```
 \begin{split} &(E\_Skip) \; SKIP \; / \; st \; || \; st \\ & \; aeval \; st \; a1 = n \end{split}   \begin{split} &(E\_Ass) \; x := a1 \; / \; st \; || \; (update \; st \; x \; n) \\ &c1 \; / \; st \; || \; st' \; c2 \; / \; st' \; || \; st'' \\ &(E\_Seq) \; c1;;c2 \; / \; st \; || \; st'' \\ &beval \; st \; b1 = true \; c1 \; / \; st \; || \; st' \end{split}
```

```
(E_IfTrue) IF b1 THEN c1 ELSE c2 FI / st || st'
    beval st b1 = false c2 / st || st'
(E_IfFalse) IF b1 THEN c1 ELSE c2 FI / st || st'
    beval st b1 = false
(E_WhileEnd) WHILE b DO c END / st || st
    beval st b1 = true c / st || st' WHILE b DO c END / st' || st"
(E_WhileLoop) WHILE b DO c END / st || st"
    Here is the formal definition. (Make sure you understand how it corresponds to the
inference rules.)
Reserved Notation "c1 '/' st '||' st'" (at level 40, st at level 39).
Inductive ceval: com \rightarrow state \rightarrow state \rightarrow Prop :=
   \mid \mathsf{E}_{\mathsf{S}}\mathsf{kip} : \forall st,
         SKIP / st || st
   \mid \mathsf{E}_{-}\mathsf{Ass} : \forall \ st \ a1 \ n \ x,
         aeval st a1 = n \rightarrow
         (x := a1) / st \mid\mid (update st x n)
  \mid \mathsf{E}_{-}\mathsf{Seq} : \forall \ c1 \ c2 \ st \ st' \ st'',
         c1 / st \mid \mid st' \rightarrow
         c2 / st' \mid \mid st'' \rightarrow
         (c1;; c2) / st || st"
   \mid \mathsf{E_{-}lfTrue} : \forall st st' b c1 c2,
         beval st b = true \rightarrow
         c1 / st \mid \mid st' \rightarrow
         (IFB b THEN c1 ELSE c2 FI) / st || st
   \mid \mathsf{E_IfFalse} : \forall st st' b c1 c2,
         beval st b = false \rightarrow
         c2 / st \mid \mid st' \rightarrow
         (IFB b THEN c1 ELSE c2 FI) / st || st
   \mid \mathsf{E}_{-}\mathsf{WhileEnd} : \forall \ b \ st \ c,
         beval st b = false \rightarrow
         (WHILE b DO c END) / st || st
   \mid \mathsf{E}_{\mathsf{-}}\mathsf{WhileLoop} : \forall st \ st' \ st'' \ b \ c,
         beval st b = true \rightarrow
         c / st \mid \mid st' \rightarrow
         (WHILE b DO c END) / st' \mid \mid st'' \rightarrow
         (WHILE b DO c END) / st || st''
   where "c1 '/' st '||' st'" := (ceval c1 \ st \ st').
```

Tactic Notation "ceval\_cases" tactic(first) ident(c) :=

```
first:
[ Case_aux c "E_Skip" | Case_aux c "E_Ass" | Case_aux c "E_Seq"
 Case_aux c "E_IfTrue" | Case_aux c "E_IfFalse"
Case_aux c "E_WhileEnd" | Case_aux c "E_WhileLoop" ].
```

The cost of defining evaluation as a relation instead of a function is that we now need to construct proofs that some program evaluates to some result state, rather than just letting

```
Cog's computation mechanism do it for us.
Example ceval_example1:
    (X ::= ANum 2;;
     IFB BLe (Ald X) (ANum 1)
       THEN Y ::= ANum 3
       ELSE Z ::= ANum 4
     FI)
   / empty_state
   | | (update (update empty_state X 2) Z 4).
Proof.
  apply E_Seq with (update empty_state X 2).
  Case "assignment command".
    apply E_Ass. reflexivity.
  Case "if command".
    apply E_lfFalse.
      reflexivity.
      apply E_Ass. reflexivity. Qed.
Exercise: 2 stars (ceval_example2) Example ceval_example2:
    (X ::= ANum 0;; Y ::= ANum 1;; Z ::= ANum 2) / empty_state | |
    (update (update empty_state X \ 0) \ Y \ 1) \ Z \ 2).
Proof.
   Admitted.
   Exercise: 3 stars, advanced (pup_to_n) Write an Imp program that sums the numbers
from 1 to X (inclusive: 1+2+...+X) in the variable Y. Prove that this program executes
as intended for X = 2 (this latter part is trickier than you might expect).
Definition pup_to_n : com :=
  admit.
Theorem pup_to_2_ceval:
  pup_to_n / (update empty_state X 2) ||
    update (update (update (update (update empty_state
      X 2) Y 0) Y 2) X 1) Y 3) X 0.
```

Proof.

#### 27.7.3 Determinism of Evaluation

Changing from a computational to a relational definition of evaluation is a good move because it allows us to escape from the artificial requirement (imposed by Coq's restrictions on Fixpoint definitions) that evaluation should be a total function. But it also raises a question: Is the second definition of evaluation actually a partial function? That is, is it possible that, beginning from the same state st, we could evaluate some command c in different ways to reach two different output states st and st?

In fact, this cannot happen: **ceval** is a partial function. Here's the proof:

```
Theorem ceval_deterministic: \forall c \ st \ st1 \ st2,
      c / st \mid \mid st1 \rightarrow
      c / st \mid \mid st2 \rightarrow
     st1 = st2.
Proof.
  intros c st st1 st2 E1 E2.
  generalize dependent st2.
  ceval_cases (induction E1) Case;
            intros st2 E2; inversion E2; subst.
  Case "E_Skip". reflexivity.
  Case "E_Ass". reflexivity.
  Case "E_Seq".
    assert (st' = st'\theta) as EQ1.
       SCase "Proof of assertion". apply IHE1_1; assumption.
    subst st'0.
    apply IHE1_2. assumption.
  Case "E_IfTrue".
    SCase "b1 evaluates to true".
       apply IHE1. assumption.
    SCase "b1 evaluates to false (contradiction)".
      rewrite H in H5. inversion H5.
  Case "E_IfFalse".
    SCase "b1 evaluates to true (contradiction)".
      rewrite H in H5. inversion H5.
    SCase "b1 evaluates to false".
       apply IHE1. assumption.
  Case "E_WhileEnd".
    SCase "b1 evaluates to false".
      reflexivity.
    SCase "b1 evaluates to true (contradiction)".
```

```
rewrite H in H2. inversion H2.

Case "E_WhileLoop".

SCase "b1 evaluates to false (contradiction)".

rewrite H in H4. inversion H4.

SCase "b1 evaluates to true".

assert (st' = st'0) as EQ1.

SSCase "Proof of assertion". apply IHE1_1; assumption. subst st'0.

apply IHE1_2. assumption. Qed.
```

# 27.8 Reasoning About Imp Programs

We'll get much deeper into systematic techniques for reasoning about Imp programs in the following chapters, but we can do quite a bit just working with the bare definitions.

```
Theorem plus2_spec : \forall st \ n \ st',
  st X = n \rightarrow
  plus2 / st \mid \mid st' \rightarrow
  st' X = n + 2.
Proof.
  intros st n st' HX Heval.
  inversion Heval. subst. clear Heval. simpl.
  apply update_eq. Qed.
Exercise: 3 stars (XtimesYinZ_spec) State and prove a specification of XtimesYinZ.
   Exercise: 3 stars (loop_never_stops) Theorem loop_never_stops: \forall st st',
  \sim (loop / st \mid \mid st').
Proof.
  intros st st' contra. unfold loop in contra.
  remember (WHILE BTrue DO SKIP END) as loopdef eqn: Hegloopdef.
    Admitted.
   Exercise: 3 stars (no_whilesR) Consider the definition of the no_whiles property be-
low:
Fixpoint no_whiles (c : \mathbf{com}) : \mathbf{bool} :=
  {\tt match}\ c\ {\tt with}
   SKIP \Rightarrow true
  | \_ ::= \_ \Rightarrow \mathsf{true}
```

```
| c1 ;; c2 \Rightarrow \text{andb} (no_whiles c1) (no_whiles c2)
| IFB _ THEN ct ELSE cf FI \Rightarrow andb (no_whiles ct) (no_whiles cf)
| WHILE _ DO _ END \Rightarrow false
end.
```

This property yields true just on programs that have no while loops. Using Inductive, write a property no\_whilesR such that no\_whilesR c is provable exactly when c is a program with no while loops. Then prove its equivalence with no\_whiles.

```
Inductive no\_whilesR: com \rightarrow Prop :=
```

```
Theorem no_whiles_eqv: \forall c, \text{ no\_whiles } c = \text{true} \leftrightarrow \text{no\_whilesR} c. Proof. Admitted.
```

Exercise: 4 stars (no\_whiles\_terminating) Imp programs that don't involve while loops always terminate. State and prove a theorem that says this. (Use either no\_whiles or no\_whilesR, as you prefer.)

## 27.9 Additional Exercises

Exercise: 3 stars (stack\_compiler) HP Calculators, programming languages like Forth and Postscript, and abstract machines like the Java Virtual Machine all evaluate arithmetic expressions using a stack. For instance, the expression

```
(2*3)+(3*(4-2))
```

would be entered as

```
2 3 * 3 4 2 - * +
```

and evaluated like this:

```
[2, 3, 6] | * -
[6, 6] | +
[12]
```

The task of this exercise is to write a small compiler that translates **aexp**s into stack machine instructions.

The instruction set for our stack language will consist of the following instructions:

- SPush n: Push the number n on the stack.
- SLoad x: Load the identifier x from the store and push it on the stack
- SPlus: Pop the two top numbers from the stack, add them, and push the result onto the stack.
- SMinus: Similar, but subtract.
- SMult: Similar, but multiply.

```
Inductive sinstr : Type :=
| SPush : nat → sinstr
| SLoad : id → sinstr
| SPlus : sinstr
| SMinus : sinstr
| SMult : sinstr.
```

Write a function to evaluate programs in the stack language. It takes as input a state, a stack represented as a list of numbers (top stack item is the head of the list), and a program represented as a list of instructions, and returns the stack after executing the program. Test your function on the examples below.

Note that the specification leaves unspecified what to do when encountering an SPlus, SMinus, or SMult instruction if the stack contains less than two elements. In a sense, it is immaterial what we do, since our compiler will never emit such a malformed program.

```
[SPush 4; SLoad X; SMult; SPlus] = [15; 4].

Admitted.
```

Next, write a function which compiles an **aexp** into a stack machine program. The effect of running the program should be the same as pushing the value of the expression on the stack.

```
Fixpoint s_compile (e : aexp) : list sinstr := admit.
```

After you've defined s\_compile, uncomment the following to test that it works.

Exercise: 3 stars, advanced (stack\_compiler\_correct) The task of this exercise is to prove the correctness of the calculator implemented in the previous exercise. Remember that the specification left unspecified what to do when encountering an SPlus, SMinus, or SMult instruction if the stack contains less than two elements. (In order to make your correctness proof easier you may find it useful to go back and change your implementation!)

Prove the following theorem, stating that the *compile* function behaves correctly. You will need to start by stating a more general lemma to get a usable induction hypothesis; the main theorem will then be a simple corollary of this lemma.

```
Theorem s_compile_correct : \forall (st : state) (e : aexp), s_execute st [] (s_compile e) = [ aeval st e ]. Proof.

Admitted.
```

Exercise: 5 stars, advanced (break\_imp) Module BREAKIMP.

Imperative languages such as C or Java often have a break or similar statement for interrupting the execution of loops. In this exercise we will consider how to add break to Imp.

First, we need to enrich the language of commands with an additional case.

```
Inductive com : Type :=  | \ \mathsf{CSkip} : \mathbf{com} \\ | \ \mathsf{CBreak} : \mathbf{com} \\ | \ \mathsf{CAss} : \mathbf{id} \to \mathbf{aexp} \to \mathbf{com} \\ | \ \mathsf{CSeq} : \mathbf{com} \to \mathbf{com} \to \mathbf{com} \\ | \ \mathsf{CIf} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com} \to \mathbf{com} \\ | \ \mathsf{CWhile} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com} \to \mathbf{com} \\ | \ \mathsf{CWhile} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com} .  Tactic Notation "com_cases" tactic(\mathtt{first}) \ ident(c) := \mathtt{first}; \\ | \ \mathsf{Case\_aux} \ c \ "\mathsf{SKIP}" \ | \ \mathsf{Case\_aux} \ c \ "\mathsf{BREAK}" \ | \ \mathsf{Case\_aux} \ c \ "::=" \ | \ \mathsf{Case\_aux} \ c \ ";"
```

```
 | \textit{Case\_aux} \ c \ "IFB" \ | \ \textit{Case\_aux} \ c \ "WHILE" \ ].  Notation "'SKIP'" := CSkip.  
Notation "'BREAK'" := CBreak.  
Notation "x '::=' a" := (CAss x a) (at level 60).  
Notation "c1 ; c2" := (CSeq c1 c2) (at level 80, right associativity).  
Notation "'WHILE' b 'DO' c 'END'" := (CWhile b c) (at level 80, right associativity).  
Notation "'IFB' c1 'THEN' c2 'ELSE' c3 'FI'" := (Clf c1 c2 c3) (at level 80, right associativity).
```

Next, we need to define the behavior of BREAK. Informally, whenever BREAK is executed in a sequence of commands, it stops the execution of that sequence and signals that the innermost enclosing loop (if any) should terminate. If there aren't any enclosing loops, then the whole program simply terminates. The final state should be the same as the one in which the BREAK statement was executed.

One important point is what to do when there are multiple loops enclosing a given BREAK. In those cases, BREAK should only terminate the innermost loop where it occurs. Thus, after executing the following piece of code... X := 0; Y := 1; WHILE 0 <> Y DO WHILE TRUE DO BREAK END; X := 1; Y := Y - 1 END ... the value of X should be 1, and not 0.

One way of expressing this behavior is to add another parameter to the evaluation relation that specifies whether evaluation of a command executes a BREAK statement:

```
Inductive status : Type :=  | \mbox{ SContinue : status } | \mbox{ SBreak : status.}  Reserved Notation "c1 '/' st '||' s '/' st'"  (\mbox{at level } 40, \mbox{ $st$, $s$ at level } 39).
```

Intuitively,  $c / st \parallel s / st'$  means that, if c is started in state st, then it terminates in state st' and either signals that any surrounding loop (or the whole program) should exit immediately ( $s = \mathsf{SBreak}$ ) or that execution should continue normally ( $s = \mathsf{SContinue}$ ).

The definition of the "c / st || s / st" relation is very similar to the one we gave above for the regular evaluation relation (c / st || s / st) – we just need to handle the termination signals appropriately:

- If the command is *SKIP*, then the state doesn't change, and execution of any enclosing loop can continue normally.
- If the command is BREAK, the state stays unchanged, but we signal a SBreak.

- If the command is an assignment, then we update the binding for that variable in the state accordingly and signal that execution can continue normally.
- If the command is of the form *IF* b *THEN* c1 *ELSE* c2 *FI*, then the state is updated as in the original semantics of Imp, except that we also propagate the signal from the execution of whichever branch was taken.
- If the command is a sequence c1; c2, we first execute c1. If this yields a SBreak, we skip the execution of c2 and propagate the SBreak signal to the surrounding context; the resulting state should be the same as the one obtained by executing c1 alone. Otherwise, we execute c2 on the state obtained after executing c1, and propagate the signal that was generated there.
- Finally, for a loop of the form WHILE b DO c END, the semantics is almost the same as before. The only difference is that, when b evaluates to true, we execute c and check the signal that it raises. If that signal is SContinue, then the execution proceeds as in the original semantics. Otherwise, we stop the execution of the loop, and the resulting state is the same as the one resulting from the execution of the current iteration. In either case, since BREAK only terminates the innermost loop, WHILE signals SContinue.

Based on the above description, complete the definition of the **ceval** relation.

```
Inductive ceval: com \rightarrow state \rightarrow status \rightarrow state \rightarrow Prop :=
   \mid \mathsf{E\_Skip} : \forall st,
        \mathsf{CSkip} \ / \ st \ | \ | \ \mathsf{SContinue} \ / \ st
   where "c1',' st'||' s',' st'" := (ceval c1 st s st').
Tactic Notation "ceval_cases" tactic(first) ident(c) :=
   first:
   [ Case\_aux \ c "E_Skip"
  ].
    Now the following properties of your definition of ceval:
Theorem break_ignore : \forall c \ st \ st' \ s,
       (BREAK; c) / st | | s / st' \rightarrow
       st = st'.
Proof.
    Admitted.
Theorem while_continue: \forall b \ c \ st \ st' \ s,
   (WHILE b DO c END) / st \mid \mid s / st' \rightarrow
   s = SContinue.
```

```
Proof.
    Admitted.
Theorem while_stops_on_break : \forall b \ c \ st \ st',
   beval st b = true \rightarrow
   c / st | | SBreak / st' \rightarrow
   (WHILE b DO c END) / st || SContinue / st'.
Proof.
    Admitted.
Theorem while_break_true : \forall b \ c \ st \ st',
   (WHILE b DO c END) / st || SContinue / st' \rightarrow
   beval st' b = true \rightarrow
   \exists st'', c / st'' \mid \mid \mathsf{SBreak} / st'.
Proof.
    Admitted.
Theorem ceval_deterministic: \forall (c:\mathbf{com}) \ st \ st1 \ st2 \ s1 \ s2,
       c / st \mid \mid s1 / st1 \rightarrow
       c / st \mid \mid s2 / st2 \rightarrow
       st1 = st2 \land s1 = s2.
Proof.
    Admitted.
End BreakImp.
```

**Exercise:** 3 stars, optional (short\_circuit) Most modern programming languages use a "short-circuit" evaluation rule for boolean and: to evaluate BAnd b1 b2, first evaluate b1. If it evaluates to false, then the entire BAnd expression evaluates to false immediately, without evaluating b2. Otherwise, b2 is evaluated to determine the result of the BAnd expression.

Write an alternate version of beval that performs short-circuit evaluation of BAnd in this manner, and prove that it is equivalent to beval.

Exercise: 4 stars, optional (add\_for\_loop) Add C-style for loops to the language of commands, update the **ceval** definition to define the semantics of for loops, and add cases for for loops as needed so that all the proofs in this file are accepted by Coq.

A for loop should be parameterized by (a) a statement executed initially, (b) a test that is run on each iteration of the loop to determine whether the loop should continue, (c) a statement executed at the end of each loop iteration, and (d) a statement that makes up the body of the loop. (You don't need to worry about making up a concrete Notation for for loops, but feel free to play with this too if you like.)

# Chapter 28

# Library SfLib

# 28.1 SfLib: Software Foundations Library

Here we collect together several useful definitions and theorems from Basics.v, List.v, Poly.v, Ind.v, and Logic.v that are not already in the Coq standard library. From now on we can Import or Export this file, instead of cluttering our environment with all the examples and false starts in those files.

# 28.2 From the Coq Standard Library

```
Require Omega. Require Export Bool.

# Chapter 29

# Library MoreInd

## 29.1 MoreInd: More on Induction

Require Export ProofObjects.

# 29.2 Induction Principles

This is a good point to pause and take a deeper look at induction principles.

Every time we declare a new Inductive datatype, Coq automatically generates and proves an *induction principle* for this type.

The induction principle for a type t is called  $t_{-}ind$ . Here is the one for natural numbers:

Check nat\_ind.

The induction tactic is a straightforward wrapper that, at its core, simply performs apply  $t\_ind$ . To see this more clearly, let's experiment a little with using apply  $nat\_ind$  directly, instead of the induction tactic, to carry out some proofs. Here, for example, is an alternate proof of a theorem that we saw in the Basics chapter.

```
Theorem mult_0_r': \forall n:nat, n \times 0 = 0.

Proof.

apply nat_ind.

Case "O". reflexivity.

Case "S". simpl. intros n IHn. rewrite \rightarrow IHn. reflexivity. Qed.
```

This proof is basically the same as the earlier one, but a few minor differences are worth noting. First, in the induction step of the proof (the "S" case), we have to do a little bookkeeping manually (the intros) that induction does automatically.

Second, we do not introduce n into the context before applying nat\_ind – the conclusion of nat\_ind is a quantified formula, and apply needs this conclusion to exactly match the

shape of the goal state, including the quantifier. The induction tactic works either with a variable in the context or a quantified variable in the goal.

Third, the apply tactic automatically chooses variable names for us (in the second subgoal, here), whereas induction lets us specify (with the as... clause) what names should be used. The automatic choice is actually a little unfortunate, since it re-uses the name n for a variable that is different from the n in the original theorem. This is why the Case annotation is just S – if we tried to write it out in the more explicit form that we've been using for most proofs, we'd have to write n = S n, which doesn't make a lot of sense! All of these conveniences make induction nicer to use in practice than applying induction principles like nat\_ind directly. But it is important to realize that, modulo this little bit of bookkeeping, applying nat\_ind is what we are really doing.

Exercise: 2 stars, optional (plus\_one\_r') Complete this proof as we did mult\_0\_r' above, without using the induction tactic.

```
Theorem plus_one_r' : \forall n:nat,

n + 1 = S n.

Proof.

Admitted.
```

Coq generates induction principles for every datatype defined with Inductive, including those that aren't recursive. (Although we don't need induction to prove properties of non-recursive datatypes, the idea of an induction principle still makes sense for them: it gives a way to prove that a property holds for all values of the type.)

These generated principles follow a similar pattern. If we define a type t with constructors c1 ... cn, Coq generates a theorem with this shape: t\_ind : forall P : t -> Prop, ... case for c1 ... -> ... case for c2 ... -> ... ... case for cn ... -> forall n : t, P n The specific shape of each case depends on the arguments to the corresponding constructor. Before trying to write down a general rule, let's look at some more examples. First, an example where the constructors take no arguments:

```
Inductive yesno : Type :=
  | yes : yesno
  | no : yesno.
Check yesno_ind.
```

Exercise: 1 star, optional (rgb) Write out the induction principle that Coq will generate for the following datatype. Write down your answer on paper or type it into a comment, and then compare it with what Coq prints.

```
Inductive rgb : Type :=
  | red : rgb
  | green : rgb
  | blue : rgb.
```

Check rgb\_ind.

Here's another example, this time with one of the constructors taking some arguments.

```
Inductive natlist : Type :=
    | nnil : natlist
    | ncons : nat → natlist → natlist.
```

Check natlist\_ind.

Exercise: 1 star, optional (natlist1) Suppose we had written the above definition a little differently:

```
\label{eq:inductive natlist1} \begin{split} & | \  \, \text{nnil1}: \  \, \text{natlist1} \\ & | \  \, \text{nsnoc1}: \  \, \text{natlist1} \rightarrow \text{nat} \rightarrow \text{natlist1}. \end{split}
```

Now what will the induction principle look like?  $\square$  From these examples, we can extract this general rule:

- The type declaration gives several constructors; each corresponds to one clause of the induction principle.
- Each constructor c takes argument types a1...an.
- Each ai can be either t (the datatype we are defining) or some other type s.
- The corresponding case of the induction principle says (in English):
  - "for all values x1...xn of types a1...an, if P holds for each of the inductive arguments (each xi of type t), then P holds for c x1 ... xn".

Exercise: 1 star, optional (byntree\_ind) Write out the induction principle that Coq will generate for the following datatype. Write down your answer on paper or type it into a comment, and then compare it with what Coq prints.

```
Inductive byntree : Type :=
  | bempty : byntree
  | bleaf : yesno → byntree
  | nbranch : yesno → byntree → byntree → byntree.
```

**Exercise:** 1 star, optional (ex\_set) Here is an induction principle for an inductively defined set. ExSet\_ind: forall P: ExSet -> Prop, (forall b: bool, P (con1 b)) -> (forall (n: nat) (e: ExSet), Pe -> P (con2 ne)) -> forall e: ExSet, Pe Give an Inductive definition of ExSet:

```
Inductive ExSet : Type :=
```

What about polymorphic datatypes?

The inductive definition of polymorphic lists Inductive list (X:Type): Type := | nil : list $X \mid cons : X \rightarrow list X \rightarrow list X$ , is very similar to that of **natlist**. The main difference is that, here, the whole definition is parameterized on a set X: that is, we are defining a family of inductive types list X, one for each X. (Note that, wherever list appears in the body of the declaration, it is always applied to the parameter X.) The induction principle is likewise parameterized on X: list\_ind : forall (X : Type) (P : list X -> Prop), P  $\square$  -> (forall (x : X)  $(l: list X), Pl \rightarrow P(x:: l)) \rightarrow forall l: list X, Pl Note the wording here (and, accordingly,$ the form of list\_ind): The whole induction principle is parameterized on X. That is, list\_ind can be thought of as a polymorphic function that, when applied to a type X, gives us back an induction principle specialized to the type **list** X.

Exercise: 1 star, optional (tree) Write out the induction principle that Coq will generate for the following datatype. Compare your answer with what Coq prints.

```
Inductive tree (X:Type): Type :=
    leaf : X \to \mathbf{tree} \ X
   node : tree X \to \mathsf{tree}\ X \to \mathsf{tree}\ X.
Check tree_ind.
```

Exercise: 1 star, optional (mytype) Find an inductive definition that gives rise to the following induction principle: mytype\_ind: forall (X: Type) (P: mytype X -> Prop), (forall x: X, P (constr1 X x)) -> (forall n: nat, P (constr2 X n)) -> (forall m: mytype X, P m -> forall n : nat, P (constr3 X m n)) -> forall m : mytype X, P m  $\square$ 

Exercise: 1 star, optional (foo) Find an inductive definition that gives rise to the following induction principle: foo\_ind: forall (X Y: Type) (P: foo X Y -> Prop), (forall x : X, P (bar X Y x)) -> (forall y : Y, P (baz X Y y)) -> (forall f1 : nat -> foo X Y, (forall  $n: nat, P(f1 n)) \rightarrow P(guux X Y f1)) \rightarrow forall f2: foo X Y, P f2 \square$ 

Exercise: 1 star, optional (foo') Consider the following inductive definition:

```
Inductive foo' (X:Type): Type :=
   \mid C1 : list X \rightarrow foo' X \rightarrow foo' X
  \mid C2 : foo' X.
```

What induction principle will Coq generate for **foo'**? Fill in the blanks, then check your answer with Coq.) foo'\_ind: forall (X: Type) (P: foo' X-> Prop), (forall (l: list X) (f: foo' 

```
-> forall f : foo' X, ______
```

## 29.2.1 Induction Hypotheses

Where does the phrase "induction hypothesis" fit into this story?

The induction principle for numbers for all  $P: nat -> Prop, P 0 -> (for all n: nat, P n -> P (S n)) -> for all n: nat, P n is a generic statement that holds for all propositions P (strictly speaking, for all families of propositions P indexed by a number n). Each time we use this principle, we are choosing P to be a particular expression of type <math>nat \rightarrow Prop$ .

We can make the proof more explicit by giving this expression a name. For example, instead of stating the theorem  $mult_0_r$  as " $\forall$  n, n × 0 = 0," we can write it as " $\forall$  n, P\_m0r n", where P\_m0r is defined as...

```
Definition P_m0r (n:nat) : Prop :=
    n × 0 = 0.
    ... or equivalently...

Definition P_m0r' : nat→Prop :=
    fun n ⇒ n × 0 = 0.
    Now when we do the proof it is easier to see where P_m0r appears.

Theorem mult_0_r'' : ∀ n:nat,
    P_m0r n.

Proof.
    apply nat_ind.
    Case "n = O". reflexivity.
    Case "n = S n'".
    intros n IHn.
    unfold P_m0r in IHn. unfold P_m0r. simpl. apply IHn. Qed.
```

This extra naming step isn't something that we'll do in normal proofs, but it is useful to do it explicitly for an example or two, because it allows us to see exactly what the induction hypothesis is. If we prove  $\forall$  n, P\_m0r n by induction on n (using either induction or apply nat\_ind), we see that the first subgoal requires us to prove P\_m0r 0 ("P holds for zero"), while the second subgoal requires us to prove  $\forall$  n', P\_m0r n'  $\rightarrow$  P\_m0r n' (S n') (that is "P holds of S n' if it holds of n'" or, more elegantly, "P is preserved by S"). The *induction hypothesis* is the premise of this latter implication – the assumption that P holds of n', which we are allowed to use in proving that P holds for S n'.

#### 29.2.2 More on the induction Tactic

The induction tactic actually does even more low-level bookkeeping for us than we discussed above.

Recall the informal statement of the induction principle for natural numbers:

- If P n is some proposition involving a natural number n, and we want to show that P holds for *all* numbers n, we can reason like this:
  - show that P O holds
  - show that, if P n' holds, then so does P (S n')
  - conclude that P n holds for all n.

So, when we begin a proof with intros n and then induction n, we are first telling Coq to consider a particular n (by introducing it into the context) and then telling it to prove something about all numbers (by using induction).

What Coq actually does in this situation, internally, is to "re-generalize" the variable we perform induction on. For example, in our original proof that plus is associative...

```
Theorem plus_assoc' : \forall n \ m \ p : nat,
  n + (m + p) = (n + m) + p.
Proof.
  intros n m p.
  induction n as [\mid n'].
  Case "n = O". reflexivity.
  Case "n = S n".
     simpl. rewrite \rightarrow IHn'. reflexivity. Qed.
   It also works to apply induction to a variable that is quantified in the goal.
Theorem plus_comm': \forall n \ m : nat,
  n + m = m + n.
Proof.
  induction n as [\mid n'].
  Case "n = O". intros m. rewrite \rightarrow plus_0_r. reflexivity.
  Case "n = S n'". intros m. simpl. rewrite \rightarrow IHn'.
     rewrite \leftarrow plus\_n\_Sm. reflexivity. Qed.
```

Note that induction n leaves m still bound in the goal – i.e., what we are proving inductively is a statement beginning with  $\forall m$ .

If we do induction on a variable that is quantified in the goal *after* some other quantifiers, the induction tactic will automatically introduce the variables bound by these quantifiers into the context.

```
Theorem plus_comm": \forall \ n \ m: \mathsf{nat}, n+m=m+n.

Proof.

induction m as [|\ m'].

Case \ "m = O". \ simpl. \ rewrite \to \mathsf{plus}_0\_r. \ reflexivity.

Case \ "m = S \ m'". \ simpl. \ rewrite \leftarrow \mathit{IHm'}.

rewrite \leftarrow \mathit{plus}\_n\_Sm. \ reflexivity. \ Qed.
```

Exercise: 1 star, optional (plus\_explicit\_prop) Rewrite both plus\_assoc' and plus\_comm' and their proofs in the same style as mult\_0\_r'' above – that is, for each theorem, give an explicit Definition of the proposition being proved by induction, and state the theorem and proof in terms of this defined proposition.

## 29.2.3 Generalizing Inductions.

One potentially confusing feature of the induction tactic is that it happily lets you try to set up an induction over a term that isn't sufficiently general. The net effect of this will be do lose information (much as destruct can do), and leave you unable to complete the proof. Here's an example:

```
Lemma one_not_beautiful_FAILED: \neg beautiful 1. Proof. intro H. induction H. Abort.
```

The problem is that induction over a Prop only works properly over completely general instances of the Prop, i.e. one in which all the arguments are free (unconstrained) variables. In this respect it behaves more like destruct than like inversion.

When you're tempted to do use induction like this, it is generally an indication that you need to be proving something more general. But in some cases, it suffices to pull out any concrete arguments into separate equations, like this:

```
Lemma one_not_beautiful: \forall n, n = 1 \rightarrow \neg beautiful n.
Proof.
 intros n E H.
  induction H as [| \ | \ | \ p \ q \ Hp \ IHp \ Hq \ IHq].
     Case "b_0".
       inversion E.
     Case "b_3".
       inversion E.
     Case "b_5".
       inversion E.
     Case "b_sum".
       destruct p as [|p'|].
       SCase "p = 0".
         destruct q as [|q'|].
         SSCase "q = 0".
            inversion E.
         SSCase "q = S q'".
            apply IHq. apply E.
```

```
SCase \ "p = S \ p"".
destruct \ q \ as \ [|q'].
SSCase \ "q = 0".
apply \ IHp. \ rewrite \ plus_0_r \ in \ E. \ apply \ E.
SSCase \ "q = S \ q"".
simpl \ in \ E. \ inversion \ E. \ destruct \ p'. \ inversion \ H0. \ inversion \ H0.
Qed.
```

There's a handy *remember* tactic that can generate the second proof state out of the original one.

```
Lemma one_not_beautiful': \neg beautiful 1. Proof.
intros H.
remember\ 1 as n\ eqn:E.
induction H.
Admitted.
```

# 29.3 Informal Proofs (Advanced)

Q: What is the relation between a formal proof of a proposition P and an informal proof of the same proposition P?

A: The latter should *teach* the reader how to produce the former.

Q: How much detail is needed??

Unfortunately, There is no single right answer; rather, there is a range of choices.

At one end of the spectrum, we can essentially give the reader the whole formal proof (i.e., the informal proof amounts to just transcribing the formal one into words). This gives the reader the *ability* to reproduce the formal one for themselves, but it doesn't *teach* them anything.

At the other end of the spectrum, we can say "The theorem is true and you can figure out why for yourself if you think about it hard enough." This is also not a good teaching strategy, because usually writing the proof requires some deep insights into the thing we're proving, and most readers will give up before they rediscover all the same insights as we did.

In the middle is the golden mean – a proof that includes all of the essential insights (saving the reader the hard part of work that we went through to find the proof in the first place) and clear high-level suggestions for the more routine parts to save the reader from spending too much time reconstructing these parts (e.g., what the IH says and what must be shown in each case of an inductive proof), but not so much detail that the main ideas are obscured.

Another key point: if we're comparing a formal proof of a proposition P and an informal proof of P, the proposition P doesn't change. That is, formal and informal proofs are talking about the same world and they must play by the same rules.

## 29.3.1 Informal Proofs by Induction

Since we've spent much of this chapter looking "under the hood" at formal proofs by induction, now is a good moment to talk a little about *informal* proofs by induction.

In the real world of mathematical communication, written proofs range from extremely longwinded and pedantic to extremely brief and telegraphic. The ideal is somewhere in between, of course, but while you are getting used to the style it is better to start out at the pedantic end. Also, during the learning phase, it is probably helpful to have a clear standard to compare against. With this in mind, we offer two templates below – one for proofs by induction over *data* (i.e., where the thing we're doing induction on lives in Type) and one for proofs by induction over *evidence* (i.e., where the inductively defined thing lives in Prop). In the rest of this course, please follow one of the two for *all* of your inductive proofs.

#### Induction Over an Inductively Defined Set

#### Template:

• Theorem: <Universally quantified proposition of the form "For all n:S, P(n)," where S is some inductively defined set.>

Proof: By induction on n.

<one case for each constructor c of S...>

- Suppose n = c a1 ... ak, where <...and here we state the IH for each of the a's that has type S, if any>. We must show <...and here we restate P(c a1 ... ak)>. <go on and prove P(n) to finish the case...>
- <other cases similarly...>

#### Example:

• Theorem: For all sets X, lists I: list X, and numbers n, if length I = n then index  $(S \ n)$  I = None.

*Proof*: By induction on I.

- Suppose I = []. We must show, for all numbers n, that, if length [] = n, then index  $(S \ n) \ [] = None$ .
  - This follows immediately from the definition of index.
- Suppose I = x :: l' for some x and l', where length l' = n' implies index (S n') l' = None, for any number n'. We must show, for all n, that, if length (x::l') = n then index (S n) (x::l') = None.

Let n be a number with length l = n. Since length l = length (x::l') = S (length l'), it suffices to show that index (S (length l')) l' = None.

]] But this follows directly from the induction hypothesis, picking n' to be length l'.  $\square$ 

#### Induction Over an Inductively Defined Proposition

Since inductively defined proof objects are often called "derivation trees," this form of proof is also known as *induction on derivations*.

Template:

• Theorem: <Proposition of the form " $Q \to P$ ," where Q is some inductively defined proposition (more generally, "For all x y z, Q x y z  $\to P$  x y z")>

*Proof*: By induction on a derivation of Q. <Or, more generally, "Suppose we are given x, y, and z. We show that  $Q \times y z$  implies  $P \times y z$ , by induction on a derivation of  $Q \times y z$ "...>

<one case for each constructor **c** of Q...>

- Suppose the final rule used to show Q is c. Then <...and here we state the types of all of the a's together with any equalities that follow from the definition of the constructor and the IH for each of the a's that has type Q, if there are any>. We must show <...and here we restate P>.

<go on and prove P to finish the case...>

- <other cases similarly...>

#### Example

• Theorem: The  $\leq$  relation is transitive – i.e., for all numbers n, m, and o, if  $n \leq m$  and  $m \leq o$ , then  $n \leq o$ .

*Proof*: By induction on a derivation of  $m \leq o$ .

- Suppose the final rule used to show  $m \le o$  is le\_n. Then m = o and we must show that  $n \le m$ , which is immediate by hypothesis.
- Suppose the final rule used to show  $m \le o$  is le\_S. Then o = S o' for some o' with  $m \le o$ '. We must show that  $n \le S$  o'. By induction hypothesis,  $n \le o$ '. But then, by le\_S,  $n \le S$  o'.

# 29.4 Optional Material

The remainder of this chapter offers some additional details on how induction works in Coq, the process of building proof trees, and the "trusted computing base" that underlies Coq proofs. It can safely be skimmed on a first reading. (We recommend skimming rather than skipping over it outright: it answers some questions that occur to many Coq users at some point, so it is useful to have a rough idea of what's here.)

## 29.4.1 Induction Principles in Prop

Earlier, we looked in detail at the induction principles that Coq generates for inductively defined sets. The induction principles for inductively defined propositions like **gorgeous** are a tiny bit more complicated. As with all induction principles, we want to use the induction principle on **gorgeous** to prove things by inductively considering the possible shapes that something in **gorgeous** can have – either it is evidence that 0 is gorgeous, or it is evidence that, for some n, 3+n is gorgeous, or it is evidence that, for some n, 5+n is gorgeous and it includes evidence that n itself is. Intuitively speaking, however, what we want to prove are not statements about evidence but statements about numbers. So we want an induction principle that lets us prove properties of numbers by induction on evidence.

For example, from what we've said so far, you might expect the inductive definition of **gorgeous**... Inductive gorgeous : nat -> Prop :=  $g_0$  : gorgeous 0 |  $g_p$ lus3 : forall n, gorgeous n -> gorgeous (3+m) |  $g_p$ lus5 : forall n, gorgeous n -> gorgeous (5+m). ...to give rise to an induction principle that looks like this... gorgeous\_ind\_max : forall P : (forall n : nat, gorgeous n -> Prop), P O  $g_0$  -> (forall (m : nat) (e : gorgeous m), P m e -> P (3+m) ( $g_p$ lus3 m e) -> (forall (m : nat) (e : gorgeous m), P m e -> P (5+m) ( $g_p$ lus5 m e) -> forall (n : nat) (e : gorgeous n), P n e ... because:

- Since gorgeous is indexed by a number n (every gorgeous object e is a piece of evidence that some particular number n is gorgeous), the proposition P is parameterized by both n and e that is, the induction principle can be used to prove assertions involving both a gorgeous number and the evidence that it is gorgeous.
- Since there are three ways of giving evidence of gorgeousness (**gorgeous** has three constructors), applying the induction principle generates three subgoals:
  - We must prove that P holds for O and b\_0.
  - We must prove that, whenever n is a gorgeous number and e is an evidence of its gorgeousness, if P holds of n and e, then it also holds of 3+m and  $g_plus n$  e.
  - We must prove that, whenever n is a gorgeous number and e is an evidence of its gorgeousness, if P holds of n and e, then it also holds of 5+m and  $g_plus5$  n e.
- If these subgoals can be proved, then the induction principle tells us that P is true for all gorgeous numbers n and evidence e of their gorgeousness.

But this is a little more flexibility than we actually need or want: it is giving us a way to prove logical assertions where the assertion involves properties of some piece of *evidence* of gorgeousness, while all we really care about is proving properties of *numbers* that are gorgeous – we are interested in assertions about numbers, not about evidence. It would therefore be more convenient to have an induction principle for proving propositions P that are parameterized just by n and whose conclusion establishes P for all gorgeous numbers n: forall P: nat -> Prop, ... -> forall n: nat, gorgeous n -> P n For this reason, Coq actually generates the following simplified induction principle for **gorgeous**:

Check gorgeous\_ind.

In particular, Coq has dropped the evidence term e as a parameter of the the proposition P, and consequently has rewritten the assumption  $\forall$  (n : nat) (e: gorgeous n), ... to be  $\forall$  (n : nat), gorgeous  $n \to ...$ ; i.e., we no longer require explicit evidence of the provability of gorgeous n.

In English, gorgeous\_ind says:

- Suppose, P is a property of natural numbers (that is, P n is a Prop for every n). To show that P n holds whenever n is gorgeous, it suffices to show:
  - P holds for 0,
  - for any n, if n is gorgeous and P holds for n, then P holds for 3+n,
  - for any n, if n is gorgeous and P holds for n, then P holds for 5+n.

As expected, we can apply gorgeous\_ind directly instead of using induction.

Theorem gorgeous\_beautiful' :  $\forall n$ , gorgeous  $n \rightarrow$  beautiful n. Proof.

```
intros.
apply gorgeous_ind.
Case "g_0".
    apply b_0.
Case "g_plus3".
    intros.
    apply b_sum. apply b_3.
    apply H1.
Case "g_plus5".
    intros.
    apply b_sum. apply b_5.
    apply H2.
Qed.
```

The precise form of an Inductive definition can affect the induction principle Coq generates.

For example, in Logic, we have defined  $\leq$  as:

This definition can be streamlined a little by observing that the left-hand argument  $\boldsymbol{n}$  is the same everywhere in the definition, so we can actually make it a "general parameter" to the whole definition, rather than an argument to each constructor.

```
Inductive le (n:nat): nat \rightarrow Prop := | le_n : le n n 
| le_S : \forall m, (le n m) \rightarrow (le n (S m)).
```

```
Notation "m \le n" := (le m n).
```

The second one is better, even though it looks less symmetric. Why? Because it gives us a simpler induction principle.

#### Check le\_ind.

By contrast, the induction principle that Coq calculates for the first definition has a lot of extra quantifiers, which makes it messier to work with when proving things by induction. Here is the induction principle for the first **le**:

## 29.5 Additional Exercises

# 29.5.1 Induction Principles for other Logical Propositions

Similarly, in Logic we have defined **eq** as:

In the Coq standard library, the definition of equality is slightly different:

```
Inductive eq' (X:Type) (x:X):X\to Prop:= refl_equal': eq' X x x.
```

The advantage of this definition is that the induction principle that Coq derives for it is precisely the familiar principle of  $Leibniz\ equality$ : what we mean when we say "x and y are equal" is that every property on P that is true of x is also true of y.

#### Check eq'\_ind.

The induction principles for conjunction and disjunction are a good illustration of Coq's way of generating simplified induction principles for Inductively defined propositions, which we discussed above. You try first:

Exercise: 1 star, optional (and\_ind\_principle) See if you can predict the induction principle for conjunction.

Exercise: 1 star, optional (or\_ind\_principle) See if you can predict the induction principle for disjunction.

Check and\_ind.

From the inductive definition of the proposition and P Q Inductive and (P Q: Prop): Prop := conj : P -> Q -> (and P Q). we might expect Coq to generate this induction principle and\_ind\_max : forall (P Q: Prop) (P0 : P /\ Q -> Prop), (forall (a : P) (b : Q), P0 (conj P Q a b)) -> forall a : P /\ Q, P0 a but actually it generates this simpler and more useful one: and\_ind : forall P Q P0 : Prop, (P -> Q -> P0) -> P /\ Q -> P0 In the same way, when given the inductive definition of or P Q Inductive or (P Q: Prop): Prop := | or\_introl : P -> or P Q | or\_intror : Q -> or P Q instead of the "maximal induction principle" or\_ind\_max : forall (P Q: Prop) (P0 : P \/ Q -> Prop), (forall a : P, P0 (or\_introl P Q a)) -> (forall b : Q, P0 (or\_intror P Q b)) -> forall o : P \/ Q, P0 o what Coq actually generates is this: or\_ind : forall P Q P0 : Prop, (P -> P0) -> (Q -> P0) -> P \/ Q -> P0 |

Exercise: 1 star, optional (False\_ind\_principle) Can you predict the induction principle for falsehood?

Here's the induction principle that Coq generates for existentials:

#### Check ex\_ind.

This induction principle can be understood as follows: If we have a function f that can construct evidence for Q given any witness of type X together with evidence that this witness

has property P, then from a proof of  $\mathbf{ex} \times \mathbf{P}$  we can extract the witness and evidence that must have been supplied to the constructor, give these to  $\mathbf{f}$ , and thus obtain a proof of Q.

## 29.5.2 Explicit Proof Objects for Induction

Although tactic-based proofs are normally much easier to work with, the ability to write a proof term directly is sometimes very handy, particularly when we want Coq to do something slightly non-standard.

Recall the induction principle on naturals that Coq generates for us automatically from the Inductive declation for **nat**.

#### Check nat\_ind.

There's nothing magic about this induction lemma: it's just another Coq lemma that requires a proof. Coq generates the proof automatically too...

```
Print nat\_ind.

Print nat\_rect.
```

We can read this as follows: Suppose we have evidence f that P holds on 0, and evidence  $f\theta$  that  $\forall$  n:nat, P n  $\rightarrow$  P (S n). Then we can prove that P holds of an arbitrary nat n via a recursive function F (here defined using the expression form Fix rather than by a top-level Fixpoint declaration). F pattern matches on n:

- If it finds 0, F uses f to show that P n holds.
- If it finds S  $n\theta$ , F applies itself recursively on  $n\theta$  to obtain evidence that P  $n\theta$  holds; then it applies  $f\theta$  on that evidence to show that P (S n) holds.

F is just an ordinary recursive function that happens to operate on evidence in Prop rather than on terms in Set.

We can adapt this approach to proving nat\_ind to help prove non-standard induction principles too. Recall our desire to prove that

```
\forall n : nat, even n \rightarrow ev n.
```

Attempts to do this by standard induction on n fail, because the induction principle only lets us proceed when we can prove that even  $n \to \text{even } (S \ n)$  – which is of course never provable. What we did in Logic was a bit of a hack:

```
Theorem even_ev : \forall n : nat, (even n \rightarrow ev n) \land (even (S n) \rightarrow ev (S n)).
```

We can make a much better proof by defining and proving a non-standard induction principle that goes "by twos":

#### Definition nat\_ind2:

```
\begin{array}{l} \forall \; (P: \mathbf{nat} \rightarrow \mathtt{Prop}), \\ P \; 0 \rightarrow \\ P \; 1 \rightarrow \\ (\forall \; n: \; \mathbf{nat}, \; P \; n \rightarrow P \; (\mathsf{S}(\mathsf{S} \; n))) \rightarrow \\ \forall \; n: \; \mathbf{nat} \; , \; P \; n := \end{array}
```

```
\begin{array}{l} \operatorname{fun}\, P\Rightarrow \operatorname{fun}\, P0\Rightarrow \operatorname{fun}\, P1\Rightarrow \operatorname{fun}\, PSS\Rightarrow\\ \operatorname{fix}\, f\, \left(n{:}\mathsf{nat}\right):=\operatorname{match}\, n\, \operatorname{with}\\ 0\Rightarrow P0\\ \mid 1\Rightarrow P1\\ \mid \operatorname{S}\left(\operatorname{S}\, n'\right)\Rightarrow PSS\, n'\, (f\, n')\\ \operatorname{end}. \end{array}
```

Once you get the hang of it, it is entirely straightforward to give an explicit proof term for induction principles like this. Proving this as a lemma using tactics is much less intuitive (try it!).

The induction ... using tactic variant gives a convenient way to specify a non-standard induction principle like this.

```
Lemma even__ev': \forall n, even n \to \mathbf{ev} \ n.

Proof.

intros.

induction n as [ \ | \ | n'] using nat_ind2.

Case "even 0".

apply ev_0.

Case "even 1".

inversion H.

Case "even (S(S \ n'))".

apply ev_SS.

apply IHn'. unfold even. unfold even in H. simpl in H. apply H.

Qed.
```

#### 29.5.3 The Coq Trusted Computing Base

One issue that arises with any automated proof assistant is "why trust it?": what if there is a bug in the implementation that renders all its reasoning suspect?

While it is impossible to allay such concerns completely, the fact that Coq is based on the Curry-Howard correspondence gives it a strong foundation. Because propositions are just types and proofs are just terms, checking that an alleged proof of a proposition is valid just amounts to *type-checking* the term. Type checkers are relatively small and straightforward programs, so the "trusted computing base" for Coq – the part of the code that we have to believe is operating correctly – is small too.

What must a typechecker do? Its primary job is to make sure that in each function application the expected and actual argument types match, that the arms of a match expression are constructor patterns belonging to the inductive type being matched over and all arms of the match return the same type, and so on.

There are a few additional wrinkles:

• Since Coq types can themselves be expressions, the checker must normalize these (by using the computation rules) before comparing them.

- The checker must make sure that match expressions are *exhaustive*. That is, there must be an arm for every possible constructor. To see why, consider the following alleged proof object: Definition or\_bogus: forall P Q, P \/ Q -> P := fun (P Q: Prop) (A:P \/ Q) => match A with | or\_introl H => H end. All the types here match correctly, but the match only considers one of the possible constructors for **or**. Coq's exhaustiveness check will reject this definition.
- The checker must make sure that each fix expression terminates. It does this using a syntactic check to make sure that each recursive call is on a subexpression of the original argument. To see why this is essential, consider this alleged proof: Definition nat\_false: forall (n:nat), False:= fix f (n:nat): False:= f n. Again, this is perfectly well-typed, but (fortunately) Coq will reject it.

Note that the soundness of Coq depends only on the correctness of this typechecking engine, not on the tactic machinery. If there is a bug in a tactic implementation (and this certainly does happen!), that tactic might construct an invalid proof term. But when you type Qed, Coq checks the term for validity from scratch. Only lemmas whose proofs pass the type-checker can be used in further proof developments.

# Chapter 30

# Library ProofObjects

# 30.1 ProofObjects: Working with Explicit Evidence in Coq

Require Export Logic.

We have seen that Coq has mechanisms both for *programming*, using inductive data types (like **nat** or **list**) and functions over these types, and for *proving* properties of these programs, using inductive propositions (like **ev** or **eq**), implication, and universal quantification. So far, we have treated these mechanisms as if they were quite separate, and for many purposes this is a good way to think. But we have also seen hints that Coq's programming and proving facilities are closely related. For example, the keyword Inductive is used to declare both data types and propositions, and  $\rightarrow$  is used both to describe the type of functions on data and logical implication. This is not just a syntactic accident! In fact, programs and proofs in Coq are almost the same thing. In this chapter we will study how this works.

We have already seen the fundamental idea: provability in Coq is represented by concrete evidence. When we construct the proof of a basic proposition, we are actually building a tree of evidence, which can be thought of as a data structure. If the proposition is an implication like  $A \to B$ , then its proof will be an evidence transformer: a recipe for converting evidence for A into evidence for B. So at a fundamental level, proofs are simply programs that manipulate evidence.

Q. If evidence is data, what are propositions themselves?

A. They are types!

Look again at the formal definition of the **beautiful** property.

#### Print beautiful.

The trick is to introduce an alternative pronunciation of ":". Instead of "has type," we can also say "is a proof of." For example, the second line in the definition of **beautiful** declares that  $b_-0$ : **beautiful** 0. Instead of " $b_-0$  has type **beautiful** 0," we can say that " $b_-0$  is a proof of **beautiful** 0." Similarly for  $b_-3$  and  $b_-5$ .

This pun between types and propositions (between : as "has type" and : as "is a proof of" or "is evidence for") is called the *Curry-Howard correspondence*. It proposes a deep connection between the world of logic and the world of computation.

```
propositions ~ types
proofs ~ data values
```

Many useful insights follow from this connection. To begin with, it gives us a natural interpretation of the type of b\_sum constructor:

Check b\_sum.

This can be read " $b\_sum$  is a constructor that takes four arguments – two numbers, n and m, and two values, of types **beautiful** n and **beautiful** m – and yields evidence for the proposition **beautiful** (n+m)."

Now let's look again at a previous proof involving beautiful.

Theorem eight\_is\_beautiful: beautiful 8.

Proof.

```
apply b_sum with (n:=3) (m:=5). apply b_3. apply b_5. Qed.
```

Just as with ordinary data values and functions, we can use the Print command to see the *proof object* that results from this proof script.

Print eight\_is\_beautiful.

In view of this, we might wonder whether we can write such an expression ourselves. Indeed, we can:

```
Check (b_sum 3.5 b_{-}3 b_{-}5).
```

The expression b\_sum 3 5 b\_3 b\_5 can be thought of as instantiating the parameterized constructor b\_sum with the specific arguments 3 5 and the corresponding proof objects for its premises beautiful 3 and beautiful 5 (Coq is smart enough to figure out that 3+5=8). Alternatively, we can think of b\_sum as a primitive "evidence constructor" that, when applied to two particular numbers, wants to be further applied to evidence that those two numbers are beautiful; its type, [ $\forall$  n m, beautiful n  $\rightarrow$  beautiful m  $\rightarrow$  beautiful (n+m), expresses this functionality, in the same way that the polymorphic type [ $\forall$  X, list X] in the previous chapter expressed the fact that the constructor [nil] can be thought of as a function from types to empty lists with elements of that type.

This gives us an alternative way to write the proof that 8 is beautiful:

Theorem eight\_is\_beautiful': **beautiful** 8. Proof.

```
apply (b_sum 3\ 5\ b\_3\ b\_5). Qed.
```

Notice that we're using apply here in a new way: instead of just supplying the *name* of a hypothesis or previously proved theorem whose type matches the current goal, we are supplying an *expression* that directly builds evidence with the required type.

#### 30.1.1 Proof Scripts and Proof Objects

These proof objects lie at the core of how Coq operates.

When Coq is following a proof script, what is happening internally is that it is gradually constructing a proof object – a term whose type is the proposition being proved. The tactics between the Proof command and the Qed instruct Coq how to build up a term of the required type. To see this process in action, let's use the Show Proof command to display the current state of the proof tree at various points in the following tactic proof.

```
Theorem eight_is_beautiful": beautiful 8.

Proof.

Show Proof.

apply b_sum with (n:=3) (m:=5).

Show Proof.

apply b_3.

Show Proof.

apply b_5.

Show Proof.

Qed.
```

At any given moment, Coq has constructed a term with some "holes" (indicated by ?1, ?2, and so on), and it knows what type of evidence is needed at each hole.

Each of the holes corresponds to a subgoal, and the proof is finished when there are no more subgoals. At this point, the **Theorem** command gives a name to the evidence we've built and stores it in the global context.

Tactic proofs are useful and convenient, but they are not essential: in principle, we can always construct the required evidence by hand, as shown above. Then we can use Definition (rather than Theorem) to give a global name directly to a piece of evidence.

```
Definition eight_is_beautiful''': beautiful 8 := b_sum 3 5 b_3 b_5.
```

All these different ways of building the proof lead to exactly the same evidence being saved in the global environment.

```
Print eight_is_beautiful.
Print eight_is_beautiful'.
Print eight_is_beautiful''.
Print eight_is_beautiful'''.
```

Exercise: 1 star (six\_is\_beautiful) Give a tactic proof and a proof object showing that 6 is beautiful.

```
Theorem six_is_beautiful:

beautiful 6.

Proof.

Admitted.
```

```
Definition six_is_beautiful': beautiful 6:=
    admit.

□

Exercise: 1 star (nine_is_beautiful) Give a tactic proof and a proof object showing that 9 is beautiful.

Theorem nine_is_beautiful:
    beautiful 9.

Proof.
    Admitted.

Definition nine_is_beautiful': beautiful 9:=
    admit.
    □
```

#### 30.1.2 Quantification, Implications and Functions

In Coq's computational universe (where we've mostly been living until this chapter), there are two sorts of values with arrows in their types: *constructors* introduced by Inductive-ly defined data types, and *functions*.

Similarly, in Coq's logical universe, there are two ways of giving evidence for an implication: constructors introduced by Inductive-ly defined propositions, and... functions!

For example, consider this statement:

```
Theorem b_plus3: \forall n, beautiful n \to \text{beautiful } (3+n). Proof. intros n H. apply b_sum. apply b_3. apply H. Qed.
```

What is the proof object corresponding to b\_plus3?

We're looking for an expression whose type is  $\forall$  n, beautiful  $n \rightarrow$  beautiful (3+n) – that is, a function that takes two arguments (one number and a piece of evidence) and returns a piece of evidence! Here it is:

```
Definition b_plus3' : \forall n, beautiful n \rightarrow beautiful (3+n) :=  fun (n : nat) \Rightarrow fun (H : beautiful n) \Rightarrow b_sum 3 n b_3 H.

Check b_plus3'.
```

Recall that fun  $n \Rightarrow blah$  means "the function that, given n, yields blah." Another equivalent way to write this definition is:

```
Definition b_plus3'' (n : nat) (H : beautiful n) : beautiful (3+n) :=
```

```
b_{sum 3} n b_{3} H.
```

Check b\_plus3".

When we view the proposition being proved by b\_plus3 as a function type, one aspect of it may seem a little unusual. The second argument's type, **beautiful** n, mentions the *value* of the first argument, n. While such *dependent types* are not commonly found in programming languages, even functional ones like ML or Haskell, they can be useful there too.

Notice that both implication  $(\rightarrow)$  and quantification  $(\forall)$  correspond to functions on evidence. In fact, they are really the same thing:  $\rightarrow$  is just a shorthand for a degenerate use of  $\forall$  where there is no dependency, i.e., no need to give a name to the type on the LHS of the arrow.

For example, consider this proposition:

```
Definition beautiful_plus3 : Prop := \forall n, \forall (E : \mathbf{beautiful} \ n), \mathbf{beautiful} \ (n+3).
```

A proof term inhabiting this proposition would be a function with two arguments: a number  ${\sf n}$  and some evidence E that  ${\sf n}$  is beautiful. But the name E for this evidence is not used in the rest of the statement of  $funny\_prop1$ , so it's a bit silly to bother making up a name for it. We could write it like this instead, using the dummy identifier  $\_$  in place of a real name:

```
Definition beautiful_plus3': Prop := \forall n, \forall (\_: beautiful \ n), beautiful (n+3).

Or, equivalently, we can write it in more familiar notation:

Definition beatiful_plus3'': Prop := \forall n, beautiful \ n \rightarrow beautiful \ (n+3).

In general, "P \rightarrow Q" is just syntactic sugar for "\forall (\_:P), Q".

Exercise: 3 stars (b_times2) First prove this theorem using tactics.

Theorem b_times2: \forall n, beautiful \ n \rightarrow beautiful \ (2 \times n).

Proof.

Admitted.

Now write a corresponding proof object directly.

Definition b_times2': \forall n, beautiful \ n \rightarrow beautiful \ (2 \times n) := admit.

\square
```

Exercise: 2 stars, optional (gorgeous\_plus13\_po) Give a proof object corresponding to the theorem gorgeous\_plus13 from Prop.v

```
Definition gorgeous_plus13_po: \forall n, gorgeous n \rightarrow gorgeous (13+n):= admit.
```

It is particularly revealing to look at proof objects involving the logical connectives that we defined with inductive propositions in Logic.v.

```
Theorem and example:
```

```
(beautiful 0) ∧ (beautiful 3).
Proof.
apply conj.
apply b_0.
apply b_3. Qed.
```

Let's take a look at the proof object for the above theorem.

Print and\_example.

Note that the proof is of the form conj (beautiful 0) (beautiful 3) (...pf of beautiful 3...) (...pf of beautiful 3...) as you'd expect, given the type of conj.

**Exercise:** 1 star, optional (case\_proof\_objects) The *Case* tactics were commented out in the proof of and\_example to avoid cluttering the proof object. What would you guess the proof object will look like if we uncomment them? Try it and see. □

```
Theorem and commut: \forall \ P \ Q: Prop, P \land Q \rightarrow Q \land P.

Proof.

intros P \ Q \ H.

inversion H as [HP \ HQ].

split.

apply HQ.

apply HP. Qed.
```

Once again, we have commented out the Case tactics to make the proof object for this theorem easier to understand. It is still a little complicated, but after performing some simple reduction steps, we can see that all that is really happening is taking apart a record containing evidence for  $\mathsf{P}$  and Q and rebuilding it in the opposite order:

Print and\_commut.

After simplifying some direct application of fun expressions to arguments, we get:

Exercise: 2 stars, optional (conj\_fact) Construct a proof object demonstrating the following proposition.

Exercise: 2 stars, advanced (beautiful\_iff\_gorgeous) We have seen that the families of propositions beautiful and gorgeous actually characterize the same set of numbers. Prove that beautiful  $n \leftrightarrow gorgeous n$  for all n. Just for fun, write your proof as an explicit proof object, rather than using tactics. (*Hint*: if you make use of previously defined theorems, you should only need a single line!)

```
Definition beautiful_iff_gorgeous : \forall n, beautiful n \leftrightarrow gorgeous n := admit. \Box
```

Exercise: 2 stars, optional (or\_commut") Try to write down an explicit proof object for or\_commut (without using Print to peek at the ones we already defined!).

Recall that we model an existential for a property as a pair consisting of a witness value and a proof that the witness obeys that property. We can choose to construct the proof explicitly.

For example, consider this existentially quantified proposition:

```
Definition some_nat_is_even : Prop :=
ex nat ev.
```

To prove this proposition, we need to choose a particular number as witness - say, 4 - and give some evidence that that number is even.

```
Definition snie : some_nat_is_even := ex_intro _ev 4 (ev_SS 2 (ev_SS 0 ev_0)).
```

Exercise: 2 stars (ex\_beautiful\_Sn) Complete the definition of the following proof object:

```
 \begin{array}{l} {\tt Definition}\; {\tt p}: \; \mathbf{ex}\; \mathbf{nat}\; ({\tt fun}\; n \Rightarrow \mathbf{beautiful}\; ({\tt S}\; n)) := \\ {\tt admit}. \\ & \square \\ \end{array}
```

#### 30.1.3 Giving Explicit Arguments to Lemmas and Hypotheses

Even when we are using tactic-based proof, it can be very useful to understand the underlying functional nature of implications and quantification.

For example, it is often convenient to apply or rewrite using a lemma or hypothesis with one or more quantifiers or assumptions already instantiated in order to direct what happens. For example:

```
Check plus_comm.
```

```
Lemma plus_comm_r : \forall a \ b \ c, \ c + (b + a) = c + (a + b). Proof.
```

```
intros a b c.
  rewrite (plus_comm b a). reflexivity. Qed.
  In this case, giving just one argument would be sufficient.

Lemma plus_comm_r': ∀ a b c, c + (b + a) = c + (a + b).

Proof.
  intros a b c.
  rewrite (plus_comm b).
  reflexivity. Qed.

Arguments must be given in order, but wildcards (_) may be used to skip arguments that Coq can infer.

Lemma plus_comm_r'': ∀ a b c, c + (b + a) = c + (a + b).

Proof.
```

The author of a lemma can choose to declare easily inferable arguments to be implicit, just as with functions and constructors.

The with clauses we've already seen is really just a way of specifying selected arguments by name rather than position:

```
Lemma plus_comm_r''': \forall \ a \ b \ c, \ c + (b + a) = c + (a + b). Proof.

intros a \ b \ c.

rewrite plus\_comm with (n := b).

reflexivity. Qed.
```

Exercise: 2 stars (trans\_eq\_example\_redux) Redo the proof of the following theorem (from MoreCoq.v) using an apply of trans\_eq but not using a with clause.

```
Example trans_eq_example' : \forall (a b c d e f : nat),  [a;b] = [c;d] \rightarrow \\ [c;d] = [e;f] \rightarrow \\ [a;b] = [e;f].  Proof.  Admitted.
```

#### 30.1.4 Programming with Tactics

If we can build proofs with explicit terms rather than tactics, you may be wondering if we can build programs using tactics rather than explicit terms. Sure!

```
Definition add1: nat \rightarrow nat.
```

intros a b c.

reflexivity. Qed.

rewrite (plus\_comm \_ a).

intro n. Show Proof. apply S. Show Proof. apply n. Defined. Print add1. Eval compute in add1 2.

Notice that we terminate the Definition with a . rather than with := followed by a term. This tells Coq to enter proof scripting mode to build an object of type  $\mathbf{nat} \to \mathbf{nat}$ . Also, we terminate the proof with Defined rather than Qed; this makes the definition transparent so that it can be used in computation like a normally-defined function.

This feature is mainly useful for writing functions with dependent types, which we won't explore much further in this book. But it does illustrate the uniformity and orthogonality of the basic ideas in Coq.

# Chapter 31

# Library Logic

### 31.1 Logic: Logic in Coq

Require Export MoreProp.

Coq's built-in logic is very small: the only primitives are Inductive definitions, universal quantification  $(\forall)$ , and implication  $(\rightarrow)$ , while all the other familiar logical connectives – conjunction, disjunction, negation, existential quantification, even equality – can be encoded using just these.

This chapter explains the encodings and shows how the tactics we've seen can be used to carry out standard forms of logical reasoning involving these connectives.

### 31.2 Conjunction

The logical conjunction of propositions P and Q can be represented using an Inductive definition with one constructor.

```
Inductive and (P \ Q : Prop) : Prop := conj : P \rightarrow Q \rightarrow (and P \ Q).
```

Note that, like the definition of **ev** in a previous chapter, this definition is parameterized; however, in this case, the parameters are themselves propositions, rather than numbers.

The intuition behind this definition is simple: to construct evidence for and P Q, we must provide evidence for P and evidence for Q. More precisely:

- conj p q can be taken as evidence for and P Q if p is evidence for P and q is evidence for Q; and
- this is the *only* way to give evidence for **and** P Q that is, if someone gives us evidence for **and** P Q, we know it must have the form **conj** p q, where p is evidence for P and q is evidence for Q.

Since we'll be using conjunction a lot, let's introduce a more familiar-looking infix notation for it.

```
Notation "P /\setminus Q" := (and P Q) : type\_scope.
```

(The *type\_scope* annotation tells Coq that this notation will be appearing in propositions, not values.)

Consider the "type" of the constructor conj:

#### Check conj.

Notice that it takes 4 inputs – namely the propositions P and Q and evidence for P and Q – and returns as output the evidence of P  $\wedge$  Q.

Besides the elegance of building everything up from a tiny foundation, what's nice about defining conjunction this way is that we can prove statements involving conjunction using the tactics that we already know. For example, if the goal statement is a conjuction, we can prove it by applying the single constructor conj, which (as can be seen from the type of conj) solves the current goal and leaves the two parts of the conjunction as subgoals to be proved separately.

```
Theorem and example:
```

```
(beautiful 0) ∧ (beautiful 3).
Proof.
apply conj.
Case "left". apply b_0.
Case "right". apply b_3. Qed.
```

Just for convenience, we can use the tactic split as a shorthand for apply conj.

Conversely, the inversion tactic can be used to take a conjunction hypothesis in the context, calculate what evidence must have been used to build it, and add variables representing this evidence to the proof context.

```
Theorem proj1: \forall P \ Q: Prop, P \land Q \rightarrow P.

Proof.

intros P \ Q \ H.

inversion H as [HP \ HQ].

apply HP. Qed.

Exercise: 1 star, optional (proj2) Theorem proj2: \forall P \ Q: Prop, P \land Q \rightarrow Q.
```

```
Proof. Admitted. \square Theorem and commut: \forall \ P \ Q: Prop, P \land Q \rightarrow Q \land P. Proof. intros P \ Q \ H. inversion H as [HP \ HQ]. split. Case \text{ "left". apply } HQ. Case \text{ "right". apply } HP. \text{ Qed.}
```

**Exercise: 2 stars (and\_assoc)** In the following proof, notice how the *nested pattern* in the inversion breaks the hypothesis  $H: P \wedge (Q \wedge R)$  down into HP: P, HQ: Q, and HR: R. Finish the proof from there:

```
Theorem and assoc : \forall P \ Q \ R : Prop, P \land (Q \land R) \rightarrow (P \land Q) \land R.

Proof.

intros P \ Q \ R \ H.

inversion H as [HP \ [HQ \ HR]].

Admitted.
```

Exercise: 2 stars (even\_\_ev) Now we can prove the other direction of the equivalence of even and ev, which we left hanging in chapter Prop. Notice that the left-hand conjunct here is the statement we are actually interested in; the right-hand conjunct is needed in order to make the induction hypothesis strong enough that we can carry out the reasoning in the inductive step. (To see why this is needed, try proving the left conjunct by itself and observe where things get stuck.)

```
Theorem even__ev : \forall n : \operatorname{nat},   (even n \to \operatorname{ev} n) \wedge (even (S n) \to \operatorname{ev} (S n)). Proof.   Admitted. \Box
```

#### 31.2.1 Iff

The handy "if and only if" connective is just the conjunction of two implications.

```
Definition iff (P \ Q : \mathsf{Prop}) := (P \to Q) \land (Q \to P).

Notation "P <-> Q" := (iff P \ Q)

(at level 95, no associativity)
```

```
: type\_scope. Theorem iff_implies: \forall \ P \ Q : Prop, (P \leftrightarrow Q) \rightarrow P \rightarrow Q. Proof. intros P \ Q \ H. inversion H as [HAB \ HBA]. apply HAB. Qed. Theorem iff_sym: \forall \ P \ Q : Prop, (P \leftrightarrow Q) \rightarrow (Q \leftrightarrow P). Proof. intros P \ Q \ H. inversion H as [HAB \ HBA]. split. Case \ "->". \ apply \ HBA. Case \ "->". \ apply \ HAB. \ Qed.
```

Exercise: 1 star, optional (iff\_properties) Using the above proof that  $\leftrightarrow$  is symmetric (iff\_sym) as a guide, prove that it is also reflexive and transitive.

```
\begin{array}{l} \text{Theorem iff\_refl}: \ \forall \ P: \texttt{Prop}, \\ P \leftrightarrow P. \\ \\ \texttt{Proof.} \\ Admitted. \\ \\ \text{Theorem iff\_trans}: \ \forall \ P \ Q \ R: \texttt{Prop}, \\ (P \leftrightarrow Q) \rightarrow (Q \leftrightarrow R) \rightarrow (P \leftrightarrow R). \\ \\ \texttt{Proof.} \\ Admitted. \end{array}
```

Hint: If you have an iff hypothesis in the context, you can use inversion to break it into two separate implications. (Think about why this works.)  $\Box$ 

Some of Coq's tactics treat iff statements specially, thus avoiding the need for some low-level manipulation when reasoning with them. In particular, rewrite can be used with iff statements, not just equalities.

#### 31.3 Disjunction

Disjunction ("logical or") can also be defined as an inductive proposition.

```
Inductive or (P \ Q : \operatorname{Prop}) : \operatorname{Prop} := | \operatorname{or\_introl} : P \to \operatorname{or} P \ Q | \operatorname{or\_intror} : Q \to \operatorname{or} P \ Q.
Notation "P \/ Q" := (or P \ Q) : type\_scope.
Consider the "type" of the constructor or\_introl:
```

Check or\_introl.

It takes 3 inputs, namely the propositions P, Q and evidence of P, and returns, as output, the evidence of  $P \vee Q$ . Next, look at the type of or\_intror:

Check or\_intror.

It is like or\_introl but it requires evidence of Q instead of evidence of P. Intuitively, there are two ways of giving evidence for  $P \vee Q$ :

- give evidence for P (and say that it is P you are giving evidence for this is the function of the or\_introl constructor), or
- give evidence for Q, tagged with the or\_intror constructor.

Since  $P \lor Q$  has two constructors, doing inversion on a hypothesis of type  $P \lor Q$  yields two subgoals.

```
Theorem or_commut : \forall \ P \ Q : Prop, P \lor Q \to Q \lor P. Proof. intros P \ Q \ H. inversion H as [HP \mid HQ]. Case \ "left". apply or_intror. apply <math>HP. Case \ "right". apply or_introl. apply <math>HQ. Qed.
```

From here on, we'll use the shorthand tactics left and right in place of apply or\_introl and apply or\_intror.

```
Theorem or_commut': \forall P \ Q : Prop,
  P \vee Q \rightarrow Q \vee P.
Proof.
  intros P Q H.
  inversion H as [HP \mid HQ].
     Case "left". right. apply HP.
     Case "right". left. apply HQ. Qed.
Theorem or_distributes_over_and_1 : \forall P \ Q \ R : Prop,
  P \vee (Q \wedge R) \rightarrow (P \vee Q) \wedge (P \vee R).
Proof.
  intros P Q R. intros H. inversion H as [HP \mid [HQ HR]].
     Case "left". split.
       SCase "left". left. apply HP.
       SCase "right". left. apply HP.
     Case "right". split.
       SCase "left". right. apply HQ.
       SCase "right". right. apply HR. Qed.
```

```
Exercise: 2 stars (or_distributes_over_and_2) Theorem or_distributes_over_and_2: \forall P \ Q \ R : Prop, (P \lor Q) \land (P \lor R) \rightarrow P \lor (Q \land R). Proof. Admitted. \Box

Exercise: 1 star, optional (or_distributes_over_and) Theorem or_distributes_over_and: \forall P \ Q \ R : Prop, P \lor (Q \land R) \leftrightarrow (P \lor Q) \land (P \lor R). Proof. Admitted. \Box
```

#### 31.3.1 Relating $\wedge$ and $\vee$ with andb and orb (advanced)

We've already seen several places where analogous structures can be found in Coq's computational (Type) and logical (Prop) worlds. Here is one more: the boolean operators and and orb are clearly analogs of the logical connectives  $\wedge$  and  $\vee$ . This analogy can be made more precise by the following theorems, which show how to translate knowledge about and and orb's behaviors on certain inputs into propositional facts about those inputs.

```
Theorem andb_prop : \forall b c,
  andb b c = true \rightarrow b = true \land c = true.
Proof.
  intros b \ c \ H.
  destruct b.
     Case "b = true". destruct c.
        SCase \ "c = true". apply conj. reflexivity. reflexivity.
        SCase "c = false". inversion H.
     Case "b = false". inversion H. Qed.
Theorem and b_{true_intro} : \forall b c,
  b = \mathsf{true} \land c = \mathsf{true} \to \mathsf{andb} \ b \ c = \mathsf{true}.
Proof.
  intros b c H.
  inversion H.
  rewrite H0. rewrite H1. reflexivity. Qed.
Exercise: 2 stars, optional (bool_prop) Theorem and b_false : \forall b c,
  andb b c = false \rightarrow b = false \lor c = false.
Proof.
    Admitted.
Theorem orb_prop : \forall b c,
```

```
orb b c = true \rightarrow b = true \lor c = true. Proof. 
 Admitted. Theorem orb_false_elim : \forall b c, orb b c = false \rightarrow b = false \land c = false. Proof. 
 Admitted.
```

#### 31.4 Falsehood

Logical falsehood can be represented in Coq as an inductively defined proposition with no constructors.

```
Inductive False : Prop := .
```

Intuition: **False** is a proposition for which there is no way to give evidence.

Since False has no constructors, inverting an assumption of type False always yields zero subgoals, allowing us to immediately prove any goal.

```
Theorem False_implies_nonsense:
```

```
False \rightarrow 2 + 2 = 5.

Proof.
intros contra.
inversion contra. Qed.
```

How does this work? The inversion tactic breaks *contra* into each of its possible cases, and yields a subgoal for each case. As *contra* is evidence for **False**, it has *no* possible cases, hence, there are no possible subgoals and the proof is done.

Conversely, the only way to prove **False** is if there is already something nonsensical or contradictory in the context:

```
Theorem nonsense_implies_False:
```

```
2 + 2 = 5 \rightarrow \mathsf{False}. Proof. intros contra.
```

inversion contra. Qed.

Actually, since the proof of False\_implies\_nonsense doesn't actually have anything to do with the specific nonsensical thing being proved; it can easily be generalized to work for an arbitrary P:

```
Theorem ex_falso_quodlibet : \forall (P:Prop),

False \rightarrow P.

Proof.

intros P contra.

inversion contra. Qed.
```

The Latin *ex falso quodlibet* means, literally, "from falsehood follows whatever you please." This theorem is also known as the *principle of explosion*.

#### 31.4.1 Truth

Since we have defined falsehood in Coq, one might wonder whether it is possible to define truth in the same way. We can.

Exercise: 2 stars, advanced (True) Define True as another inductively defined proposition. (The intution is that True should be a proposition for which it is trivial to give evidence.)

However, unlike **False**, which we'll use extensively, **True** is used fairly rarely. By itself, it is trivial (and therefore uninteresting) to prove as a goal, and it carries no useful information as a hypothesis. But it can be useful when defining complex **Props** using conditionals, or as a parameter to higher-order **Props**.

#### 31.5 Negation

The logical complement of a proposition P is written **not** P or, for shorthand,  $\neg P$ :

Definition not  $(P:Prop) := P \rightarrow False$ .

The intuition is that, if P is not true, then anything at all (even False) follows from assuming P.

```
Notation "\tilde{x}" := (not x) : type\_scope.
```

Check not.

It takes a little practice to get used to working with negation in Coq. Even though you can see perfectly well why something is true, it can be a little hard at first to get things into the right configuration so that Coq can see it! Here are proofs of a few familiar facts about negation to get you warmed up.

```
Theorem not_False: \neg False. 
Proof. 
unfold not. intros H. inversion H. Qed. 
Theorem contradiction_implies_anything: \forall \ P \ Q: Prop, (P \land \neg P) \rightarrow Q. 
Proof. 
intros P \ Q \ H. inversion H as [HP \ HNA]. unfold not in HNA. 
apply HNA in HP. inversion HP. Qed.
```

Theorem double\_neg :  $\forall P : Prop$ ,

```
P \rightarrow \tilde{P}.
Proof.
  intros P H. unfold not. intros G. apply G. apply H. Qed.
Exercise: 2 stars, advanced (double_neg_inf) Write an informal proof of double_neg:
    Theorem: P implies ~~P, for any proposition P.
   Proof: \square
Exercise: 2 stars (contrapositive) Theorem contrapositive: \forall P Q: Prop.
  (P \to Q) \to (\neg Q \to \neg P).
Proof.
   Admitted.
   Exercise: 1 star (not_both_true_and_false) Theorem not_both_true_and_false : \forall P
: Prop.
  \neg (P \land \neg P).
Proof.
   Admitted.
   Exercise: 1 star, advanced (informal_not_PNP) Write an informal proof (in English)
of the proposition \forall P : Prop, \ ^{\sim}(P \land \neg P).
   Theorem five_not_even :
  \neg ev 5.
Proof.
  unfold not. intros Hev5. inversion Hev5 as [n Hev3 Heqn].
  inversion Hev3 as [n' Hev1 Heqn']. inversion Hev1. Qed.
```

Exercise: 1 star (ev\_not\_ev\_S) Theorem five\_not\_even confirms the unsurprising fact that five is not an even number. Prove this more interesting fact:

```
Theorem ev_not_ev_S : \forall n, ev n \to \neg ev ( S n ). Proof. unfold not. intros n H. induction H. Admitted. \Box
```

Note that some theorems that are true in classical logic are *not* provable in Coq's (constructive) logic. E.g., let's look at how this proof gets stuck...

```
Theorem classic_double_neg : \forall P : Prop, \neg P \rightarrow P.
```

```
Proof. intros P H. unfold not in H. Abort.
```

Exercise: 5 stars, advanced, optional (classical\_axioms) For those who like a challenge, here is an exercise taken from the Coq'Art book (p. 123). The following five statements are often considered as characterizations of classical logic (as opposed to constructive logic, which is what is "built in" to Coq). We can't prove them in Coq, but we can consistently add any one of them as an unproven axiom if we wish to work in classical logic. Prove that these five propositions are equivalent.

#### 31.5.1 Inequality

```
Saying x \neq y is just the same as saying \tilde{x}(x = y).
Notation "x <> y" := (\neg (x = y)) : type\_scope.
```

Since inequality involves a negation, it again requires a little practice to be able to work with it fluently. Here is one very useful trick. If you are trying to prove a goal that is nonsensical (e.g., the goal state is false = true), apply the lemma ex\_falso\_quodlibet to change the goal to False. This makes it easier to use assumptions of the form  $\neg P$  that are available in the context – in particular, assumptions of the form  $x \neq y$ .

```
Theorem not_false_then_true : \forall \ b : bool, b \neq \text{false} \rightarrow b = \text{true}.

Proof.

intros b H. destruct b.

Case "b = true". reflexivity.

Case "b = false".

unfold not in H.

apply ex_falso_quodlibet.

apply H. reflexivity. Qed.
```

```
Exercise: 2 stars (false_beq_nat) Theorem false_beq_nat: \forall n m : nat,
     n \neq m \rightarrow
     beq_nat n m = false.
Proof.
   Admitted.
   Exercise: 2 stars, optional (beq_nat_false) Theorem beq_nat_false: \forall n m,
  beq_nat n m = false \rightarrow n \neq m.
Proof.
   Admitted.
   Exercise: 2 stars, optional (ble_nat_false) Theorem ble_nat_false: \forall n m,
  ble_nat n m = false \rightarrow ~ (n < m).
Proof.
   Admitted.
```

### 31.6 Existential Quantification

Another critical logical connective is *existential quantification*. We can express it with the following definition:

```
Inductive ex (X:Type) (P: X \rightarrow Prop) : Prop := ex_intro : <math>\forall (witness:X), P \ witness \rightarrow ex \ X \ P.
```

That is, **ex** is a family of propositions indexed by a type X and a property P over X. In order to give evidence for the assertion "there exists an x for which the property P holds" we must actually name a witness – a specific value x – and then give evidence for P x, i.e., evidence that x has the property P.

Coq's Notation facility can be used to introduce more familiar notation for writing existentially quantified propositions, exactly parallel to the built-in syntax for universally quantified propositions. Instead of writing **ex nat ev** to express the proposition that there exists some number that is even, for example, we can write  $\exists x: nat, ev x$ . (It is not necessary to understand exactly how the Notation definition works.)

```
Notation "'exists' x , p" := (ex _ (fun x \Rightarrow p)) (at level 200, x ident, right associativity) : type\_scope. Notation "'exists' x : X , p" := (ex _ (fun x:X \Rightarrow p)) (at level 200, x ident, right associativity) : type\_scope.
```

We can use the usual set of tactics for manipulating existentials. For example, to prove an existential, we can apply the constructor ex\_intro. Since the premise of ex\_intro involves

a variable (*witness*) that does not appear in its conclusion, we need to explicitly give its value when we use apply.

```
Example exists_example_1 : \exists n, n + (n × n) = 6. 
Proof. 
apply ex_intro with (witness:=2). 
reflexivity. Qed.
```

Note that we have to explicitly give the witness.

Or, instead of writing apply ex\_intro with (witness:=e) all the time, we can use the convenient shorthand  $\exists$  e, which means the same thing.

```
Example exists_example_1' : \exists n, n + (n \times n) = 6.

Proof.

\exists 2.

reflexivity. Qed.
```

Conversely, if we have an existential hypothesis in the context, we can eliminate it with inversion. Note the use of the as... pattern to name the variable that Coq introduces to name the witness value and get evidence that the hypothesis holds for the witness. (If we don't explicitly choose one, Coq will just call it witness, which makes proofs confusing.)

```
Theorem exists_example_2 : \forall n, (\exists m, n = 4 + m) \rightarrow (\exists o, n = 2 + o).

Proof.

intros n H.

inversion H as [m \ Hm].

\exists (2 + m).

apply Hm. Qed.
```

Exercise: 1 star, optional (english\_exists) In English, what does the proposition ex nat (fun n = beautiful (S n)) | mean?

Exercise: 1 star (dist\_not\_exists) Prove that "P holds for all x" implies "there is no x for which P does not hold."

```
Theorem dist_not_exists : \forall (X:Type) (P: X \to \text{Prop}), (\forall x, P x) \to \neg (\exists x, \neg P x).

Proof.

Admitted.
```

Exercise: 3 stars, optional (not\_exists\_dist) (The other direction of this theorem requires the classical "law of the excluded middle".)

Theorem not\_exists\_dist :

```
excluded_middle \rightarrow \forall (X: \mathsf{Type}) \ (P: X \rightarrow \mathsf{Prop}), \neg \ (\exists \ x \ , \ \neg \ P \ x) \rightarrow (\forall \ x, \ P \ x). Proof.

Admitted.
```

Exercise: 2 stars (dist\_exists\_or) Prove that existential quantification distributes over disjunction.

```
Theorem dist_exists_or: \forall (X: \mathsf{Type}) (P \ Q: X \to \mathsf{Prop}), (\exists \ x, \ P \ x \lor \ Q \ x) \leftrightarrow (\exists \ x, \ P \ x) \lor (\exists \ x, \ Q \ x). Proof.

Admitted.
```

### 31.7 Equality

Even Coq's equality relation is not built in. It has (roughly) the following inductive definition.

```
Module MYEQUALITY.
```

```
\begin{array}{l} \text{Inductive } \textbf{eq} \ \{X : \texttt{Type}\} : X \to X \to \texttt{Prop} := \\ \text{refl\_equal} : \forall \ x, \ \textbf{eq} \ x \ x. \\ \text{Standard infix notation:} \\ \text{Notation } "\mathbf{x} = \mathbf{y}" := (\textbf{eq} \ x \ y) \\ & (\text{at level } 70, \ \text{no associativity}) \\ & : \ type\_scope. \end{array}
```

The definition of = is a bit subtle. The way to think about it is that, given a set X, it defines a *family* of propositions "x is equal to y," indexed by pairs of values (x and y) from X. There is just one way of constructing evidence for members of this family: applying the constructor refl\_equal to a type X and a value x: X yields evidence that x is equal to x.

**Exercise: 2 stars (leibniz\_equality)** The inductive definitions of equality corresponds to *Leibniz equality*: what we mean when we say "x and y are equal" is that every property on P that is true of x is also true of y.

```
Lemma leibniz_equality : \forall (X : Type) (x y: X), x = y \rightarrow \forall P : X \rightarrow \mathsf{Prop}, P x \rightarrow P y. Proof.

Admitted.
```

We can use refl\_equal to construct evidence that, for example, 2 = 2. Can we also use it to construct evidence that 1 + 1 = 2? Yes: indeed, it is the very same piece of evidence! The reason is that Coq treats as "the same" any two terms that are *convertible* according to a simple set of computation rules. These rules, which are similar to those used by Eval compute, include evaluation of function application, inlining of definitions, and simplification of matches.

```
Lemma four: 2 + 2 = 1 + 3.
Proof.
  apply refl_equal.
Qed.
```

The reflexivity tactic that we have used to prove equalities up to now is essentially just short-hand for apply reflequal.

End MYEQUALITY.

#### 31.8 Evidence-carrying booleans.

So far we've seen two different forms of equality predicates: **eq**, which produces a **Prop**, and the type-specific forms, like **beq\_nat**, that produce *boolean* values. The former are more convenient to reason about, but we've relied on the latter to let us use equality tests in *computations*. While it is straightforward to write lemmas (e.g. beq\_nat\_true and beq\_nat\_false) that connect the two forms, using these lemmas quickly gets tedious.

It turns out that we can get the benefits of both forms at once by using a construct called **sumbool**.

```
Inductive sumbool (A B : Prop) : Set := | left : A \rightarrow sumbool A B | right : B \rightarrow sumbool A B.
Notation "\{A\} + \{B\}" := (sumbool A B) : type\_scope.
```

Think of **sumbool** as being like the *boolean* type, but instead of its values being just true and false, they carry *evidence* of truth or falsity. This means that when we **destruct** them, we are left with the relevant evidence as a hypothesis – just as with **or**. (In fact, the definition of **sumbool** is almost the same as for **or**. The only difference is that values of **sumbool** are declared to be in **Set** rather than in **Prop**; this is a technical distinction that allows us to compute with them.)

Here's how we can define a sumbool for equality on nats

```
Theorem eq_nat_dec : \forall \ n \ m : \operatorname{nat}, \{n = m\} + \{n \neq m\}. Proof. intros n. induction n as [|n']. Case \ "n = 0". intros m.
```

```
destruct m as [|m'|].

SCase "m = 0".

left. reflexivity.

SCase "m = S m'".

right. intros contra. inversion contra.

Case "n = S n'".

intros m.

destruct m as [|m'|].

SCase "m = 0".

right. intros contra. inversion contra.

SCase "m = S m'".

destruct IHn' with (m := m') as [eq \mid neq].

left. apply f_equal. apply eq.

right. intros Heq. inversion Heq as [Heq']. apply neq. apply Heq'.

Defined.
```

Read as a theorem, this says that equality on **nat**s is decidable: that is, given two **nat** values, we can always produce either evidence that they are equal or evidence that they are not. Read computationally, eq\_nat\_dec takes two **nat** values and returns a **sumbool** constructed with left if they are equal and right if they are not; this result can be tested with a match or, better, with an if-then-else, just like a regular boolean. (Notice that we ended this proof with Defined rather than Qed. The only difference this makes is that the proof becomes transparent, meaning that its definition is available when Coq tries to do reductions, which is important for the computational interpretation.)

Here's a simple example illustrating the advantages of the **sumbool** form.

```
Definition override' \{X : \mathsf{Type}\}\ (f : \mathsf{nat} \to X)\ (k : \mathsf{nat})\ (x : X) : \mathsf{nat} \to X := \mathsf{fun}\ (k' : \mathsf{nat}) \Rightarrow \mathsf{if}\ \mathsf{eq\_nat\_dec}\ k\ k'\ \mathsf{then}\ x\ \mathsf{else}\ f\ k'.
Theorem override_same' : \forall\ (X : \mathsf{Type})\ x1\ k1\ k2\ (f : \mathsf{nat} \to X), f\ k1 = x1 \to (\mathsf{override}'\ f\ k1\ x1)\ k2 = f\ k2.
Proof.

intros X\ x1\ k1\ k2\ f. intros Hx1.

unfold override'.

destruct (eq_nat_dec k1\ k2). Case\ "k1 = k2".

rewrite \leftarrow\ e.

symmetry. apply Hx1.
Case\ "k1 <> k2".

reflexivity. Qed.
```

Compare this to the more laborious proof (in MoreCoq.v) for the version of override defined using beq\_nat, where we had to use the auxiliary lemma beq\_nat\_true to convert a fact about booleans to a Prop.

```
Exercise: 1 star (override_shadow') Theorem override_shadow': \forall (X:Type) \ x1 \ x2 \ k1 \ k2 \ (f: nat \rightarrow X), (override' (override' f \ k1 \ x2) \ k1 \ x1) \ k2 = (override' f \ k1 \ x1) \ k2. Proof.

Admitted.
```

#### 31.8.1 Inversion, Again (Advanced)

We've seen inversion used with both equality hypotheses and hypotheses about inductively defined propositions. Now that we've seen that these are actually the same thing, we're in a position to take a closer look at how inversion behaves...

In general, the inversion tactic

- takes a hypothesis H whose type P is inductively defined, and
- for each constructor C in P's definition,
  - generates a new subgoal in which we assume H was built with C,
  - adds the arguments (premises) of C to the context of the subgoal as extra hypotheses,
  - matches the conclusion (result type) of C against the current goal and calculates a set of equalities that must hold in order for C to be applicable,
  - adds these equalities to the context (and, for convenience, rewrites them in the goal), and
  - if the equalities are not satisfiable (e.g., they involve things like  $S\ n=O$ ), immediately solves the subgoal.

*Example*: If we invert a hypothesis built with **or**, there are two constructors, so two subgoals get generated. The conclusion (result type) of the constructor  $(P \lor Q)$  doesn't place any restrictions on the form of P or Q, so we don't get any extra equalities in the context of the subgoal.

Example: If we invert a hypothesis built with **and**, there is only one constructor, so only one subgoal gets generated. Again, the conclusion (result type) of the constructor ( $P \wedge Q$ ) doesn't place any restrictions on the form of P or Q, so we don't get any extra equalities in the context of the subgoal. The constructor does have two arguments, though, and these can be seen in the context in the subgoal.

Example: If we invert a hypothesis built with **eq**, there is again only one constructor, so only one subgoal gets generated. Now, though, the form of the **refl\_equal** constructor does give us some extra information: it tells us that the two arguments to **eq** must be the same! The inversion tactic adds this fact to the context.

Exercise: 1 star, optional (dist\_and\_or\_eq\_implies\_and) Lemma dist\_and\_or\_eq\_implies\_and :  $\forall P Q R$ ,

```
Proof.
P \wedge (Q \vee R) \wedge Q = R \rightarrow P \wedge Q.
Admitted.
```

#### 31.9 Additional Exercises

Exercise: 3 stars (all\_forallb) Inductively define a property all of lists, parameterized by a type X and a property  $P: X \to Prop$ , such that all X P I asserts that P is true for every element of the list I.

Recall the function forallb, from the exercise forall\_exists\_challenge in chapter Poly:

```
Fixpoint forallb \{X: \mathsf{Type}\}\ (test: X \to \mathbf{bool})\ (l: \mathsf{list}\ X): \mathbf{bool} := \mathsf{match}\ l \ \mathsf{with} |\ [] \Rightarrow \mathsf{true} |\ x::\ l' \Rightarrow \mathsf{andb}\ (test\ x)\ (\mathsf{forallb}\ test\ l') end.
```

Using the property **all**, write down a specification for **forallb**, and prove that it satisfies the specification. Try to make your specification as precise as possible.

Are there any important properties of the function forallb which are not captured by your specification?

Exercise: 4 stars, advanced (filter\_challenge) One of the main purposes of Coq is to prove that programs match their specifications. To this end, let's prove that our definition of filter matches a specification. Here is the specification, written out informally in English.

Suppose we have a set X, a function test:  $X \rightarrow bool$ , and a list I of type list X. Suppose further that I is an "in-order merge" of two lists, l1 and l2, such that every item in l1 satisfies test and no item in l2 satisfies test. Then filter test l=l1.

A list I is an "in-order merge" of l1 and l2 if it contains all the same elements as l1 and l2, in the same order as l1 and l2, but possibly interleaved. For example, 1,4,6,2,3 is an in-order merge of 1,6,2 and 4,3. Your job is to translate this specification into a Coq theorem and prove it. (Hint: You'll need to begin by defining what it means for one list to be a merge of two others. Do this with an inductive relation, not a Fixpoint.)

Exercise: 5 stars, advanced, optional (filter\_challenge\_2) A different way to formally characterize the behavior of filter goes like this: Among all subsequences of I with the property that test evaluates to true on all their members, filter test I is the longest. Express this claim formally and prove it.

Exercise: 4 stars, advanced (no\_repeats) The following inductively defined proposition...

```
Inductive appears_in \{X: \texttt{Type}\}\ (a:X) : \texttt{list}\ X \to \texttt{Prop} := | \texttt{ai\_here} : \forall\ l, \texttt{appears\_in}\ a\ (a::l) | \texttt{ai\_later} : \forall\ b\ l, \texttt{appears\_in}\ a\ l \to \texttt{appears\_in}\ a\ (b::l).
```

...gives us a precise way of saying that a value **a** appears at least once as a member of a list l.

Here's a pair of warm-ups about **appears\_in**.

```
 \begin{array}{l} \mathsf{Lemma\ appears\_in\_app}: \ \forall \ (X : \mathsf{Type}) \ (xs \ ys : \ \mathsf{list} \ X) \ (x : X), \\ & \mathsf{appears\_in} \ x \ (xs \ ++ \ ys) \to \mathsf{appears\_in} \ x \ xs \ \lor \ \mathsf{appears\_in} \ x \ ys. \\ \mathsf{Proof}. \\ & Admitted. \\ \mathsf{Lemma\ app\_appears\_in}: \ \forall \ (X : \mathsf{Type}) \ (xs \ ys : \ \mathsf{list} \ X) \ (x : X), \\ & \mathsf{appears\_in} \ x \ xs \ \lor \ \mathsf{appears\_in} \ x \ ys \to \ \mathsf{appears\_in} \ x \ (xs \ ++ \ ys). \\ \mathsf{Proof}. \end{array}
```

Now use **appears\_in** to define a proposition *disjoint* X l1 l2, which should be provable exactly when l1 and l2 are lists (with elements of type X) that have no elements in common.

Next, use **appears\_in** to define an inductive proposition  $no\_repeats \ X \ I$ , which should be provable exactly when I is a list (with elements of type X) where every member is different from every other. For example,  $no\_repeats \ nat \ [1,2,3,4]$  and  $no\_repeats \ bool \ []$  should be provable, while  $no\_repeats \ nat \ [1,2,1]$  and  $no\_repeats \ bool \ []$  true,true should not be.

Finally, state and prove one or more interesting theorems relating disjoint,  $no\_repeats$  and ++ (list append).

Admitted.

**Exercise: 3 stars (nostutter)** Formulating inductive definitions of predicates is an important skill you'll need in this course. Try to solve this exercise without any help at all (except from your study group partner, if you have one).

We say that a list of numbers "stutters" if it repeats the same number consecutively. The predicate "**nostutter mylist**" means that **mylist** does not stutter. Formulate an inductive definition for **nostutter**. (This is different from the *no\_repeats* predicate in the exercise above; the sequence 1,4,1 repeats but does not stutter.)

```
Inductive nostutter: list nat \rightarrow Prop :=
```

.

Make sure each of these tests succeeds, but you are free to change the proof if the given one doesn't work for you. Your definition might be different from mine and still correct, in which case the examples might need a different proof.

The suggested proofs for the examples (in comments) use a number of tactics we haven't talked about, to try to make them robust with respect to different possible ways of defining **nostutter**. You should be able to just uncomment and use them as-is, but if you prefer you can also prove each example with more basic tactics.

```
Example test_nostutter_1: nostutter [3;1;4;1;5;6]. 
 Admitted.

Example test_nostutter_2: nostutter []. 
 Admitted.

Example test_nostutter_3: nostutter [5]. 
 Admitted.

Example test_nostutter_4: not (nostutter [3;1;1;4]). 
 Admitted.
```

Exercise: 4 stars, advanced (pigeonhole principle) The "pigeonhole principle" states a basic fact about counting: if you distribute more than n items into n pigeonholes, some pigeonhole must contain at least two items. As is often the case, this apparently trivial fact about numbers requires non-trivial machinery to prove, but we now have enough...

First a pair of useful lemmas (we already proved these for lists of naturals, but not for arbitrary lists).

```
Lemma app_length : \forall (X:Type) (l1\ l2: list X), length (l1\ ++\ l2) = length l1\ + length l2. Proof.

Admitted.

Lemma appears_in_app_split : \forall (X:Type) (x:X) (l:list X), appears_in x\ l \rightarrow \exists\ l1, \exists\ l2, l=l1\ ++\ (x::l2).

Proof.

Admitted.
```

Now define a predicate **repeats** (analogous to  $no\_repeats$  in the exercise above), such that **repeats** X I asserts that I contains at least one repeated element (of type X).

```
Inductive repeats \{X: Type\}: list X \rightarrow Prop :=
```

Now here's a way to formalize the pigeonhole principle. List l2 represents a list of pigeonhole labels, and list l1 represents an assignment of items to labels: if there are more items than labels, at least two items must have the same label. You will almost certainly need to use the excluded\_middle hypothesis.

```
Theorem pigeonhole_principle: \forall \ (X: \texttt{Type}) \ (l1 \ l2: \texttt{list} \ X), excluded_middle \rightarrow (\forall \ x, \ \texttt{appears\_in} \ x \ l1 \ \rightarrow \ \texttt{appears\_in} \ x \ l2) \rightarrow length l2 < \texttt{length} \ l1 \rightarrow repeats l1. Proof. intros X \ l1. induction l1. Admitted.
```

# Chapter 32

# Library Prop

### 32.1 Prop: Propositions and Evidence

Require Export MoreCoq.

In previous chapters, we have seen many examples of factual claims (*propositions*) and ways of presenting evidence of their truth (*proofs*). In particular, we have worked extensively with *equality propositions* of the form e1 = e2, with implications ( $P \rightarrow Q$ ), and with quantified propositions ( $\forall x, P$ ).

This chapter will take us on a first tour of the propositional (logical) side of Coq. In particular, we will expand our repertoire of primitive propositions to include *user-defined* propositions, not just equality propositions (which are more-or-less "built in" to Coq).

#### 32.2 Inductively Defined Propositions

As a running example, let's define a simple property of natural numbers – we'll call it "beautiful."

Informally, a number is **beautiful** if it is 0, 3, 5, or the sum of two **beautiful** numbers. More pedantically, we can define **beautiful** numbers by giving four rules:

- Rule b\_0: The number 0 is **beautiful**.
- Rule b\_3: The number 3 is **beautiful**.
- Rule b\_5: The number 5 is **beautiful**.
- Rule b\_sum: If n and m are both beautiful, then so is their sum.

We will see many definitions like this one during the rest of the course, and for purposes of informal discussions, it is helpful to have a lightweight notation that makes them easy to read and write. *Inference rules* are one such notation:

(b<sub>0</sub>) beautiful 0

(b<sub>3</sub>) beautiful 3

(b<sub>5</sub>) beautiful 5 beautiful n beautiful m

```
(b_sum) beautiful (n+m)
```

Each of the textual rules above is reformatted here as an inference rule; the intended reading is that, if the *premises* above the line all hold, then the *conclusion* below the line follows. For example, the rule b\_sum says that, if n and m are both **beautiful** numbers, then it follows that n+m is **beautiful** too. If a rule has no premises above the line, then its conclusion hold unconditionally.

These rules define the property **beautiful**. That is, if we want to convince someone that some particular number is **beautiful**, our argument must be based on these rules. For a simple example, suppose we claim that the number 5 is **beautiful**. To support this claim, we just need to point out that rule b\_5 says so. Or, if we want to claim that 8 is **beautiful**, we can support our claim by first observing that 3 and 5 are both **beautiful** (by rules b\_3 and b\_5) and then pointing out that their sum, 8, is therefore **beautiful** by rule b\_sum. This argument can be expressed graphically with the following proof tree:

```
(b_{-}3) — (b_{-}5) beautiful 3 beautiful 5
```

(b\_sum) beautiful 8 Of course, there are other ways of using these rules to argue that 8 is **beautiful**, for instance:

```
(b_{-}5) — (b_{-}3) beautiful 5 beautiful 3
```

(b\_sum) beautiful 8

Exercise: 1 star (varieties\_of\_beauty) How many different ways are there to show that 8 is beautiful?

In Coq, we can express the definition of **beautiful** as follows:

```
Inductive beautiful: nat \rightarrow Prop := b_0: beautiful 0
| b_3: beautiful 3
| b_5: beautiful 5
```

 $\mid b\_sum : \forall n \ m$ , beautiful  $n \to beautiful \ m \to beautiful \ (n+m)$ .

The first line declares that **beautiful** is a proposition – or, more formally, a family of propositions "indexed by" natural numbers. (That is, for each number n, the claim that "n

is **beautiful**" is a proposition.) Such a family of propositions is often called a *property* of numbers. Each of the remaining lines embodies one of the rules for **beautiful** numbers.

The rules introduced this way have the same status as proven theorems; that is, they are true axiomatically. So we can use Coq's apply tactic with the rule names to prove that particular numbers are **beautiful**.

```
Theorem three_is_beautiful: beautiful 3.
Proof.
   apply b<sub>3</sub>.
Qed.
Theorem eight_is_beautiful: beautiful 8.
Proof.
   apply b_{sum} with (n:=3) (m:=5).
   apply b<sub>3</sub>.
   apply b<sub>-</sub>5.
Qed.
    As you would expect, we can also prove theorems that have hypotheses about beautiful.
Theorem beautiful_plus_eight: \forall n, beautiful n \rightarrow beautiful (8+n).
Proof.
  intros n B.
  apply b_sum with (n:=8) (m:=n).
  apply eight_is_beautiful.
  apply B.
Qed.
Exercise: 2 stars (b_timesm) Theorem b_timesm: \forall n \ m, beautiful n \rightarrow beautiful
(m \times n).
Proof.
   Admitted.
```

#### 32.2.1 Induction Over Evidence

Besides *constructing* evidence that numbers are beautiful, we can also *reason about* such evidence.

The fact that we introduced **beautiful** with an Inductive declaration tells Coq not only that the constructors b\_0, b\_3, b\_5 and b\_sum are ways to build evidence, but also that these two constructors are the *only* ways to build evidence that numbers are beautiful.

In other words, if someone gives us evidence E for the assertion **beautiful** n, then we know that E must have one of four shapes:

• *E* is b\_0 (and n is O),

• *E* is b\_3 (and n is 3),

- *E* is **b\_5** (and **n** is 5), or
- E is  $b_{-sum}$  n1 n2 E1 E2 (and n is n1+n2, where E1 is evidence that n1 is beautiful and E2 is evidence that n2 is beautiful).

This permits us to *analyze* any hypothesis of the form **beautiful** n to see how it was constructed, using the tactics we already know. In particular, we can use the **induction** tactic that we have already seen for reasoning about inductively defined *data* to reason about inductively defined *evidence*.

To illustrate this, let's define another property of numbers:

```
\begin{array}{l} \text{Inductive gorgeous}: \mathbf{nat} \to \mathtt{Prop} := \\ \mathsf{g\_0}: \mathbf{gorgeous} \ 0 \\ \mid \mathsf{g\_plus3}: \ \forall \ n, \, \mathbf{gorgeous} \ n \to \mathbf{gorgeous} \ (3+n) \\ \mid \mathsf{g\_plus5}: \ \forall \ n, \, \mathbf{gorgeous} \ n \to \mathbf{gorgeous} \ (5+n). \end{array}
```

Exercise: 1 star (gorgeous\_tree) Write out the definition of gorgeous numbers using inference rule notation.

```
Exercise: 1 star (gorgeous_plus13) Theorem gorgeous_plus13: \forall n, gorgeous n \to \text{gorgeous}\ (13+n). Proof.

Admitted.
```

It seems intuitively obvious that, although **gorgeous** and **beautiful** are presented using slightly different rules, they are actually the same property in the sense that they are true of the same numbers. Indeed, we can prove this.

```
Theorem gorgeous__beautiful : \forall n, gorgeous n \rightarrow beautiful n.

Proof.

intros n H.

induction H as [|n'|n'].

Case "g_0".

apply b_0.

Case "g_plus3".

apply b_sum. apply b_3.

apply IHgorgeous.

Case "g_plus5".

apply b_sum. apply b_5. apply IHgorgeous.

Qed.
```

Notice that the argument proceeds by induction on the evidence H!

Let's see what happens if we try to prove this by induction on  ${\sf n}$  instead of induction on the evidence H.

```
Theorem gorgeous_beautiful_FAILED : \forall n, gorgeous n \rightarrow beautiful n.

Proof.

intros. induction n as [\mid n'].

Case "n = 0". apply b_0.

Case "n = S n'". Abort.
```

The problem here is that doing induction on n doesn't yield a useful induction hypothesis. Knowing how the property we are interested in behaves on the predecessor of n doesn't help us prove that it holds for n. Instead, we would like to be able to have induction hypotheses that mention other numbers, such as n - 3 and n - 5. This is given precisely by the shape of the constructors for **gorgeous**.

```
Exercise: 2 stars (gorgeous_sum) Theorem gorgeous_sum : \forall n m, gorgeous n \to \text{gorgeous } m \to \text{gorgeous } (n+m).

Proof.

Admitted.

Exercise: 3 stars, advanced (beautiful__gorgeous) Theorem beautiful__gorgeous : \forall n, beautiful n \to \text{gorgeous } n.

Proof.

Admitted.

\square
```

Exercise: 3 stars, optional (g\_times2) Prove the g\_times2 theorem below without using gorgeous\_beautiful. You might find the following helper lemma useful.

```
Lemma helper_g_times2 : \forall \ x \ y \ z, \ x + (z + y) = z + x + y. Proof.

Admitted.

Theorem g_times2: \forall \ n, \ \mathbf{gorgeous} \ n \to \mathbf{gorgeous} \ (2 \times n). Proof.

intros n \ H. \ \mathbf{simpl.}

induction H.

Admitted.
```

#### 32.2.2 From Boolean Functions to Propositions

In chapter Basics we defined a *function* evenb that tests a number for evenness, yielding true if so. We can use this function to define the *proposition* that some number n is even:

```
Definition even (n:nat): Prop := evenb n = true.
```

That is, we can define "n is even" to mean "the function evenb returns true when applied to n."

Note that here we have given a name to a proposition using a **Definition**, just as we have given names to expressions of other sorts. This isn't a fundamentally new kind of proposition; it is still just an equality.

Another alternative is to define the concept of evenness directly. Instead of going via the evenb function ("a number is even if a certain computation yields true"), we can say what the concept of evenness means by giving two different ways of presenting evidence that a number is even.

```
Inductive ev : nat \rightarrow Prop := \mid ev_0 : ev 0 \mid ev_SS : \forall n:nat, ev n \rightarrow ev (S (S n)).
```

This definition says that there are two ways to give evidence that a number m is even. First, 0 is even, and  $ev_0$  is evidence for this. Second, if m = S(Sn) for some n and we can give evidence e that n is even, then m is also even, and  $ev_SSn$  e is the evidence.

```
Exercise: 1 star (double_even) Theorem double_even : \forall n, ev (double n).

Proof.

Admitted.
```

#### Discussion: Computational vs. Inductive Definitions

We have seen that the proposition "n is even" can be phrased in two different ways – indirectly, via a boolean testing function evenb, or directly, by inductively describing what constitutes evidence for evenness. These two ways of defining evenness are about equally easy to state and work with. Which we choose is basically a question of taste.

However, for many other properties of interest, the direct inductive definition is preferable, since writing a testing function may be awkward or even impossible.

One such property is **beautiful**. This is a perfectly sensible definition of a set of numbers, but we cannot translate its definition directly into a Coq Fixpoint (or into a recursive function in any other common programming language). We might be able to find a clever way of testing this property using a Fixpoint (indeed, it is not too hard to find one in this case), but in general this could require arbitrarily deep thinking. In fact, if the property we are

interested in is uncomputable, then we cannot define it as a Fixpoint no matter how hard we try, because Coq requires that all Fixpoints correspond to terminating computations.

On the other hand, writing an inductive definition of what it means to give evidence for the property **beautiful** is straightforward.

Exercise: 1 star (ev\_even) Here is a proof that the inductive definition of evenness implies the computational one.

```
Theorem ev__even : \forall n, ev n \rightarrow even n.

Proof.

intros n E. induction E as [\mid n' E'].

Case "E = ev_0".

unfold even. reflexivity.

Case "E = ev_SS n' E'".

unfold even. apply IHE'.

Qed.
```

Could this proof also be carried out by induction on n instead of E? If not, why not?

The induction principle for inductively defined propositions does not follow quite the same form as that of inductively defined sets. For now, you can take the intuitive view that induction on evidence  $\mathbf{ev}$   $\mathbf{n}$  is similar to induction on  $\mathbf{n}$ , but restricts our attention to only those numbers for which evidence  $\mathbf{ev}$   $\mathbf{n}$  could be generated. We'll look at the induction principle of  $\mathbf{ev}$  in more depth below, to explain what's really going on.

**Exercise:** 1 star (l\_fails) The following proof attempt will not succeed. Theorem 1: forall n, ev n. Proof. intros n. induction n. Case "O". simpl. apply ev\_0. Case "S". ... Intuitively, we expect the proof to fail because not every number is even. However, what exactly causes the proof to fail?

Exercise: 2 stars (ev\_sum) Here's another exercise requiring induction.

```
Theorem ev_sum : \forall n m, ev n \rightarrow ev m \rightarrow ev (n+m). Proof. Admitted.
```

#### 32.2.3 *Inversion* on Evidence

Another situation where we want to analyze evidence for evenness is when proving that, if n is even, then  $pred\ (pred\ n)$  is too. In this case, we don't need to do an inductive proof. The

right tactic turns out to be inversion.

```
Theorem ev_minus2: \forall n, ev n \rightarrow ev (pred (pred n)). Proof. intros n E. inversion E as [\mid n' E']. Case \ "E = ev_0". simpl. apply ev_0. Case \ "E = ev_SS \ n' E'". simpl. apply E'. Qed.
```

Exercise: 1 star, optional (ev\_minus2\_n) What happens if we try to use destruct on n instead of inversion on E?

П

Another example, in which inversion helps narrow down to the relevant cases.

```
Theorem SSev_even: \forall n, ev (S(Sn)) \rightarrow ev n.
Proof.
intros n E.
inversion E as [|n' E'|].
apply E'. Qed.
```

These uses of inversion may seem a bit mysterious at first. Until now, we've only used inversion on equality propositions, to utilize injectivity of constructors or to discriminate between different constructors. But we see here that inversion can also be applied to analyzing evidence for inductively defined propositions.

(You might also expect that **destruct** would be a more suitable tactic to use here. Indeed, it is possible to use **destruct**, but it often throws away useful information, and the *eqn*: qualifier doesn't help much in this case.)

Here's how inversion works in general. Suppose the name I refers to an assumption P in the current context, where P has been defined by an Inductive declaration. Then, for each of the constructors of P, inversion I generates a subgoal in which I has been replaced by the exact, specific conditions under which this constructor could have been used to prove P. Some of these subgoals will be self-contradictory; inversion throws these away. The ones that are left represent the cases that must be proved to establish the original goal.

In this particular case, the <code>inversion</code> analyzed the construction ev (S(n)), determined that this could only have been constructed using  $ev_SS$ , and generated a new subgoal with the arguments of that constructor as new hypotheses. (It also produced an auxiliary equality, which happens to be useless here.) We'll begin exploring this more general behavior of inversion in what follows.

```
Exercise: 1 star (inversion_practice) Theorem SSSSev_even : \forall n, ev (S (S (S n))) \rightarrow ev n.

Proof.
```

Admitted.

The inversion tactic can also be used to derive goals by showing the absurdity of a hypothesis.

#### Theorem even5\_nonsense:

```
ev 5 \rightarrow 2 + 2 = 9.
Proof.
Admitted.
```

Exercise: 3 stars, advanced (ev\_ev\_ev) Finding the appropriate thing to do induction on is a bit tricky here:

```
Theorem ev_ev__ev : \forall n \ m, ev (n+m) \rightarrow ev n \rightarrow ev m. Proof. Admitted.
```

Exercise: 3 stars, optional (ev\_plus\_plus) Here's an exercise that just requires applying existing lemmas. No induction or even case analysis is needed, but some of the rewriting may be tedious.

```
Theorem ev_plus_plus : \forall n \ m \ p, ev (n+m) \rightarrow ev (n+p) \rightarrow ev (m+p). Proof.

Admitted.
```

## 32.3 Additional Exercises

Exercise: 4 stars (palindromes) A palindrome is a sequence that reads the same backwards as forwards.

• Define an inductive proposition *pal* on **list** X that captures what it means to be a palindrome. (Hint: You'll need three cases. Your definition should be based on the structure of the list; just having a single constructor

c : for all l, l = rev l -> pal l may seem obvious, but will not work very well.)

- Prove that forall l, pal (l ++ rev l).
- Prove that for all l, pal  $l \rightarrow l = rev l$ .

Exercise: 5 stars, optional (palindrome\_converse) Using your definition of pal from the previous exercise, prove that for all l, l = rev l -> pal l.

**Exercise:** 4 stars, advanced (subsequence) A list is a *subsequence* of another list if all of the elements in the first list occur in the same order in the second list, possibly with some extra elements in between. For example, 1,2,3 is a subsequence of each of the lists 1,2,3 1,1,1,2,2,3 1,2,7,3 5,6,1,9,9,2,7,3,8 but it is *not* a subsequence of any of the lists 1,2 1,3

- Define an inductive proposition *subseq* on **list nat** that captures what it means to be a subsequence. (Hint: You'll need three cases.)
- Prove that subsequence is reflexive, that is, any list is a subsequence of itself.
- Prove that for any lists l1, l2, and l3, if l1 is a subsequence of l2, then l1 is also a subsequence of l2 ++ l3.
- (Optional, harder) Prove that subsequence is transitive that is, if l1 is a subsequence of l2 and l2 is a subsequence of l3, then l1 is a subsequence of l3. Hint: choose your induction carefully!

**Exercise: 2 stars, optional (R\_provability)** Suppose we give Coq the following definition: Inductive R: nat -> list nat -> Prop :=  $| c1 : R \ 0 \ \square \ | c2 :$  forall n l, R n l -> R (S n) (n:: l) | c3 : forall n l, R (S n) l -> R n l. Which of the following propositions are provable?

• R 2 [1,0]

5,6,2,1,7,3,8

- R 1 [1,2,1,0]
- R 6 [3,2,1,0]

## Chapter 33

# Library MoreProp

## 33.1 MoreProp: More about Propositions and Evidence

Require Export "Prop".

#### 33.2 Relations

A proposition parameterized by a number (such as **ev** or **beautiful**) can be thought of as a *property* – i.e., it defines a subset of **nat**, namely those numbers for which the proposition is provable. In the same way, a two-argument proposition can be thought of as a *relation* – i.e., it defines a set of pairs for which the proposition is provable.

#### Module LEMODULE.

One useful example is the "less than or equal to" relation on numbers.

The following definition should be fairly intuitive. It says that there are two ways to give evidence that one number is less than or equal to another: either observe that they are the same number, or give evidence that the first is less than or equal to the predecessor of the second.

```
Inductive \mathbf{le}: \mathbf{nat} \to \mathbf{nat} \to \mathsf{Prop}:= \ \mid \mathsf{le}_{-}\mathsf{n}: \ \forall \ n, \ \mathsf{le} \ n \ n \ \mid \mathsf{le}_{-}\mathsf{S}: \ \forall \ n \ m, \ (\mathsf{le} \ n \ m) \to (\mathsf{le} \ n \ (\mathsf{S} \ m)). Notation "m <= n" := (\mathsf{le} \ m \ n).
```

Proofs of facts about  $\leq$  using the constructors le\_n and le\_S follow the same patterns as proofs about properties, like **ev** in chapter Prop. We can apply the constructors to prove  $\leq$  goals (e.g., to show that 3 <= 3 or 3 <= 6), and we can use tactics like **inversion** to extract information from  $\leq$  hypotheses in the context (e.g., to prove that  $(2 \leq 1) \rightarrow 2 + 2 = 5$ .)

Here are some sanity checks on the definition. (Notice that, although these are the same kind of simple "unit tests" as we gave for the testing functions we wrote in the first few

lectures, we must construct their proofs explicitly – simpl and reflexivity don't do the job, because the proofs aren't just a matter of simplifying computations.)

```
Theorem test_le1:
  3 < 3.
Proof.
  apply le_n. Qed.
Theorem test_le2:
  3 \le 6.
Proof.
  apply le_S. apply le_S. apply le_S. apply le_n. Qed.
Theorem test_le3:
  (2 < 1) \rightarrow 2 + 2 = 5.
Proof.
  intros H. inversion H. inversion H2. Qed.
   The "strictly less than" relation n < m can now be defined in terms of le.
End LEMODULE.
Definition It (n m: nat) := le (S n) m.
Notation "m < n" := (It m \ n).
   Here are a few more simple relations on numbers:
Inductive square_of : nat \rightarrow nat \rightarrow Prop :=
  sq: \forall n:nat, square\_of n (n \times n).
Inductive next_nat(n:nat): nat \rightarrow Prop :=
  \mid nn : next_nat n \in n.
Inductive next\_even (n:nat) : nat \rightarrow Prop :=
   ne_1: ev (S n) \rightarrow next\_even n (S n)
  | ne_2 : ev (S(S n)) \rightarrow next_even n(S(S n)).
```

Exercise: 2 stars (total\_relation) Define an inductive binary relation total\_relation that holds between every pair of natural numbers.

Exercise: 2 stars (empty\_relation) Define an inductive binary relation empty\_relation (on numbers) that never holds.

Exercise: 2 stars, optional (le\_exercises) Here are a number of facts about the  $\leq$  and < relations that we are going to need later in the course. The proofs make good practice exercises.

```
Lemma le_trans : \forall m \ n \ o, m \le n \to n \le o \to m \le o.
Proof.
    Admitted.
Theorem O_{le_n} : \forall n,
  0 \leq n.
Proof.
    Admitted.
Theorem n_le_m_Sn_le_Sm : \forall n m,
   n \leq m \rightarrow S \ n \leq S \ m.
Proof.
    Admitted.
Theorem Sn_{e}Sm_{n}l_{e}Sm_{n}l_{e}m : \forall n m,
   S n \leq S m \rightarrow n \leq m.
Proof.
    Admitted.
Theorem le_plus_l : \forall a \ b,
   a \leq a + b.
Proof.
    Admitted.
Theorem plus_lt: \forall n1 \ n2 \ m,
  n1 + n2 < m \rightarrow
   n1 < m \land n2 < m.
Proof.
 unfold lt.
    Admitted.
Theorem lt_S : \forall n m,
   n < m \rightarrow
   n < S m.
Proof.
    Admitted.
Theorem ble_nat_true : \forall n m,
   ble_nat n m = true \rightarrow n \leq m.
Proof.
    Admitted.
Theorem le_ble_nat : \forall n m,
   n \leq m \rightarrow
  ble_nat n m = true.
Proof.
    Admitted.
```

Theorem ble\_nat\_true\_trans :  $\forall n m o$ ,

```
ble_nat n m = true \rightarrow ble_nat m o = true \rightarrow ble_nat n o = true. Proof.
```

Admitted.

#### Exercise: 3 stars (R\_provability) Module R.

We can define three-place relations, four-place relations, etc., in just the same way as binary relations. For example, consider the following three-place relation on numbers:

```
Inductive \mathbf{R}: \mathbf{nat} \to \mathbf{nat} \to \mathbf{nat} \to \mathbf{Prop}:= \ \mid \mathbf{c1}: \ \mathbf{R} \ 0 \ 0 \ 0 \ \mid \mathbf{c2}: \ \forall \ m \ n \ o, \ \mathbf{R} \ m \ n \ o \to \mathbf{R} \ (\mathbf{S} \ m) \ n \ (\mathbf{S} \ o) \ \mid \mathbf{c3}: \ \forall \ m \ n \ o, \ \mathbf{R} \ m \ n \ o \to \mathbf{R} \ m \ (\mathbf{S} \ n) \ (\mathbf{S} \ o) \ \mid \mathbf{c4}: \ \forall \ m \ n \ o, \ \mathbf{R} \ (\mathbf{S} \ m) \ (\mathbf{S} \ n) \ (\mathbf{S} \ (\mathbf{S} \ o)) \to \mathbf{R} \ m \ n \ o \ \mid \mathbf{c5}: \ \forall \ m \ n \ o, \ \mathbf{R} \ m \ n \ o \to \mathbf{R} \ n \ m \ o.
```

- Which of the following propositions are provable?
  - R 1 1 2
  - R 2 2 6
- If we dropped constructor c5 from the definition of R, would the set of provable propositions change? Briefly (1 sentence) explain your answer.
- If we dropped constructor c4 from the definition of R, would the set of provable propositions change? Briefly (1 sentence) explain your answer.

Exercise: 3 stars, optional ( $R_{fact}$ ) Relation R actually encodes a familiar function. State and prove two theorems that formally connects the relation and the function. That is, if R m n o is true, what can we say about m, n, and o, and vice versa?

□ End R.

## 33.3 Programming with Propositions

A proposition is a statement expressing a factual claim, like "two plus two equals four." In Coq, propositions are written as expressions of type Prop. Although we haven't discussed this explicitly, we have already seen numerous examples.

```
Check (2 + 2 = 4).
Check (ble_nat 3 \ 2 = false).
Check (beautiful 8).
```

Both provable and unprovable claims are perfectly good propositions. Simply being a proposition is one thing; being provable is something else!

```
Check (2 + 2 = 5).
```

Check (beautiful 4).

Both 2 + 2 = 4 and 2 + 2 = 5 are legal expressions of type Prop.

We've mainly seen one place that propositions can appear in Coq: in Theorem (and Lemma and Example) declarations.

```
Theorem plus_2_2_is_4:
2 + 2 = 4.
Proof. reflexivity. Qed.
```

But they can be used in many other ways. For example, we have also seen that we can give a name to a proposition using a Definition, just as we have given names to expressions of other sorts.

```
Definition plus_fact : Prop := 2 + 2 = 4. Check plus_fact.
```

We can later use this name in any situation where a proposition is expected – for example, as the claim in a **Theorem** declaration.

```
Theorem plus_fact_is_true :
    plus_fact.
Proof. reflexivity. Qed.
```

We've seen several ways of constructing propositions.

- We can define a new proposition primitively using Inductive.
- Given two expressions e1 and e2 of the same type, we can form the proposition e1 = e2, which states that their values are equal.
- We can combine propositions using implication and quantification.

We have also seen parameterized propositions, such as even and beautiful.

```
Check (even 4). Check (even 3). Check even.
```

The type of even, i.e.,  $nat \rightarrow Prop$ , can be pronounced in three equivalent ways: (1) "even is a *function* from numbers to propositions," (2) "even is a *family* of propositions, indexed by a number n," or (3) "even is a *property* of numbers."

Propositions – including parameterized propositions – are first-class citizens in Coq. For example, we can define functions from numbers to propositions...

```
Definition between (n \ m \ o: nat) : Prop := andb (ble_nat <math>n \ o) (ble_nat o \ m) = true.
```

... and then partially apply them:

```
Definition teen : nat \rightarrow Prop := between 13 19.
```

We can even pass propositions – including parameterized propositions – as arguments to functions:

```
Definition true_for_zero (P:\mathbf{nat} \rightarrow \mathsf{Prop}): \mathsf{Prop} := P \ 0.
```

Here are two more examples of passing parameterized propositions as arguments to a function.

The first function, true\_for\_all\_numbers, takes a proposition P as argument and builds the proposition that P is true for all natural numbers.

```
Definition true_for_all_numbers (P:\mathbf{nat} \to \mathsf{Prop}) : \mathsf{Prop} := \forall \ n, \ P \ n.
```

The second, preserved\_by\_S, takes P and builds the proposition that, if P is true for some natural number n', then it is also true by the successor of n' – i.e. that P is preserved by successor:

```
Definition preserved_by_S (P:nat\rightarrowProp) : Prop := \forall n', P \ n' \rightarrow P \ (S \ n').
```

Finally, we can put these ingredients together to define a proposition stating that induction is valid for natural numbers:

```
 \begin{array}{l} {\sf Definition\ natural\_number\_induction\_valid: Prop:=} \\ \forall\ (P: {\sf nat} {\rightarrow} {\sf Prop}), \\ {\sf true\_for\_zero}\ P \to \\ {\sf preserved\_by\_S}\ P \to \\ {\sf true\_for\_all\_numbers}\ P. \end{array}
```

**Exercise:** 3 stars (combine\_odd\_even) Complete the definition of the combine\_odd\_even function below. It takes as arguments two properties of numbers *Podd* and *Peven*. As its result, it should return a new property P such that P n is equivalent to *Podd* n when n is odd, and equivalent to *Peven* n otherwise.

```
Definition combine_odd_even (Podd\ Peven: nat \rightarrow Prop): nat \rightarrow Prop := admit.
```

To test your definition, see whether you can prove the following facts:

Theorem combine\_odd\_even\_intro:

```
\forall \ (Podd \ Peven : \mathbf{nat} \to \mathtt{Prop}) \ (n : \mathbf{nat}), (oddb n = \mathsf{true} \to Podd \ n) \to (oddb n = \mathsf{false} \to Peven \ n) \to combine_odd_even Podd \ Peven \ n.
Proof.
```

Admitted.

```
Theorem combine_odd_even_elim_odd: \forall \ (Podd \ Peven : \mathbf{nat} \to \mathsf{Prop}) \ (n : \mathbf{nat}), \\ \mathsf{combine_odd_even} \ Podd \ Peven \ n \to \\ \mathsf{oddb} \ n = \mathsf{true} \to \\ Podd \ n. \mathsf{Proof}. Admitted. \mathsf{Theorem} \ \mathsf{combine_odd_even_elim_even} : \\ \forall \ (Podd \ Peven : \mathbf{nat} \to \mathsf{Prop}) \ (n : \mathbf{nat}), \\ \mathsf{combine_odd_even} \ Podd \ Peven \ n \to \\ \mathsf{oddb} \ n = \mathsf{false} \to \\ Peven \ n.} \mathsf{Proof}. \mathsf{Admitted}. \square
```

One more quick digression, for adventurous souls: if we can define parameterized propositions using Definition, then can we also define them using Fixpoint? Of course we can! However, this kind of "recursive parameterization" doesn't correspond to anything very familiar from everyday mathematics. The following exercise gives a slightly contrived example.

Exercise: 4 stars, optional (true\_upto\_n\_true\_everywhere) Define a recursive function  $true_upto_n_true_everywhere$  that makes  $true_upto_n_example$  work.

## Chapter 34

# Library MoreCoq

## 34.1 MoreCoq: More About Coq

Require Export Poly.

This chapter introduces several more Coq tactics that, together, allow us to prove many more theorems about the functional programs we are writing.

## 34.2 The apply Tactic

We often encounter situations where the goal to be proved is exactly the same as some hypothesis in the context or some previously proved lemma.

```
Theorem silly1: \forall (n \ m \ o \ p : \mathsf{nat}), n = m \rightarrow [n;o] = [n;p] \rightarrow [n;o] = [m;p]. Proof. intros n \ m \ o \ p \ eq1 \ eq2. rewrite \leftarrow eq1. apply eq2. Qed.
```

The apply tactic also works with *conditional* hypotheses and lemmas: if the statement being applied is an implication, then the premises of this implication will be added to the list of subgoals needing to be proved.

```
Theorem silly2 : \forall (n \ m \ o \ p : \mathbf{nat}), n = m \rightarrow (\forall \ (q \ r : \mathbf{nat}), \ q = r \rightarrow [q; o] = [r; p]) \rightarrow [n; o] = [m; p].
Proof.
intros n \ m \ o \ p \ eq1 \ eq2.
```

```
apply eq2. apply eq1. Qed.
```

You may find it instructive to experiment with this proof and see if there is a way to complete it using just rewrite instead of apply.

Typically, when we use apply H, the statement H will begin with a  $\forall$  binding some universal variables. When Coq matches the current goal against the conclusion of H, it will try to find appropriate values for these variables. For example, when we do apply eq2 in the following proof, the universal variable q in eq2 gets instantiated with n and r gets instantiated with m.

```
Theorem silly2a : \forall (n \ m : nat), (n,n) = (m,m) \rightarrow (\forall (q \ r : nat), (q,q) = (r,r) \rightarrow [q] = [r]) \rightarrow [n] = [m].

Proof.

intros n \ m \ eq1 \ eq2.

apply eq2. apply eq1. Qed.
```

Exercise: 2 stars, optional (silly\_ex) Complete the following proof without using simpl.

```
Theorem silly_ex :  (\forall \ n, \ \text{evenb} \ n = \text{true} \to \text{oddb} \ (\textbf{S} \ n) = \text{true}) \to \\ \text{evenb} \ 3 = \text{true} \to \\ \text{oddb} \ 4 = \text{true}. \\ \\ \text{Proof.} \\ Admitted. \\ \\ \square
```

To use the apply tactic, the (conclusion of the) fact being applied must match the goal exactly – for example, apply will not work if the left and right sides of the equality are swapped.

```
Theorem silly3_firsttry : \forall (n : nat),
true = beq_nat n 5 \rightarrow
beq_nat (S (S n)) 7 = true.
Proof.
intros n H.
simpl.
Abort.
```

In this case we can use the **symmetry** tactic, which switches the left and right sides of an equality in the goal.

```
Theorem silly3 : \forall (n: nat),

true = beq_nat n \ 5 \rightarrow

beq_nat (S \ (S \ n)) \ 7 = true.

Proof.
```

```
intros n H. symmetry. simpl. apply H. Qed.
```

Exercise: 3 stars (apply\_exercise1) Hint: you can use apply with previously defined lemmas, not just hypotheses in the context. Remember that SearchAbout is your friend.

```
Theorem rev_exercise1 : \forall (l l' : list nat), l = rev l' \rightarrow l' = rev l.

Proof.

Admitted.
```

Exercise: 1 star, optional (apply\_rewrite) Briefly explain the difference between the tactics apply and rewrite. Are there situations where both can usefully be applied?  $\Box$ 

## 34.3 The apply ... with ... Tactic

The following silly example uses two rewrites in a row to get from [a,b] to [e,f].

```
Example trans_eq_example : \forall (a b c d e f : \mathbf{nat}),  [a;b] = [c;d] \rightarrow \\ [c;d] = [e;f] \rightarrow \\ [a;b] = [e;f].  Proof.  \mathbf{nat} (a,b) = \mathbf{nat}
```

Since this is a common pattern, we might abstract it out as a lemma recording once and for all the fact that equality is transitive.

```
Theorem trans_eq : \forall (X:Type) (n m o : X),

n = m \rightarrow m = o \rightarrow n = o.

Proof.

intros X n m o eq1 eq2. rewrite \rightarrow eq1. rewrite \rightarrow eq2. reflexivity. Qed.
```

Now, we should be able to use trans\_eq to prove the above example. However, to do this we need a slight refinement of the apply tactic.

```
Example trans_eq_example' : \forall (a b c d e f : nat),

[a;b] = [c;d] \rightarrow

[c;d] = [e;f] \rightarrow

[a;b] = [e;f].

Proof.
```

```
intros a b c d e f eq1 eq2. apply trans_eq with (m:=[c;d]). apply eq1. apply eq2. Qed.
```

Actually, we usually don't have to include the name m in the with clause; Coq is often smart enough to figure out which instantiation we're giving. We could instead write: apply trans\_eq with [c,d].

```
Exercise: 3 stars, optional (apply_with_exercise) Example trans_eq_exercise : \forall (n m o p : \mathsf{nat}), m = (minustwo o) \rightarrow (n + p) = m \rightarrow (n + p) = (minustwo o). Proof. Admitted.
```

#### 34.4 The inversion tactic

Recall the definition of natural numbers: Inductive nat: Type := |O:nat|S:nat-> nat. It is clear from this definition that every number has one of two forms: either it is the constructor O or it is built by applying the constructor S to another number. But there is more here than meets the eye: implicit in the definition (and in our informal understanding of how datatype declarations work in other programming languages) are two other facts:

- The constructor S is *injective*. That is, the only way we can have S n = S m is if n = m.
- The constructors O and S are *disjoint*. That is, O is not equal to S n for any n.

Similar principles apply to all inductively defined types: all constructors are injective, and the values built from distinct constructors are never equal. For lists, the cons constructor is injective and nil is different from every non-empty list. For booleans, true and false are unequal. (Since neither true nor false take any arguments, their injectivity is not an issue.)

Coq provides a tactic called inversion that allows us to exploit these principles in proofs.

The inversion tactic is used like this. Suppose H is a hypothesis in the context (or a previously proven lemma) of the form c a1 a2 ... an = d b1 b2 ... bm for some constructors c and d and arguments a1 ... an and b1 ... bm. Then inversion H instructs Coq to "invert" this equality to extract the information it contains about these terms:

• If c and d are the same constructor, then we know, by the injectivity of this constructor, that a1 = b1, a2 = b2, etc.; inversion H adds these facts to the context, and tries to use them to rewrite the goal.

• If c and d are different constructors, then the hypothesis H is contradictory. That is, a false assumption has crept into the context, and this means that any goal whatsoever is provable! In this case, inversion H marks the current goal as completed and pops it off the goal stack.

The inversion tactic is probably easier to understand by seeing it in action than from general descriptions like the above. Below you will find example theorems that demonstrate the use of inversion and exercises to test your understanding.

```
Theorem eq_add_S: \forall (n m : nat),
      S n = S m \rightarrow
      n = m.
Proof.
  intros n m eq. inversion eq. reflexivity. Qed.
Theorem silly4: \forall (n \ m : nat),
      [n] = [m] \rightarrow
      n = m.
Proof.
  intros n o eq. inversion eq. reflexivity. Qed.
    As a convenience, the inversion tactic can also destruct equalities between complex
values, binding multiple variables as it goes.
Theorem silly5: \forall (n \ m \ o : nat),
      [n;m] = [o;o] \rightarrow
      [n] = [m].
Proof.
  intros n m o eq. inversion eq. reflexivity. Qed.
Exercise: 1 star (sillyex1) Example sillyex1: \forall (X : Type) (x \ y \ z : X) (l \ j : list \ X),
      x :: y :: l = z :: j \rightarrow
      y :: l = x :: j \rightarrow
Proof.
    Admitted.
Theorem silly6 : \forall (n : nat),
      S n = O \rightarrow
      2 + 2 = 5.
Proof.
  intros n contra. inversion contra. Qed.
Theorem silly 7: \forall (n \ m : nat),
      false = true \rightarrow
      [n] = [m].
```

Proof.

intros n m contra. inversion contra. Qed.

```
Exercise: 1 star (sillyex2) Example sillyex2 : \forall (X : Type) (x y z : X) (l j : list X), x :: y :: l = [] \rightarrow y :: l = z :: j \rightarrow x = z.

Proof.

Admitted.
```

While the injectivity of constructors allows us to reason  $\forall$   $(n \ m : nat)$ ,  $S \ n = S \ m \rightarrow n = m$ , the reverse direction of the implication is an instance of a more general fact about constructors and functions, which we will often find useful:

```
Theorem f_equal : \forall (A \ B : Type) (f: A \to B) (x \ y: A), x = y \to f \ x = f \ y. Proof. intros A \ B \ f \ x \ y \ eq. rewrite eq. reflexivity. Qed.
```

Here's another illustration of inversion. This is a slightly roundabout way of stating a fact that we have already proved above. The extra equalities force us to do a little more equational reasoning and exercise some of the tactics we've seen recently.

```
Theorem length_snoc': \forall (X: \mathsf{Type}) \ (v:X) (l: \mathsf{list}\ X) \ (n: \mathsf{nat}), length l = n \to \mathsf{length} \ (\mathsf{snoc}\ l\ v) = \mathsf{S}\ n. Proof.

intros X\ v\ l. induction l\ \mathsf{as}\ [|\ v'\ l']. Case\ "l = []". intros n\ eq. rewrite \leftarrow eq. reflexivity. Case\ "l = v':: l'". intros n\ eq. simpl. destruct n\ \mathsf{as}\ [|\ n']. SCase\ "n = 0". inversion eq. SCase\ "n = \mathsf{S}\ n'". apply f_equal. apply IHl'. inversion eq. reflexivity. Qed.
```

Exercise: 2 stars, optional (practice) A couple more nontrivial but not-too-complicated proofs to work together in class, or for you to work as exercises. They may involve applying lemmas from earlier lectures or homeworks.

```
Theorem beq_nat_0_l: \forall n, beq_nat 0 \ n = true \rightarrow n = 0. Proof. Admitted. Theorem beq_nat_0_r: \forall n, beq_nat n \ 0 = true \rightarrow n = 0. Proof.
```

## 34.5 Using Tactics on Hypotheses

By default, most tactics work on the goal formula and leave the context unchanged. However, most tactics also have a variant that performs a similar operation on a statement in the context.

For example, the tactic simpline H performs simplification in the hypothesis named H in the context.

```
Theorem S_inj : \forall (n \ m : \mathbf{nat}) \ (b : \mathbf{bool}), beq_nat (\mathbf{S} \ n) \ (\mathbf{S} \ m) = b \rightarrow beq_nat n \ m = b.

Proof.

intros n \ m \ b \ H. simpl in H. apply H. Qed.
```

Similarly, the tactic apply L in H matches some conditional statement L (of the form  $L1 \to L2$ , say) against a hypothesis H in the context. However, unlike ordinary apply (which rewrites a goal matching L2 into a subgoal L1), apply L in H matches H against L1 and, if successful, replaces it with L2.

In other words, apply L in H gives us a form of "forward reasoning" – from  $L1 \to L2$  and a hypothesis matching L1, it gives us a hypothesis matching L2. By contrast, apply L is "backward reasoning" – it says that if we know  $L1 \to L2$  and we are trying to prove L2, it suffices to prove L1.

Here is a variant of a proof from above, using forward reasoning throughout instead of backward reasoning.

```
Theorem silly3': \forall (n: \mathbf{nat}), (\mathsf{beq\_nat}\ n\ 5 = \mathsf{true} \to \mathsf{beq\_nat}\ (\mathsf{S}\ (\mathsf{S}\ n))\ 7 = \mathsf{true}) \to \mathsf{true} = \mathsf{beq\_nat}\ n\ 5 \to \mathsf{true} = \mathsf{beq\_nat}\ (\mathsf{S}\ (\mathsf{S}\ n))\ 7.

Proof.

intros n\ eq\ H.

symmetry in H. apply eq in H. symmetry in H. apply H. Qed.
```

Forward reasoning starts from what is *given* (premises, previously proven theorems) and iteratively draws conclusions from them until the goal is reached. Backward reasoning starts from the *goal*, and iteratively reasons about what would imply the goal, until premises or previously proven theorems are reached. If you've seen informal proofs before (for example, in a math or computer science class), they probably used forward reasoning. In general, Coq tends to favor backward reasoning, but in some situations the forward style can be easier to use or to think about.

Exercise: 3 stars (plus\_n\_n\_injective) Practice using "in" variants in this exercise.

```
Theorem plus_n_n_injective : \forall n \ m, n+n=m+m \rightarrow n=m.

Proof.

intros n. induction n as [\mid n'].

Admitted.
```

## 34.6 Varying the Induction Hypothesis

Sometimes it is important to control the exact form of the induction hypothesis when carrying out inductive proofs in Coq. In particular, we need to be careful about which of the assumptions we move (using intros) from the goal to the context before invoking the induction tactic. For example, suppose we want to show that the double function is injective – i.e., that it always maps different arguments to different results: Theorem double\_injective: for all n m, double n = 0 and n = 0 m. The way we start this proof is a little bit delicate: if we begin it with intros n. induction n. n = 0 all is well. But if we begin it with intros n m. induction n. we get stuck in the middle of the inductive case...

```
Theorem double_injective_FAILED: \forall \ n \ m, double n = double m \rightarrow n = m.

Proof.

intros n m. induction n as [\mid n'].

Case "n = O". simpl. intros eq. destruct m as [\mid m'].

SCase "m = O". reflexivity.

SCase "m = S m'". inversion eq.

Case "n = S n'". intros eq. destruct m as [\mid m'].

SCase "m = O". inversion eq.

SCase "m = O". inversion eq.

SCase "m = S m'". apply f_equal.

Abort.
```

The problem is that, at the point we invoke the induction hypothesis, we have already introduced m into the context – intuitively, we have told Coq, "Let's consider some particular n and m..." and we now have to prove that, if double  $n = double\ m$  for this particular n and m, then n = m.

The next tactic, induction n says to Coq: We are going to show the goal by induction on n. That is, we are going to prove that the proposition

```
• P n = "if double n = double m, then n = m" holds for all n by showing
```

What went wrong?

• P O

```
(i.e., "if double O = double m then <math>O = m")
```

•  $P n \rightarrow P (S n)$ 

(i.e., "if double  $n = double \ m \ then \ n = m$ " implies "if double  $(S \ n) = double \ m \ then \ S \ n = m$ ").

If we look closely at the second statement, it is saying something rather strange: it says that, for a particular m, if we know

• "if double n = double m then <math>n = m"

then we can prove

• "if double (S n) = double m then S n = m".

To see why this is strange, let's think of a particular m - say, 5. The statement is then saying that, if we know

• Q = "if double n = 10 then n = 5"

then we can prove

• R = ``if double (S n) = 10 then S n = 5''.

But knowing Q doesn't give us any help with proving  $\mathbb{R}$ ! (If we tried to prove  $\mathbb{R}$  from Q, we would say something like "Suppose double (S n) = 10..." but then we'd be stuck: knowing that double (S n) is 10 tells us nothing about whether double n is 10, so Q is useless at this point.)

To summarize: Trying to carry out this proof by induction on n when m is already in the context doesn't work because we are trying to prove a relation involving *every* n but just a  $single\ m$ .

The good proof of  $double\_injective$  leaves m in the goal statement at the point where the induction tactic is invoked on n:

```
Theorem double_injective: \forall n \ m, double n = double m \rightarrow n = m.

Proof.

intros n. induction n as [\mid n'].

Case \ "n = O". simpl. intros m eq. destruct m as [\mid m'].

SCase \ "m = O". reflexivity.

SCase \ "m = S \ m'". inversion eq.

Case \ "n = S \ n'".

intros m eq.
```

```
destruct m as [|m']. SCase "m = O". inversion eq. SCase "m = S m'". apply f_equal. apply IHn'. inversion eq. reflexivity. Qed.
```

What this teaches us is that we need to be careful about using induction to try to prove something too specific: If we're proving a property of n and m by induction on n, we may need to leave m generic.

The proof of this theorem has to be treated similarly:

```
Exercise: 2 stars (beq_nat_true) Theorem beq_nat_true : \forall n m, beq_nat n m = \text{true} \rightarrow n = m.

Proof.

Admitted.
```

Exercise: 2 stars, advanced (beq\_nat\_true\_informal) Give a careful informal proof of beq\_nat\_true, being as explicit as possible about quantifiers.

The strategy of doing fewer intros before an induction doesn't always work directly; sometimes a little *rearrangement* of quantified variables is needed. Suppose, for example, that we wanted to prove double\_injective by induction on m instead of n.

```
Theorem double_injective_take2_FAILED: \forall n \ m, double n = double m \rightarrow n = m.

Proof.

intros n \ m. induction m as [|m'].

Case \ "m = O". simpl. intros eq. destruct n as [|n'].

SCase \ "n = O". reflexivity.

SCase \ "n = S \ n'". inversion eq.

Case \ "m = S \ m'". intros eq. destruct n as [|n'].

SCase \ "n = O". inversion eq.

SCase \ "n = S \ n'". apply f_equal.

Abort.
```

The problem is that, to do induction on m, we must first introduce n. (If we simply say induction m without introducing anything first, Coq will automatically introduce n for us!)

What can we do about this? One possibility is to rewrite the statement of the lemma so that **m** is quantified before **n**. This will work, but it's not nice: We don't want to have to mangle the statements of lemmas to fit the needs of a particular strategy for proving them – we want to state them in the most clear and natural way.

What we can do instead is to first introduce all the quantified variables and then *regeneralize* one or more of them, taking them out of the context and putting them back at the beginning of the goal. The generalize dependent tactic does this.

```
Theorem double_injective_take2: \forall \ n \ m, double n = \text{double } m \rightarrow n = m.

Proof.

intros n \ m.

generalize dependent n.

induction m as [|m'].

Case \text{ "m} = O\text{". simpl. intros } n \ eq. \text{ destruct } n \text{ as } [|n'].

SCase \text{ "n} = O\text{". reflexivity.}

SCase \text{ "n} = S \text{ n'". inversion } eq.

Case \text{ "m} = S \text{ m'". intros } n \ eq. \text{ destruct } n \text{ as } [|n'].

SCase \text{ "n} = O\text{". inversion } eq.

SCase \text{ "n} = O\text{". inversion } eq.

SCase \text{ "n} = S \text{ n'". apply } f_{\text{equal.}}

SCase \text{ "n} = S \text{ n'". apply } f_{\text{equal.}}

SCase \text{ "n} = S \text{ n'". apply } f_{\text{equal.}}
```

Let's look at an informal proof of this theorem. Note that the proposition we prove by induction leaves n quantified, corresponding to the use of generalize dependent in our formal proof.

Theorem: For any nats n and m, if double n = double m, then n = m.

*Proof*: Let m be a **nat**. We prove by induction on m that, for any n, if double n = double m then n = m.

• First, suppose m = 0, and suppose n is a number such that double n = double m. We must show that n = 0.

Since m = 0, by the definition of double we have double n = 0. There are two cases to consider for n. If n = 0 we are done, since this is what we wanted to show. Otherwise, if n = S n' for some n', we derive a contradiction: by the definition of double we would have double n = S (S (double n')), but this contradicts the assumption that double n = 0.

Otherwise, suppose m = S m' and that n is again a number such that double n = double m. We must show that n = S m', with the induction hypothesis that for every number s, if double s = double m' then s = m'.

By the fact that m = S m' and the definition of double, we have double n = S (S (double m')). There are two cases to consider for n.

If n = 0, then by definition double n = 0, a contradiction. Thus, we may assume that n = S n' for some n', and again by the definition of double we have S (S (double n')) = S (S (double m')), which implies by inversion that double n' = S double m'.

Instantiating the induction hypothesis with n' thus allows us to conclude that n' =m', and it follows immediately that S n' = S m'. Since S n' = n and S m' = m, this is just what we wanted to show.  $\square$ Exercise: 3 stars (gen\_dep\_practice) Prove this by induction on l. Theorem index\_after\_last:  $\forall (n : nat) (X : Type) (l : list X)$ , length  $l = n \rightarrow$ index n l = None. Proof. Admitted. Exercise: 3 stars, advanced, optional (index\_after\_last\_informal) Write an informal proof corresponding to your Coq proof of index\_after\_last: Theorem: For all sets X, lists I: list X, and numbers n, if length I= n then index n I=None.  $Proof: \square$ Exercise: 3 stars, optional (gen\_dep\_practice\_more) Prove this by induction on I. Theorem length\_snoc''' :  $\forall (n : nat) (X : Type)$ (v:X) (l: list X),length  $l = n \rightarrow$ length (snoc l v) = S n. Proof. Admitted. Exercise: 3 stars, optional (app\_length\_cons) Prove this by induction on 11, without using app\_length. Theorem app\_length\_cons :  $\forall (X : Type) (l1 \ l2 : list \ X)$ (x:X) (n:nat), length  $(l1 ++ (x :: l2)) = n \rightarrow$ S (length (l1 ++ l2)) = n. Proof. Admitted. 

Exercise: 4 stars, optional (app\_length\_twice) Prove this by induction on I, without using app\_length.

```
Theorem app_length_twice : \forall (X:Type) (n:nat) (l:list X), length l = n \rightarrow
```

```
length (l ++ l) = n + n.
Proof. Admitted.
```

## 34.7 Using destruct on Compound Expressions

We have seen many examples where the destruct tactic is used to perform case analysis of the value of some variable. But sometimes we need to reason by cases on the result of some expression. We can also do this with destruct.

Here are some examples:

```
Definition sillyfun (n: nat): bool := if beq_nat n 3 then false else if beq_nat n 5 then false else false. Theorem sillyfun_false : <math>\forall (n: nat), sillyfun n = false. Proof.

intros n. unfold sillyfun.

destruct (beq_nat n 3).

Case "beq_nat n 3 = true". reflexivity.

Case "beq_nat n 3 = false". destruct (beq_nat n 5).

SCase "beq_nat n 5 = true". reflexivity.

SCase "beq_nat n 5 = false". reflexivity. Qed.
```

After unfolding sillyfun in the above proof, we find that we are stuck on if (beq\_nat n 3) then ... else .... Well, either n is equal to 3 or it isn't, so we use destruct (beq\_nat n 3) to let us reason about the two cases.

In general, the destruct tactic can be used to perform case analysis of the results of arbitrary computations. If e is an expression whose type is some inductively defined type T, then, for each constructor e of e0 (in the goal and in the context) are replaced by e0.

```
Exercise: 1 star (override_shadow) Theorem override_shadow : \forall (X:Type) x1 x2 k1 k2 (f : nat\rightarrowX), (override (override f k1 x2) k1 x1) k2 = (override f k1 x1) k2. Proof.

Admitted.
```

Exercise: 3 stars, optional (combine\_split) Complete the proof below Theorem combine\_split:  $\forall X Y (l : list (X \times Y)) l1 l2$ ,

```
split l = (l1, l2) \rightarrow combine l1 l2 = l.

Proof.

Admitted.
```

Sometimes, doing a destruct on a compound expression (a non-variable) will erase information we need to complete a proof. For example, suppose we define a function sillyfun1 like this:

```
Definition sillyfun1 (n : nat) : bool :=  if beq_nat n : 3 then true else if beq_nat n : 5 then true else false.
```

And suppose that we want to convince Coq of the rather obvious observation that sillyfun1 n yields true only when n is odd. By analogy with the proofs we did with sillyfun above, it is natural to start the proof like this:

```
Theorem sillyfun1_odd_FAILED : \forall (n : nat), sillyfun1 n = true \rightarrow oddb n = true.

Proof.

intros n eq. unfold sillyfun1 in eq. destruct (beq_nat n 3).

Abort.
```

We get stuck at this point because the context does not contain enough information to prove the goal! The problem is that the substitution performed by destruct is too brutal—it threw away every occurrence of  $deq_nat$  n 3, but we need to keep some memory of this expression and how it was destructed, because we need to be able to reason that since, in this branch of the case analysis,  $deq_nat$  n 3 =  $deq_nat$  n 3 =  $deq_nat$  n is odd.

What we would really like is to substitute away all existing occurrences of beq\_nat n 3, but at the same time add an equation to the context that records which case we are in. The eqn: qualifier allows us to introduce such an equation (with whatever name we choose).

```
Theorem sillyfun1_odd : \forall (n : nat), sillyfun1 n = true \rightarrow oddb n = true.

Proof.

intros n eq. unfold sillyfun1 in eq. destruct (beq_nat n 3) eqn:Heqe3.

Case "e3 = true". apply beq_nat_true in Heqe3. rewrite \rightarrow Heqe3. reflexivity.

Case "e3 = false".

destruct (beq_nat n 5) eqn:Heqe5.
```

```
SCase "e5 = true".
             apply beq_nat_true in Heqe5.
             rewrite \rightarrow Hege 5. reflexivity.
          SCase "e5 = false". inversion eq. Qed.
Exercise: 2 stars (destruct_eqn_practice) Theorem bool_fn_applied_thrice:
  \forall (f : \mathsf{bool} \to \mathsf{bool}) (b : \mathsf{bool}),
  f(f(f(b)) = f(b)
Proof.
    Admitted.
   Exercise: 2 stars (override_same) Theorem override_same : \forall (X:Type) x1 k1 k2 (f :
nat \rightarrow X),
  f k1 = x1 \rightarrow
  (override f \ k1 \ x1) k2 = f \ k2.
Proof.
    Admitted.
```

#### 34.8 Review

We've now seen a bunch of Coq's fundamental tactics. We'll introduce a few more as we go along through the coming lectures, and later in the course we'll introduce some more powerful *automation* tactics that make Coq do more of the low-level work in many cases. But basically we've got what we need to get work done.

Here are the ones we've seen:

- intros: move hypotheses/variables from goal to context
- reflexivity: finish the proof (when the goal looks like e = e)
- apply: prove goal using a hypothesis, lemma, or constructor
- apply... in H: apply a hypothesis, lemma, or constructor to a hypothesis in the context (forward reasoning)
- apply... with...: explicitly specify values for variables that cannot be determined by pattern matching
- simpl: simplify computations in the goal
- simpl in H: ... or a hypothesis

- rewrite: use an equality hypothesis (or lemma) to rewrite the goal
- rewrite ... in H: ... or a hypothesis
- symmetry: changes a goal of the form t=u into u=t
- symmetry in H: changes a hypothesis of the form t=u into u=t
- unfold: replace a defined constant by its right-hand side in the goal
- unfold... in H: ... or a hypothesis
- destruct... as...: case analysis on values of inductively defined types
- destruct... eqn:...: specify the name of an equation to be added to the context, recording the result of the case analysis
- induction... as...: induction on values of inductively defined types
- inversion: reason by injectivity and distinctness of constructors
- ullet assert (e) as H: introduce a "local lemma" e and call it H
- generalize dependent x: move the variable x (and anything else that depends on it) from the context back to an explicit hypothesis in the goal formula

#### 34.9 Additional Exercises

```
Exercise: 3 stars (beq_nat_sym) Theorem beq_nat_sym : \forall (n m : nat),
  beq_nat n m = beq_nat m n.
Proof.
   Admitted.
   Exercise: 3 stars, advanced, optional (beq_nat_sym_informal) Give an informal
proof of this lemma that corresponds to your formal proof above:
   Theorem: For any nats n m, beq_nat n m = beq_nat m n.
   Proof: \square
Exercise: 3 stars, optional (beq_nat_trans) Theorem beq_nat_trans: \forall n \ m \ p,
  beg_nat n m = true \rightarrow
  beg_nat m p = true \rightarrow
  beq_nat n p = true.
Proof.
   Admitted.
```

Exercise: 3 stars, advanced (split\_combine) We have just proven that for all lists of pairs, combine is the inverse of split. How would you formalize the statement that split is the inverse of combine?

Complete the definition of split\_combine\_statement below with a property that states that split is the inverse of combine. Then, prove that the property holds. (Be sure to leave your induction hypothesis general by not doing intros on more things than necessary. Hint: what property do you need of l1 and l2 for split combine l1 l2 = (l1, l2) to be true?)

```
Definition split_combine_statement : Prop :=
admit.
Theorem split_combine : split_combine_statement.
Proof.
```

Admitted.  $\Box$ 

```
Exercise: 3 stars (override_permute) Theorem override_permute : \forall (X:Type) x1 x2 k1 k2 k3 (f : nat \rightarrow X), beq_nat k2 k1 = false \rightarrow (override (override f k2 x2) k1 x1) k3 = (override (override f k1 x1) k2 x2) k3. Proof.

Admitted.
```

Exercise: 3 stars, advanced (filter\_exercise) This one is a bit challenging. Pay attention to the form of your IH.

```
Theorem filter_exercise : \forall (X: \mathsf{Type}) \ (test: X \to \mathbf{bool}) (x: X) \ (l \ lf: \mathbf{list} \ X), filter test \ l = x :: lf \to test \ x = \mathsf{true}. Proof.

Admitted.
```

Exercise: 4 stars, advanced (forall\_exists\_challenge) Define two recursive Fixpoints, forallb and existsb. The first checks whether every element in a list satisfies a given predicate: forallb oddb 1;3;5;7;9 = true

```
forallb negb false; false = true
forallb evenb 0;2;4;5 = false
```

for all b (beq\_nat 5)  $\square$  = true The second checks whether there exists an element in the list that satisfies a given predicate: exists (beq\_nat 5) 0;2;3;6 = false

```
existsb (andb true) true;true;false = true existsb oddb 1;0;0;0;0;3 = true
```

exists $\Box$ = false Next, define a nonrecursive version of exists $b$ - call it exists $b$ ' -
using forallb and negb.
Prove that existsb' and existsb have the same behavior.

## Chapter 35

# Library Poly

## 35.1 Poly: Polymorphism and Higher-Order Functions

In this chapter we continue our development of basic concepts of functional programming. The critical new ideas are *polymorphism* (abstracting functions over the types of the data they manipulate) and *higher-order functions* (treating functions as data).

Require Export Lists.

## 35.2 Polymorphism

### 35.2.1 Polymorphic Lists

For the last couple of chapters, we've been working just with lists of numbers. Obviously, interesting programs also need to be able to manipulate lists with elements from other types – lists of strings, lists of booleans, lists of lists, etc. We *could* just define a new inductive datatype for each of these, for example...

```
Inductive boollist : Type :=
  | bool_nil : boollist
  | bool_cons : bool → boollist → boollist.
```

... but this would quickly become tedious, partly because we have to make up different constructor names for each datatype, but mostly because we would also need to define new versions of all our list manipulating functions (length, rev, etc.) for each new datatype definition.

To avoid all this repetition, Coq supports *polymorphic* inductive type definitions. For example, here is a *polymorphic list* datatype.

```
Inductive list (X:Type): Type :=  | nil : list X | cons : X \to  list X \to  list X.
```

This is exactly like the definition of **natlist** from the previous chapter, except that the **nat** argument to the **cons** constructor has been replaced by an arbitrary type X, a binding for X has been added to the header, and the occurrences of **natlist** in the types of the constructors have been replaced by **list** X. (We can re-use the constructor names nil and **cons** because the earlier definition of **natlist** was inside of a Module definition that is now out of scope.)

What sort of thing is **list** itself? One good way to think about it is that **list** is a function from Types to Inductive definitions; or, to put it another way, **list** is a function from Types to Types. For any particular type X, the type **list** X is an Inductively defined set of lists whose elements are things of type X.

With this definition, when we use the constructors nil and cons to build lists, we need to tell Coq the type of the elements in the lists we are building – that is, nil and cons are now polymorphic constructors. Observe the types of these constructors:

Check nil.

Check cons.

The " $\forall$  X" in these types can be read as an additional argument to the constructors that determines the expected types of the arguments that follow. When nil and cons are used, these arguments are supplied in the same way as the others. For example, the list containing 2 and 1 is written like this:

```
Check (cons nat 2 (cons nat 1 (nil nat))).
```

(We've gone back to writing nil and cons explicitly here because we haven't yet defined the [] and :: notations for the new version of lists. We'll do that in a bit.)

We can now go back and make polymorphic (or "generic") versions of all the list-processing functions that we wrote before. Here is length, for example:

```
Fixpoint length (X: \mathsf{Type}) (l: \mathsf{list}\ X) : \mathsf{nat} := \mathsf{match}\ l \ \mathsf{with} |\ \mathsf{nil} \Rightarrow 0 |\ \mathsf{cons}\ h\ t \Rightarrow \mathsf{S}\ (\mathsf{length}\ X\ t) \ \mathsf{end}.
```

Note that the uses of nil and cons in match patterns do not require any type annotations: Coq already knows that the list I contains elements of type X, so there's no reason to include X in the pattern. (More precisely, the type X is a parameter of the whole definition of list, not of the individual constructors. We'll come back to this point later.)

As with nil and cons, we can use length by applying it first to a type and then to its list argument:

To use our length with other kinds of lists, we simply instantiate it with an appropriate type parameter:

```
Example test_length2:
```

```
length bool (cons bool true (nil bool)) = 1.
Proof. reflexivity. Qed.
    Let's close this subsection by re-implementing a few other standard list functions on our
new polymorphic lists:
Fixpoint app (X : Type) (l1 \ l2 : list \ X)
                     : (list X) :=
  {\tt match}\ l1\ {\tt with}
   \mid \mathsf{nil} \Rightarrow l2
  | cons h t \Rightarrow cons X h (app X t l2) |
  end.
Fixpoint snoc (X:Type) (l:list X) (v:X) : (list X) :=
  \mathtt{match}\ l with
   \mathsf{nil} \Rightarrow \mathsf{cons}\ X\ v\ (\mathsf{nil}\ X)
  |\cos h| t \Rightarrow \cos X h (\operatorname{snoc} X t v)
  end.
Fixpoint rev (X:Type) (l:list X):list X:=
  {\tt match}\ l\ {\tt with}
   | \mathsf{nil} \Rightarrow \mathsf{nil} \ X
   | cons h t \Rightarrow snoc X (rev X t) h
  end.
Example test_rev1 :
     rev nat (cons nat 1 (cons nat 2 (nil nat)))
  = (cons nat 2 (cons nat 1 (nil nat))).
Proof. reflexivity. Qed.
Example test_rev2:
  rev bool (nil bool) = nil bool.
Proof. reflexivity. Qed.
Module MUMBLEBAZ.
Exercise: 2 stars (mumble_grumble) Consider the following two inductively defined
types.
Inductive mumble: Type :=
    a: mumble
    b : mumble \rightarrow nat \rightarrow mumble
  c: mumble.
Inductive grumble (X:Type): Type :=
   | d : mumble \rightarrow grumble X
  \mid e : X \rightarrow grumble X.
```

Which of the following are well-typed elements of **grumble** X for some type X?

```
d (b a 5)
d mumble (b a 5)
d bool (b a 5)
e bool true
e mumble (b c 0)
e bool (b c 0)
c
```

Exercise: 2 stars (baz\_num\_elts) Consider the following inductive definition:

```
\begin{array}{l} \text{Inductive baz} : \texttt{Type} := \\ \mid \texttt{x} : \texttt{baz} \rightarrow \texttt{baz} \\ \mid \texttt{y} : \texttt{baz} \rightarrow \texttt{bool} \rightarrow \texttt{baz}. \end{array}
```

How many elements does the type **baz** have?  $\square$ 

End MUMBLEBAZ.

#### Type Annotation Inference

Let's write the definition of app again, but this time we won't specify the types of any of the arguments. Will Coq still accept it?

```
Fixpoint app' X l1 l2 : list X := match l1 with | nil \Rightarrow l2 | cons h t \Rightarrow cons X h (app' X t l2) end
```

Indeed it will. Let's see what type Coq has assigned to app':

Check app'. Check app.

It has exactly the same type type as app. Coq was able to use a process called *type inference* to deduce what the types of X, l1, and l2 must be, based on how they are used. For example, since X is used as an argument to cons, it must be a Type, since cons expects a Type as its first argument; matching l1 with nil and cons means it must be a **list**; and so on.

This powerful facility means we don't always have to write explicit type annotations everywhere, although explicit type annotations are still quite useful as documentation and sanity checks. You should try to find a balance in your own code between too many type annotations (so many that they clutter and distract) and too few (which forces readers to perform type inference in their heads in order to understand your code).

#### Type Argument Synthesis

Whenever we use a polymorphic function, we need to pass it one or more types in addition to its other arguments. For example, the recursive call in the body of the length function above must pass along the type X. But just like providing explicit type annotations everywhere, this is heavy and verbose. Since the second argument to length is a list of Xs, it seems entirely obvious that the first argument can only be X – why should we have to write it explicitly?

Fortunately, Coq permits us to avoid this kind of redundancy. In place of any type argument we can write the "implicit argument" \_, which can be read as "Please figure out for yourself what type belongs here." More precisely, when Coq encounters a \_, it will attempt to *unify* all locally available information – the type of the function being applied, the types of the other arguments, and the type expected by the context in which the application appears – to determine what concrete type should replace the \_.

This may sound similar to type annotation inference – and, indeed, the two procedures rely on the same underlying mechanisms. Instead of simply omitting the types of some arguments to a function, like app' X l1 l2 : list X := we can also replace the types with  $\_$ , like app'  $(X : \_)$  (l1 l2 :  $\_$ ) : list X := which tells Coq to attempt to infer the missing information, just as with argument synthesis.

Using implicit arguments, the length function can be written like this:

```
Fixpoint length' (X: \mathsf{Type}) (l: \mathsf{list}\ X): \mathsf{nat}:= \mathsf{match}\ l with |\mathsf{nil}| \Rightarrow 0 |\mathsf{cons}\ h\ t \Rightarrow \mathsf{S}\ (\mathsf{length}'\ _t) end.
```

In this instance, we don't save much by writing \_ instead of X. But in many cases the difference can be significant. For example, suppose we want to write down a list containing the numbers 1, 2, and 3. Instead of writing this...

```
Definition list123 :=
  cons nat 1 (cons nat 2 (cons nat 3 (nil nat))).
  ...we can use argument synthesis to write this:
Definition list123' := cons _ 1 (cons _ 2 (cons _ 3 (nil _))).
```

#### Implicit Arguments

If fact, we can go further. To avoid having to sprinkle \_'s throughout our programs, we can tell Coq always to infer the type argument(s) of a given function. The Arguments directive specifies the name of the function or constructor, and then lists its argument names, with curly brackets around any arguments to be treated as implicit.

```
Arguments nil \{X\}.
Arguments cons \{X\} _ _. Arguments length \{X\} l.
Arguments app \{X\} l1 l2.
Arguments rev \{X\} l.
```

```
Arguments snoc \{X\} l v.

Definition list123'' := cons 1 (cons 2 (cons 3 nil)).

Check (length list123'').
```

Alternatively, we can declare an argument to be implicit while defining the function itself, by surrounding the argument in curly braces. For example:

```
Fixpoint length" \{X: \mathtt{Type}\}\ (l: \mathtt{list}\ X): \mathtt{nat}:= \mathtt{match}\ l \ \mathtt{with} | \mathtt{nil}\Rightarrow 0 | \mathtt{cons}\ h\ t\Rightarrow \mathtt{S}\ (\mathtt{length}''\ t) end.
```

(Note that we didn't even have to provide a type argument to the recursive call to length"; indeed, it is invalid to provide one.) We will use this style whenever possible, although we will continue to use use explicit *Argument* declarations for Inductive constructors.

One small problem with declaring arguments Implicit is that, occasionally, Coq does not have enough local information to determine a type argument; in such cases, we need to tell Coq that we want to give the argument explicitly this time, even though we've globally declared it to be Implicit. For example, suppose we write this:

If we uncomment this definition, Coq will give us an error, because it doesn't know what type argument to supply to nil. We can help it by providing an explicit type declaration (so that Coq has more information available when it gets to the "application" of nil):

```
Definition mynil: list nat := nil.
```

Alternatively, we can force the implicit arguments to be explicit by prefixing the function name with @.

Check @nil.

```
Definition mynil' := @nil nat.
```

Using argument synthesis and implicit arguments, we can define convenient notation for lists, as before. Since we have made the constructor type arguments implicit, Coq will know to automatically infer these when we use the notations.

Definition list123''' := [1; 2; 3].

#### Exercises: Polymorphic Lists

Exercise: 2 stars, optional (poly\_exercises) Here are a few simple exercises, just like ones in the Lists chapter, for practice with polymorphism. Fill in the definitions and complete the proofs below.

```
Fixpoint repeat \{X : \mathsf{Type}\}\ (n : X)\ (count : \mathsf{nat}) : \mathsf{list}\ X :=
  admit.
Example test_repeat1:
  repeat true 2 = cons true (cons true nil).
    Admitted.
Theorem nil_app : \forall X:Type, \forall l:list X,
  app [] l = l.
Proof.
    Admitted.
Theorem rev_snoc : \forall X : Type,
                            \forall v: X
                            \forall s :  list X,
  rev (snoc s v) = v :: (rev s).
Proof.
    Admitted.
Theorem rev_involutive : \forall X : Type, \forall l : list X,
  rev (rev l) = l.
Proof.
    Admitted.
Theorem snoc_with_append : \forall X : Type,
                                 \forall l1 l2 : list X,
                                 \forall v: X
  snoc (l1 ++ l2) v = l1 ++ (snoc l2 v).
Proof.
    Admitted.
```

### 35.2.2 Polymorphic Pairs

Following the same pattern, the type definition we gave in the last chapter for pairs of numbers can be generalized to *polymorphic pairs* (or *products*):

```
Inductive prod (X \ Y : \mathsf{Type}) : \mathsf{Type} := \mathsf{pair} : X \to Y \to \mathsf{prod} \ X \ Y.
Arguments \ \mathsf{pair} \ \{X\} \ \{Y\} \ \_ \ \_.
```

As with lists, we make the type arguments implicit and define the familiar concrete notation.

```
Notation "(x, y)" := (pair x y).
```

We can also use the Notation mechanism to define the standard notation for pair types:

```
Notation "X * Y" := (\mathbf{prod} \ X \ Y) : type\_scope.
```

(The annotation: type\_scope tells Coq that this abbreviation should be used when parsing types. This avoids a clash with the multiplication symbol.)

A note of caution: it is easy at first to get (x,y) and  $X \times Y$  confused. Remember that (x,y) is a *value* built from two other values;  $X \times Y$  is a *type* built from two other types. If x has type X and y has type Y, then (x,y) has type  $X \times Y$ .

The first and second projection functions now look pretty much as they would in any functional programming language.

```
Definition fst \{X \mid Y : \mathtt{Type}\}\ (p : X \times Y) : X := \mathtt{match}\ p \ \mathtt{with}\ (x,y) \Rightarrow x \ \mathtt{end}. Definition snd \{X \mid Y : \mathtt{Type}\}\ (p : X \times Y) : Y := \mathtt{match}\ p \ \mathtt{with}\ (x,y) \Rightarrow y \ \mathtt{end}.
```

The following function takes two lists and combines them into a list of pairs. In many functional programming languages, it is called *zip*. We call it **combine** for consistency with Coq's standard library. Note that the pair notation can be used both in expressions and in patterns...

```
Fixpoint combine \{X \mid Y : \mathsf{Type}\}\ (lx : \mathsf{list} \mid X) \ (ly : \mathsf{list} \mid Y) : \mathsf{list} \mid (X \times Y) := match (lx, ly) with | \ ([], \_) \Rightarrow [] \ | \ (\_, []) \Rightarrow [] \ | \ (x : : tx, \ y : : ty) \Rightarrow (x, y) :: \text{ (combine } tx \mid ty) end.
```

Exercise: 1 star, optional (combine\_checks) Try answering the following questions on paper and checking your answers in coq:

- What is the type of combine (i.e., what does Check @combine print?)
- What does Eval compute in (combine 1;2 false;false;true;true). print?

Exercise: 2 stars (split) The function split is the right inverse of combine: it takes a list of pairs and returns a pair of lists. In many functional programing languages, this function is called *unzip*.

Uncomment the material below and fill in the definition of split. Make sure it passes the given unit tests.

```
Fixpoint split
```

```
\{X \mid Y : \mathsf{Type}\}\ (l : \mathsf{list}\ (X \times Y))
```

```
: (\textbf{list } X) \times (\textbf{list } Y) := \\ \textit{admit}. \\ \texttt{Example test\_split:} \\ \textit{split } [(1, \mathsf{false}); (2, \mathsf{false})] = ([1; 2], [\mathsf{false}; \mathsf{false}]). \\ \texttt{Proof.} \\ \textit{Admitted.} \\ \square
```

#### 35.2.3 Polymorphic Options

One last polymorphic type for now: *polymorphic options*. The type declaration generalizes the one for **natoption** in the previous chapter:

```
Inductive option (X:Type): Type := |Some: X \to option X| |None: option X.  |Arguments Some <math>\{X\} _...  |Arguments None \{X\}.
```

We can now rewrite the index function so that it works with any type of lists.

```
Fixpoint index \{X: \mathsf{Type}\}\ (n: \mathsf{nat}) (l: \mathsf{list}\ X): \mathsf{option}\ X:= \mathsf{match}\ l \ \mathsf{with} |\ [] \Rightarrow \mathsf{None} |\ a::\ l' \Rightarrow \mathsf{if}\ \mathsf{beq\_nat}\ n \ \mathsf{O}\ \mathsf{then}\ \mathsf{Some}\ a \ \mathsf{else}\ \mathsf{index}\ (\mathsf{pred}\ n)\ l' \ \mathsf{end}. Example test_index1: index 0 [4;5;6;7] = Some 4. Proof. reflexivity. Qed. Example test_index2: index 1 [[1];[2]] = Some [2]. Proof. reflexivity. Qed. Example test_index3: index 2 [true] = \mathsf{None}.
```

Exercise: 1 star, optional (hd\_opt\_poly) Complete the definition of a polymorphic version of the hd\_opt function from the last chapter. Be sure that it passes the unit tests below.

Once again, to force the implicit arguments to be explicit, we can use @ before the name of the function.

```
Check @hd_opt.
```

Proof. reflexivity. Qed.

```
Example test_hd_opt1 : hd_opt [1;2] = Some 1.
```

```
 \begin{array}{l} Admitted. \\ {\tt Example test\_hd\_opt2: hd\_opt \ [[1];[2]] = Some \ [1].} \\ Admitted. \\ \square \end{array}
```

## 35.3 Functions as Data

#### 35.3.1 Higher-Order Functions

Like many other modern programming languages – including all functional languages (ML, Haskell, Scheme, etc.) – Coq treats functions as first-class citizens, allowing functions to be passed as arguments to other functions, returned as results, stored in data structures, etc.

Functions that manipulate other functions are often called *higher-order* functions. Here's a simple one:

```
Definition doit3times \{X: \texttt{Type}\}\ (f: X \to X)\ (n: X): X := f\ (f\ (f\ n)).
```

The argument f here is itself a function (from X to X); the body of doit3times applies f three times to some value n.

Check @doit3times.

```
Example test_doit3times: doit3times minustwo 9 = 3. Proof. reflexivity. Qed.

Example test_doit3times': doit3times negb true = false. Proof. reflexivity. Qed.
```

### 35.3.2 Partial Application

In fact, the multiple-argument functions we have already seen are also examples of passing functions as data. To see why, recall the type of plus.

Check plus.

Each  $\rightarrow$  in this expression is actually a binary operator on types. (This is the same as saying that Coq primitively supports only one-argument functions – do you see why?) This operator is right-associative, so the type of plus is really a shorthand for  $nat \rightarrow (nat \rightarrow nat)$  – i.e., it can be read as saying that "plus is a one-argument function that takes a nat and returns a one-argument function that takes another nat and returns a nat." In the examples above, we have always applied plus to both of its arguments at once, but if we like we can supply just the first. This is called partial application.

```
Definition plus3 := plus 3.
Check plus3.
Example test_plus3 : plus3 4 = 7.
Proof. reflexivity. Qed.
```

```
Example test_plus3': doit3times plus3 0 = 9.

Proof. reflexivity. Qed.

Example test_plus3'': doit3times (plus 3) 0 = 9.

Proof. reflexivity. Qed.
```

#### 35.3.3 Digression: Currying

**Exercise: 2 stars, advanced (currying)** In Coq, a function  $f : A \to B \to C$  really has the type  $A \to (B \to C)$ . That is, if you give f a value of type A, it will give you function f':  $B \to C$ . If you then give f' a value of type B, it will return a value of type C. This allows for partial application, as in plus A. Processing a list of arguments with functions that return functions is called *currying*, in honor of the logician Haskell Curry.

Conversely, we can reinterpret the type  $A \to B \to C$  as  $(A \times B) \to C$ . This is called *uncurrying*. With an uncurried binary function, both arguments must be given at once as a pair; there is no partial application.

We can define currying as follows:

```
 \begin{array}{l} {\tt Definition\ prod\_curry}\ \{X\ Y\ Z: {\tt Type}\}\\ (f: X\times Y\to Z)\ (x: X)\ (y: Y): Z:=f\ (x,\ y). \end{array}
```

As an exercise, define its inverse, prod\_uncurry. Then prove the theorems below to show that the two are inverses.

```
Definition prod_uncurry \{X \ Y \ Z : \mathtt{Type}\}\ (f: X \to Y \to Z) \ (p: X \times Y) : Z := \mathit{admit}.
```

(Thought exercise: before running these commands, can you calculate the types of prod\_curry and prod\_uncurry?)

```
Check @prod_curry.
Check @prod_uncurry.
```

```
Theorem uncurry_curry : \forall (X Y Z : Type) (f : X \rightarrow Y \rightarrow Z) x y, prod_curry (prod_uncurry f) x y = f x y.
```

Admitted.

```
\label{eq:theorem_curry_uncurry} \begin{array}{c} \text{Theorem curry\_uncurry}: \ \forall \ (X \ Y \ Z: \texttt{Type}) \\ \qquad \qquad (f: (X \times Y) \to Z) \ (p: X \times Y), \\ \text{prod\_uncurry (prod\_curry } f) \ p = f \ p. \\ \text{Proof.} \\ Admitted. \end{array}
```

#### 35.3.4 Filter

Here is a useful higher-order function, which takes a list of Xs and a *predicate* on X (a function from X to **bool**) and "filters" the list, returning a new list containing just those elements for which the predicate returns **true**.

```
Fixpoint filter \{X: \mathsf{Type}\}\ (test:\ X \to \mathsf{bool})\ (l: \mathsf{list}\ X) := \mathsf{match}\ l \ \mathsf{with} \ |\ [] \Rightarrow [] \ |\ h ::\ t \Rightarrow \mathsf{if}\ test\ h \ \mathsf{then}\ h ::\ (\mathsf{filter}\ test\ t) \ \mathsf{else}\ \mathsf{filter}\ test\ t \ \mathsf{end}.
```

For example, if we apply filter to the predicate evenb and a list of numbers I, it returns a list containing just the even members of I.

```
Example test_filter1: filter evenb [1;2;3;4] = [2;4]. Proof. reflexivity. Qed.

Definition length_is_1 \{X: \text{Type}\}\ (l: \text{list } X): \text{bool} := \text{beq\_nat (length } l) 1.

Example test_filter2:
    filter length_is_1
        [ [1; 2]; [3]; [4]; [5;6;7]; []; [8] ]
        = [ [3]; [4]; [8] ].

Proof. reflexivity. Qed.
```

We can use filter to give a concise version of the countoddmembers function from the Lists chapter.

```
Definition countoddmembers' (l:list nat) : nat :=
  length (filter oddb l).

Example test_countoddmembers'1: countoddmembers' [1;0;3;1;4;5] = 4.
Proof. reflexivity. Qed.
Example test_countoddmembers'2: countoddmembers' [0;2;4] = 0.
Proof. reflexivity. Qed.
Example test_countoddmembers'3: countoddmembers' nil = 0.
Proof. reflexivity. Qed.
```

### 35.3.5 Anonymous Functions

It is a little annoying to be forced to define the function <code>length\_is\_1</code> and give it a name just to be able to pass it as an argument to filter, since we will probably never use it again. Moreover, this is not an isolated example. When using higher-order functions, we often want to pass as arguments "one-off" functions that we will never use again; having to give each of these functions a name would be tedious.

Fortunately, there is a better way. It is also possible to construct a function "on the fly" without declaring it at the top level or giving it a name; this is analogous to the notation we've been using for writing down constant lists, natural numbers, and so on.

```
Example test_anon_fun': doit3times (fun n \Rightarrow n \times n) 2 = 256. Proof. reflexivity. Qed.
```

Here is the motivating example from before, rewritten to use an anonymous function.

Example test\_filter2':

```
filter (fun l \Rightarrow beq_nat (length l) 1)

[ [1; 2]; [3]; [4]; [5;6;7]; []; [8] ]

= [ [3]; [4]; [8] ].

Proof. reflexivity. Qed.
```

Exercise: 2 stars (filter\_even\_gt7) Use filter (instead of Fixpoint) to write a Coq function filter\_even\_gt7 that takes a list of natural numbers as input and returns a list of just those that are even and greater than 7.

```
Definition filter_even_gt7 (l : list nat) : list nat := admit.

Example test_filter_even_gt7_1 : filter_even_gt7 [1;2;6;9;10;3;12;8] = [10;12;8]. Admitted.

Example test_filter_even_gt7_2 : filter_even_gt7 [5;2;6;19;129] = []. Admitted.
```

**Exercise: 3 stars (partition)** Use filter to write a Coq function partition: partition: forall X: Type,  $(X \to bool) \to list X \to list X$  ist X Given a set X, a test function of type  $X \to bool$  and a list X, partition should return a pair of lists. The first member of the pair is the sublist of the original list containing the elements that satisfy the test, and the second is the sublist containing those that fail the test. The order of elements in the two sublists should be the same as their order in the original list.

```
Definition partition \{X: \mathsf{Type}\}\ (test: X \to \mathsf{bool})\ (l: \mathsf{list}\ X) : \mathsf{list}\ X \times \mathsf{list}\ X := admit. 
 Example test_partition1: partition oddb [1;2;3;4;5] = ([1;3;5], [2;4]). Admitted. 
 Example test_partition2: partition (fun x \Rightarrow \mathsf{false}) [5;9;0] = ([], [5;9;0]). Admitted.
```

#### 35.3.6 Map

Another handy higher-order function is called map.

```
\begin{split} \texttt{Fixpoint map} \; \{X \; Y : \texttt{Type}\} \; (f : X \to Y) \; (l : \textbf{list} \; X) \\ & : \; (\textbf{list} \; Y) := \\ & \texttt{match} \; l \; \texttt{with} \\ & | \; [] \; \Rightarrow \; [] \\ & | \; h \; : : \; t \; \Rightarrow \; (f \; h) \; : : \; (\texttt{map} \; f \; t) \\ & \texttt{end.} \end{split}
```

It takes a function f and a list I = [n1, n2, n3, ...] and returns the list  $[f \ n1, f \ n2, f \ n3,...]$ , where f has been applied to each element of I in turn. For example:

```
Example test_map1: map (plus 3) [2;0;2] = [5;3;5]. Proof. reflexivity. Qed.
```

The element types of the input and output lists need not be the same (map takes two type arguments, X and Y). This version of map can thus be applied to a list of numbers and a function from numbers to booleans to yield a list of booleans:

```
Example test_map2: map oddb [2;1;2;5] = [false;true;false;true]. Proof. reflexivity. Qed.
```

It can even be applied to a list of numbers and a function from numbers to *lists* of booleans to yield a list of lists of booleans:

```
Example test_map3:
```

```
map (fun n \Rightarrow [evenb n; oddb n]) [2;1;2;5] = [[true; false]; [false; true]; [true; false]; [false; true]]. Proof. reflexivity. Qed.
```

Exercise: 3 stars (map\_rev) Show that map and rev commute. You may need to define an auxiliary lemma.

```
Theorem map_rev : \forall (X Y : Type) (f : X \rightarrow Y) (l : list X), map f (rev l) = rev (map f l). Proof.

Admitted.
```

Exercise: 2 stars (flat\_map) The function map maps a list X to a list Y using a function of type  $X \to Y$ . We can define a similar function, flat\_map, which maps a list X to a list Y using a function f of type  $X \to list Y$ . Your definition should work by 'flattening' the results of f, like so: flat\_map (fun n => n;n+1;n+2) 1;5;10 = 1; 2; 3; 5; 6; 7; 10; 11; 12.

```
Fixpoint flat_map \{X \mid Y : \texttt{Type}\}\ (f : X \to \mathsf{list}\ Y)\ (l : \mathsf{list}\ X) := admit.
```

```
Example test_flat_map1: flat_map (fun n \Rightarrow [n; n; n]) [1;5;4] = [1; 1; 1; 5; 5; 5; 4; 4; 4]. Admitted.
```

Lists are not the only inductive type that we can write a map function for. Here is the definition of map for the **option** type:

```
 \begin{array}{c} \mathsf{Definition\ option\_map}\ \{X\ Y: \mathsf{Type}\}\ (f:X\to Y)\ (xo: \mathbf{option}\ X)\\ : \mathbf{option}\ Y:=\\ \\ \mathsf{match}\ xo\ \mathsf{with}\\ \mid \mathsf{None}\Rightarrow \mathsf{None}\\ \mid \mathsf{Some}\ x\Rightarrow \mathsf{Some}\ (f\ x)\\ \\ \mathsf{end}. \end{array}
```

Exercise: 2 stars, optional (implicit\_args) The definitions and uses of filter and map use implicit arguments in many places. Replace the curly braces around the implicit arguments with parentheses, and then fill in explicit type parameters where necessary and use Coq to check that you've done so correctly. (This exercise is not to be turned in; it is probably easiest to do it on a *copy* of this file that you can throw away afterwards.)  $\square$ 

#### 35.3.7 Fold

An even more powerful higher-order function is called **fold**. This function is the inspiration for the "reduce" operation that lies at the heart of Google's map/reduce distributed programming framework.

```
Fixpoint fold \{X \mid Y : \mathsf{Type}\}\ (f \colon X \to Y \to Y)\ (l : \mathsf{list}\ X)\ (b \colon Y) \colon Y := \mathsf{match}\ l \ \mathsf{with} | \ \mathsf{nil} \Rightarrow b | \ h \colon \colon t \Rightarrow f \ h \ (\mathsf{fold}\ f \ t \ b) end.
```

Intuitively, the behavior of the fold operation is to insert a given binary operator f between every pair of elements in a given list. For example, fold plus [1;2;3;4] intuitively means 1+2+3+4. To make this precise, we also need a "starting element" that serves as the initial second input to f. So, for example, fold plus 1;2;3;4 0 yields 1 + (2 + (3 + (4 + 0))). Here are some more examples:

```
Check (fold andb).

Example fold_example1: fold mult [1;2;3;4] 1 = 24.

Proof. reflexivity. Qed.

Example fold_example2: fold andb [true;true;false;true] true = false.

Proof. reflexivity. Qed.
```

```
Example fold_example3 : fold app [[1];[];[2;3];[4]] [] = [1;2;3;4]. Proof. reflexivity. Qed.
```

Exercise: 1 star, advanced (fold\_types\_different) Observe that the type of fold is parameterized by two type variables, X and Y, and the parameter f is a binary operator that takes an X and a Y and returns a Y. Can you think of a situation where it would be useful for X and Y to be different?

#### 35.3.8 Functions For Constructing Functions

Most of the higher-order functions we have talked about so far take functions as arguments. Now let's look at some examples involving returning functions as the results of other functions.

To begin, here is a function that takes a value x (drawn from some type X) and returns a function from **nat** to X that yields x whenever it is called, ignoring its **nat** argument.

```
Definition constfun \{X \colon \mathsf{Type}\}\ (x \colon X) : \mathsf{nat} \to X := \mathsf{fun}\ (k \colon \mathsf{nat}) \Rightarrow x.
Definition ftrue := constfun true.

Example constfun_example1 : ftrue 0 = \mathsf{true}.

Proof. reflexivity. Qed.

Example constfun_example2 : (constfun 5) 99 = 5.

Proof. reflexivity. Qed.
```

Similarly, but a bit more interestingly, here is a function that takes a function f from numbers to some type X, a number k, and a value x, and constructs a function that behaves exactly like f except that, when called with the argument k, it returns x.

```
Definition override \{X : \mathsf{Type}\}\ (f : \mathsf{nat} \to X)\ (k : \mathsf{nat})\ (x : X) : \mathsf{nat} \to X := \mathsf{fun}\ (k' : \mathsf{nat}) \Rightarrow \mathsf{if}\ \mathsf{beq\_nat}\ k\ k'\ \mathsf{then}\ x\ \mathsf{else}\ f\ k'.
```

For example, we can apply override twice to obtain a function from numbers to booleans that returns false on 1 and 3 and returns true on all other arguments.

```
Definition fmostlytrue := override (override ftrue 1 false) 3 false.
Example override_example1 : fmostlytrue 0 = \text{true}.
```

Proof. reflexivity. Qed.

Example override\_example2 : fmostlytrue 1 = false.

Proof. reflexivity. Qed.

Example override\_example3 : fmostlytrue 2 = true.

Proof. reflexivity. Qed.

Example override\_example4 : fmostlytrue 3 = false.

Proof. reflexivity. Qed.

Exercise: 1 star (override\_example) Before starting to work on the following proof, make sure you understand exactly what the theorem is saying and can paraphrase it in your own words. The proof itself is straightforward.

```
Theorem override_example : \forall (b:bool), (override (constfun b) 3 true) 2 = b. Proof.

Admitted.
```

We'll use function overriding heavily in parts of the rest of the course, and we will end up needing to know quite a bit about its properties. To prove these properties, though, we need to know about a few more of Coq's tactics; developing these is the main topic of the next chapter. For now, though, let's introduce just one very useful tactic that will also help us with proving properties of some of the other functions we have introduced in this chapter.

#### 35.4 The unfold Tactic

Sometimes, a proof will get stuck because Coq doesn't automatically expand a function call into its definition. (This is a feature, not a bug: if Coq automatically expanded everything possible, our proof goals would quickly become enormous – hard to read and slow for Coq to manipulate!)

```
Theorem unfold_example_bad : \forall m \ n, 3+n=m \rightarrow plus 3n+1=m+1. Proof. intros m \ n \ H. Abort.
```

The unfold tactic can be used to explicitly replace a defined name by the right-hand side of its definition.

```
Theorem unfold_example : \forall m \ n, 3+n=m \rightarrow \text{plus} 3 \ n+1=m+1.

Proof.

intros m \ n \ H.

unfold plus3.

rewrite \rightarrow H.

reflexivity. Qed.
```

Now we can prove a first property of override: If we override a function at some argument k and then look up k, we get back the overridden value.

```
Theorem override_eq : \forall \{X: \texttt{Type}\} \ x \ k \ (f: \texttt{nat} \rightarrow X), (override f \ k \ x) \ k = x.
```

```
Proof.
intros X \times k \cdot f.
unfold override.
rewrite \leftarrow beq\_nat\_refl.
reflexivity. Qed.
```

This proof was straightforward, but note that it requires unfold to expand the definition of override.

```
Exercise: 2 stars (override_neq) Theorem override_neq : \forall (X:Type) x1 x2 k1 k2 (f : nat \rightarrow X), f k1 = x1 \rightarrow beq_nat k2 k1 = false \rightarrow (override f k2 x2) k1 = x1. Proof.

Admitted.
```

As the inverse of unfold, Coq also provides a tactic fold, which can be used to "unexpand" a definition. It is used much less often.

#### 35.5 Additional Exercises

Exercise: 2 stars (fold\_length) Many common functions on lists can be implemented in terms of fold. For example, here is an alternative definition of length:

```
Definition fold_length \{X: \mathsf{Type}\}\ (l: \mathsf{list}\ X): \mathsf{nat} := \mathsf{fold}\ (\mathsf{fun}\ \_\ n \Rightarrow \mathsf{S}\ n)\ l\ 0.
Example test_fold_length1: fold_length [4;7;0] = 3.
Proof. reflexivity. Qed.

Prove the correctness of fold_length.

Theorem fold_length_correct: \forall\ X\ (l: \mathsf{list}\ X), \mathsf{fold_length}\ l = \mathsf{length}\ l.
Admitted.
```

Exercise: 3 stars (fold\_map) We can also define map in terms of fold. Finish fold\_map below

Write down a theorem in Coq stating that fold\_map is correct, and prove it.

# Chapter 36

# Library Lists

## 36.1 Lists: Working with Structured Data

Require Export Induction.

Module NATLIST.

#### 36.2 Pairs of Numbers

In an Inductive type definition, each constructor can take any number of arguments – none (as with true and O), one (as with S), or more than one, as in this definition:

```
Inductive natprod : Type := pair : nat \rightarrow nat \rightarrow natprod.
```

This declaration can be read: "There is just one way to construct a pair of numbers: by applying the constructor pair to two arguments of type **nat**."

We can construct an element of **natprod** like this:

```
Check (pair 35).
```

Here are two simple function definitions for extracting the first and second components of a pair. (The definitions also illustrate how to do pattern matching on two-argument constructors.)

```
Definition fst (p: \mathbf{natprod}): \mathbf{nat} := \max p \ \text{with} | pair x \ y \Rightarrow x end.

Definition snd (p: \mathbf{natprod}): \mathbf{nat} := \max p \ \text{with} | pair x \ y \Rightarrow y end.
```

Eval compute in (fst (pair 3 5)).

Since pairs are used quite a bit, it is nice to be able to write them with the standard mathematical notation (x,y) instead of pair xy. We can tell Coq to allow this with a Notation declaration.

```
Notation "(x, y)" := (pair x y).
```

The new notation can be used both in expressions and in pattern matches (indeed, we've seen it already in the previous chapter – this notation is provided as part of the standard library):

```
Eval compute in (fst (3,5)).

Definition fst' (p: \mathbf{natprod}) : \mathbf{nat} := 
   match p with
   | (x,y) \Rightarrow x
   end.

Definition snd' (p: \mathbf{natprod}) : \mathbf{nat} := 
   match p with
   | (x,y) \Rightarrow y
   end.

Definition swap_pair (p: \mathbf{natprod}) : \mathbf{natprod} := 
   match p with
   | (x,y) \Rightarrow (y,x)
   end.
```

Let's try and prove a few simple facts about pairs. If we state the lemmas in a particular (and slightly peculiar) way, we can prove them with just reflexivity (and its built-in simplification):

```
Theorem surjective_pairing': \forall (n \ m : nat), (n,m) = (fst \ (n,m), snd \ (n,m)).

Proof.

reflexivity. Qed.
```

Note that reflexivity is not enough if we state the lemma in a more natural way:

```
Theorem surjective_pairing_stuck : \forall (p : \mathbf{natprod}), p = (\mathsf{fst}\ p, \mathsf{snd}\ p). Proof. simpl. Abort.
```

We have to expose the structure of p so that simpl can perform the pattern match in fst and snd. We can do this with destruct.

Notice that, unlike for **nats**, **destruct** doesn't generate an extra subgoal here. That's because **natprod**s can only be constructed in one way.

```
Theorem surjective_pairing : \forall (p : natprod), p = (fst p, snd p).

Proof.

intros p. destruct p as [n \ m]. simpl. reflexivity. Qed.
```

```
Exercise: 1 star (snd_fst_is_swap) Theorem snd_fst_is_swap : \forall (p : natprod), (snd p, fst p) = swap_pair p.

Proof.

Admitted.

Exercise: 1 star, optional (fst_swap_is_snd) Theorem fst_swap_is_snd : \forall (p : natprod), fst (swap_pair p) = snd p.

Proof.

Admitted.

\square
```

#### 36.3 Lists of Numbers

Generalizing the definition of pairs a little, we can describe the type of *lists* of numbers like this: "A list is either the empty list or else a pair of a number and another list."

```
Inductive natlist : Type :=
  | nil : natlist
  | cons : nat → natlist → natlist.
  For example, here is a three-element list:
Definition mylist := cons 1 (cons 2 (cons 3 nil)).
```

As with pairs, it is more convenient to write lists in familiar programming notation. The following two declarations allow us to use :: as an infix cons operator and square brackets as an "outfix" notation for constructing lists.

```
Notation "x :: l" := (cons x l) (at level 60, right associativity). Notation "[]" := nil.
Notation "[x;..;y]" := (cons x.. (cons y nil)..).
```

It is not necessary to fully understand these declarations, but in case you are interested, here is roughly what's going on.

The right associativity annotation tells Coq how to parenthesize expressions involving several uses of :: so that, for example, the next three declarations mean exactly the same thing:

```
Definition mylist1 := 1 :: (2 :: (3 :: nil)).
Definition mylist2 := 1 :: 2 :: 3 :: nil.
Definition mylist3 := [1;2;3].
```

The at level 60 part tells Coq how to parenthesize expressions that involve both :: and some other infix operator. For example, since we defined + as infix notation for the plus function at level 50, Notation "x + y" := (plus x y) (at level 50, left associativity). The +

operator will bind tighter than ::, so 1 + 2 :: [3] will be parsed, as we'd expect, as (1 + 2) :: [3] rather than 1 + (2 :: [3]).

(By the way, it's worth noting in passing that expressions like "1 + 2 :: [3]" can be a little confusing when you read them in a .v file. The inner brackets, around 3, indicate a list, but the outer brackets, which are invisible in the HTML rendering, are there to instruct the "coqdoc" tool that the bracketed part should be displayed as Coq code rather than running text.)

The second and third Notation declarations above introduce the standard square-bracket notation for lists; the right-hand side of the third one illustrates Coq's syntax for declaring n-ary notations and translating them to nested sequences of binary constructors.

A number of functions are useful for manipulating lists. For example, the repeat function takes a number n and a count and returns a list of length count where every element is n.

```
Fixpoint repeat (n count : nat) : natlist :=
  match count with
  \mid 0 \Rightarrow \mathsf{nil}
  | S count' \Rightarrow n :: (repeat n count')
  end.
   The length function calculates the length of a list.
Fixpoint length (l:natlist) : nat :=
  \mathtt{match}\ l with
  \mid \mathsf{nil} \Rightarrow \mathsf{O}
  |h::t\Rightarrow S \text{ (length }t)
    The app ("append") function concatenates two lists.
Fixpoint app (l1 \ l2 : natlist) : natlist :=
  match l1 with
   nil \Rightarrow l2
  |h::t\Rightarrow h:: (app t l2)
  end.
    Actually, app will be used a lot in some parts of what follows, so it is convenient to have
an infix operator for it.
Notation "x ++ y" := (app x y)
                          (right associativity, at level 60).
Example test_app1: [1;2;3] ++ [4;5] = [1;2;3;4;5].
Proof. reflexivity. Qed.
Example test_app2: nil ++ [4;5] = [4;5].
Proof. reflexivity. Qed.
Example test_app3: [1;2;3] ++ nil = [1;2;3].
Proof. reflexivity. Qed.
```

Here are two smaller examples of programming with lists. The hd function returns the first element (the "head") of the list, while tl returns everything but the first element (the "tail"). Of course, the empty list has no first element, so we must pass a default value to be returned in that case.

Definition hd (default:nat) (l:natlist) : nat :=

```
\mathtt{match}\ l with
  | ni | \Rightarrow default
  |h::t\Rightarrow h
  end.
Definition tl (l:natlist) : natlist :=
  match l with
  \mathsf{nil}\Rightarrow\mathsf{nil}
  |h::t\Rightarrow t
  end.
Example test_hd1: hd 0 [1;2;3] = 1.
Proof. reflexivity. Qed.
Example test_hd2: hd 0 = 0.
Proof. reflexivity. Qed.
Example test_tl: tl [1;2;3] = [2;3].
Proof. reflexivity. Qed.
Exercise: 2 stars (list_funs) Complete the definitions of nonzeros, oddmembers and
countoddmembers below. Have a look at the tests to understand what these functions should
do.
Fixpoint nonzeros (l:natlist) : natlist :=
  admit.
Example test_nonzeros: nonzeros [0;1;0;2;3;0;0] = [1;2;3].
   Admitted.
Fixpoint oddmembers (l:natlist): natlist :=
  admit.
Example test_oddmembers: oddmembers [0;1;0;2;3;0;0] = [1;3].
   Admitted.
Fixpoint countoddmembers (l:natlist) : nat :=
  admit.
Example test_countoddmembers1: countoddmembers [1;0;3;1;4;5] = 4.
   Admitted.
Example test_countoddmembers2: countoddmembers [0;2;4] = 0.
   Admitted.
Example test_countoddmembers3: countoddmembers nil = 0.
   Admitted.
```

Exercise: 3 stars, advanced (alternate) Complete the definition of alternate, which "zips up" two lists into one, alternating between elements taken from the first list and elements from the second. See the tests below for more specific examples.

Note: one natural and elegant way of writing alternate will fail to satisfy Coq's requirement that all Fixpoint definitions be "obviously terminating." If you find yourself in this rut, look for a slightly more verbose solution that considers elements of both lists at the same time. (One possible solution requires defining a new kind of pairs, but this is not the only way.)

```
Fixpoint alternate (l1\ l2: natlist): natlist:= admit.

Example test_alternate1: alternate [1;2;3] [4;5;6] = [1;4;2;5;3;6]. Admitted.

Example test_alternate2: alternate [1] [4;5;6] = [1;4;5;6]. Admitted.

Example test_alternate3: alternate [1;2;3] [4] = [1;4;2;3]. Admitted.

Example test_alternate4: alternate [] [20;30] = [20;30]. Admitted.

\square
```

### 36.3.1 Bags via Lists

A bag (or *multiset*) is like a set, but each element can appear multiple times instead of just once. One reasonable implementation of bags is to represent a bag of numbers as a list.

```
Definition bag := natlist.
```

Exercise: 3 stars (bag\_functions) Complete the following definitions for the functions count, sum, add, and member for bags.

```
Fixpoint count (v:nat) (s:bag): nat :=
   admit.

All these proofs can be done just by reflexivity.
Example test_count1: count 1 [1;2;3;1;4;1] = 3.
   Admitted.
Example test_count2: count 6 [1;2;3;1;4;1] = 0.
   Admitted.
```

Multiset sum is similar to set *union*: sum a b contains all the elements of a and of b. (Mathematicians usually define *union* on multisets a little bit differently, which is why we don't use that name for this operation.) For sum we're giving you a header that does not

give explicit names to the arguments. Moreover, it uses the keyword Definition instead of Fixpoint, so even if you had names for the arguments, you wouldn't be able to process them recursively. The point of stating the question this way is to encourage you to think about whether sum can be implemented in another way – perhaps by using functions that have already been defined.

```
\texttt{Definition sum}: \texttt{bag} \to \texttt{bag} \to \texttt{bag} :=
  admit.
Example test_sum1: count 1 (sum [1;2;3] [1;4;1]) = 3.
   Admitted.
Definition add (v:nat) (s:bag) : bag :=
  admit.
Example test_add1: count 1 (add 1 [1;4;1]) = 3.
   Admitted.
Example test_add2: count 5 (add 1 [1;4;1]) = 0.
   Admitted.
Definition member (v:nat) (s:bag) : bool :=
  admit.
Example test_member1: member 1 [1;4;1] = \text{true}.
   Admitted.
Example test_member2: member 2[1;4;1] = false.
   Admitted.
   Exercise: 3 stars, optional (bag_more_functions) Here are some more bag functions
for you to practice with.
Fixpoint remove_one (v:nat) (s:bag) : bag :=
  admit.
Example test_remove_one1: count 5 (remove_one 5 [2;1;5;4;1]) = 0.
   Admitted.
Example test_remove_one2: count 5 (remove_one 5 [2;1;4;1]) = 0.
   Admitted.
Example test_remove_one3: count 4 (remove_one 5 [2;1;4;5;1;4]) = 2.
   Admitted.
Example test_remove_one4: count 5 (remove_one 5 [2;1;5;4;5;1;4]) = 1.
   Admitted.
Fixpoint remove_all (v:nat) (s:bag) : bag :=
  admit.
Example test_remove_all1: count 5 (remove_all 5 [2;1;5;4;1]) = 0.
```

```
Admitted.

Example test_remove_all2: count 5 (remove_all 5 [2;1;4;1]) = 0.

Admitted.

Example test_remove_all3: count 4 (remove_all 5 [2;1;4;5;1;4]) = 2.

Admitted.

Example test_remove_all4: count 5 (remove_all 5 [2;1;5;4;5;1;4;5;1;4]) = 0.

Admitted.

Fixpoint subset (s1:bag) (s2:bag): bool := admit.

Example test_subset1: subset [1;2] [2;1;4;1] = true.

Admitted.

Example test_subset2: subset [1;2;2] [2;1;4;1] = false.

Admitted.

\Box
```

Exercise: 3 stars (bag\_theorem) Write down an interesting theorem about bags involving the functions count and add, and prove it. Note that, since this problem is somewhat open-ended, it's possible that you may come up with a theorem which is true, but whose proof requires techniques you haven't learned yet. Feel free to ask for help if you get stuck!

36.4 Reasoning About Lists

Just as with numbers, simple facts about list-processing functions can sometimes be proved entirely by simplification. For example, the simplification performed by reflexivity is enough for this theorem...

```
Theorem nil_app : \forall l:natlist,

[] ++ l = l.

Proof. reflexivity. Qed.
```

... because the [] is substituted into the match position in the definition of app, allowing the match itself to be simplified.

Also, as with numbers, it is sometimes helpful to perform case analysis on the possible shapes (empty or non-empty) of an unknown list.

```
Theorem tl_length_pred : \forall l:natlist, pred (length l) = length (tl l).

Proof.

intros l. destruct l as [| n \ l'].

Case \ "l = nil".

reflexivity.

Case \ "l = cons \ n \ l'".
```

```
reflexivity. Qed.
```

Here, the nil case works because we've chosen to define tl nil = nil. Notice that the as annotation on the destruct tactic here introduces two names, n and l', corresponding to the fact that the cons constructor for lists takes two arguments (the head and tail of the list it is constructing).

Usually, though, interesting theorems about lists require induction for their proofs.

#### 36.4.1 Micro-Sermon

Simply reading example proofs will not get you very far! It is very important to work through the details of each one, using Coq and thinking about what each step of the proof achieves. Otherwise it is more or less guaranteed that the exercises will make no sense.

#### 36.4.2 Induction on Lists

Proofs by induction over datatypes like **natlist** are perhaps a little less familiar than standard natural number induction, but the basic idea is equally simple. Each **Inductive** declaration defines a set of data values that can be built up from the declared constructors: a boolean can be either true or false; a number can be either O or S applied to a number; a list can be either nil or cons applied to a number and a list.

Moreover, applications of the declared constructors to one another are the *only* possible shapes that elements of an inductively defined set can have, and this fact directly gives rise to a way of reasoning about inductively defined sets: a number is either O or else it is S applied to some *smaller* number; a list is either nil or else it is **cons** applied to some number and some *smaller* list; etc. So, if we have in mind some proposition P that mentions a list I and we want to argue that P holds for *all* lists, we can reason as follows:

- First, show that P is true of I when I is nil.
- Then show that P is true of I when I is cons n l' for some number n and some smaller list l', assuming that P is true for l'.

Since larger lists can only be built up from smaller ones, eventually reaching nil, these two things together establish the truth of P for all lists I. Here's a concrete example:

```
Theorem app_ass: \forall \ l1 \ l2 \ l3: natlist, (l1 ++ l2) ++ l3 = l1 ++ (l2 ++ l3). Proof. intros l1 \ l2 \ l3. induction l1 \ as \ [| \ n \ l1']. Case \ "l1 = nil". reflexivity. Case \ "l1 = cons \ n \ l1''. simpl. rewrite \rightarrow IHl1'. reflexivity. Qed.
```

Again, this Coq proof is not especially illuminating as a static written document – it is easy to see what's going on if you are reading the proof in an interactive Coq session and you can see the current goal and context at each point, but this state is not visible in the written-down parts of the Coq proof. So a natural-language proof – one written for human readers – will need to include more explicit signposts; in particular, it will help the reader stay oriented if we remind them exactly what the induction hypothesis is in the second case.

Theorem: For all lists l1, l2, and l3, (l1 ++ l2) ++ l3 = l1 ++ (l2 ++ l3). Proof: By induction on l1.

- First, suppose l1 = []. We must show  $(\Box ++ 12) ++ 13 = \Box ++ (12 ++ 13)$ , which follows directly from the definition of ++.
- Next, suppose l1 = n:: l1', with (l1' ++ l2) ++ l3 = l1' ++ (l2 ++ l3) (the induction hypothesis). We must show ((n:: l1') ++ l2) ++ l3 = (n:: l1') ++ (l2 ++ l3).

]] By the definition of ++, this follows from n :: ((l1'++l2)++l3) = n :: (l1'++(l2++l3)), which is immediate from the induction hypothesis.  $\square$ 

Here is a similar example to be worked together in class:

```
Theorem app_length: \forall \ l1 \ l2 : \mathbf{natlist}, length (l1 ++ l2) = (\mathsf{length} \ l1) + (\mathsf{length} \ l2). Proof.

intros l1 \ l2. induction l1 \ \mathsf{as} \ [| \ n \ l1'].

Case \ "l1 = \mathsf{nil}".

reflexivity.

Case \ "l1 = \mathsf{cons}".

simpl. rewrite \to \mathit{IHl1'}. reflexivity. Qed.
```

For a slightly more involved example of an inductive proof over lists, suppose we define a "cons on the right" function snoc like this...

```
Fixpoint snoc (l:\mathbf{natlist}) (v:\mathbf{nat}): \mathbf{natlist} :=  \mathbf{match}\ l with | \ \mathsf{nil} \Rightarrow [v]  | \ h :: t \Rightarrow h :: (\mathsf{snoc}\ t\ v)  end.
```

... and use it to define a list-reversing function rev like this:

```
Fixpoint rev (l:\mathbf{natlist}):\mathbf{natlist}:=
\mathsf{match}\ l\ \mathsf{with}
|\ \mathsf{nil}\Rightarrow \mathsf{nil}
|\ h::t\Rightarrow \mathsf{snoc}\ (\mathsf{rev}\ t)\ h
\mathsf{end}.
Example test_rev1: rev [1;2;3]=[3;2;1].
Proof. reflexivity. Qed.
```

```
Example test_rev2: rev nil = nil. Proof. reflexivity. Qed.
```

Now let's prove some more list theorems using our newly defined **snoc** and **rev**. For something a little more challenging than the inductive proofs we've seen so far, let's prove that reversing a list does not change its length. Our first attempt at this proof gets stuck in the successor case...

```
Theorem rev_length_firsttry : \forall \ l : natlist, length (rev l) = length l.

Proof.

intros l. induction l as [|\ n\ l'].

Case\ "l = []".

reflexivity.

Case\ "l = n :: l'".

simpl.

rewrite \leftarrow IHl'.

Abort.
```

So let's take the equation about **snoc** that would have enabled us to make progress and prove it as a separate lemma.

```
Theorem length_snoc : \forall n : \mathbf{nat}, \forall l : \mathbf{natlist}, length (snoc l n) = \mathbf{S} (length l).

Proof.

intros n l. induction l as [|n'l'].

Case "l = nil".

reflexivity.

Case "l = cons n' l'".

simpl. rewrite \rightarrow IHl'. reflexivity. Qed.
```

Note that we make the lemma as *general* as possible: in particular, we quantify over *all* **natlists**, not just those that result from an application of **rev**. This should seem natural, because the truth of the goal clearly doesn't depend on the list having been reversed. Moreover, it is much easier to prove the more general property.

Now we can complete the original proof.

```
Theorem rev_length : \forall \ l : natlist, length (rev l) = length l.

Proof.

intros l. induction l as [|\ n\ l'].

Case\ "l = nil".

reflexivity.

Case\ "l = cons".

simpl. rewrite \rightarrow length_snoc.

rewrite \rightarrow IHl'. reflexivity. Qed.
```

For comparison, here are informal proofs of these two theorems:

Theorem: For all numbers n and lists l, length (snoc l n) = S (length l). Proof: By induction on l.

- First, suppose I = []. We must show length (snoc  $\square$  n) = S (length  $\square$ ), which follows directly from the definitions of length and snoc.
- Next, suppose l = n'::l', with length (snoc l' n) = S (length l'). We must show length (snoc (n' :: l') n) = S (length (n' :: l')). By the definitions of length and snoc, this follows from S (length (snoc l' n)) = S (S (length l')),

]] which is immediate from the induction hypothesis.  $\Box$  *Theorem*: For all lists I, length (rev I) = length I. *Proof*: By induction on I.

- First, suppose I = []. We must show length (rev  $\square$ ) = length  $\square$ , which follows directly from the definitions of length and rev.
- Next, suppose I = n::l', with length (rev l') = length l'. We must show length (rev (n :: l')) = length (n :: l'). By the definition of rev, this follows from length (snoc (rev l') n) = S (length l') which, by the previous lemma, is the same as S (length (rev l')) = S (length l'). This is immediate from the induction hypothesis. □

Obviously, the style of these proofs is rather longwinded and pedantic. After the first few, we might find it easier to follow proofs that give fewer details (since we can easily work them out in our own minds or on scratch paper if necessary) and just highlight the non-obvious steps. In this more compressed style, the above proof might look more like this:

Theorem: For all lists I, length (rev I) = length I.

*Proof*: First, observe that length (snoc l n) = S (length l) for any l. This follows by a straightforward induction on l. The main property now follows by another straightforward induction on l, using the observation together with the induction hypothesis in the case where l = n'::l'.  $\square$ 

Which style is preferable in a given situation depends on the sophistication of the expected audience and on how similar the proof at hand is to ones that the audience will already be familiar with. The more pedantic style is a good default for present purposes.

#### 36.4.3 SearchAbout

We've seen that proofs can make use of other theorems we've already proved, using rewrite, and later we will see other ways of reusing previous theorems. But in order to refer to a theorem, we need to know its name, and remembering the names of all the theorems we might ever want to use can become quite difficult! It is often hard even to remember what theorems have been proven, much less what they are named.

Coq's SearchAbout command is quite helpful with this. Typing SearchAbout foo will cause Coq to display a list of all theorems involving foo. For example, try uncommenting the following to see a list of theorems that we have proved about rev:

Keep SearchAbout in mind as you do the following exercises and throughout the rest of the course; it can save you a lot of time!

#### 36.4.4 List Exercises, Part 1

```
Exercise: 3 stars (list_exercises) More practice with lists.
Theorem app_nil_end : \forall l : natlist,
  l ++ [] = l.
Proof.
   Admitted.
Theorem rev_involutive : \forall l : natlist,
  rev (rev l) = l.
Proof.
   Admitted.
   There is a short solution to the next exercise. If you find yourself getting tangled up,
step back and try to look for a simpler way.
Theorem app_ass4 : \forall l1 l2 l3 l4 : natlist,
  l1 ++ (l2 ++ (l3 ++ l4)) = ((l1 ++ l2) ++ l3) ++ l4.
Proof.
   Admitted.
Theorem snoc_append : \forall (l:natlist) (n:nat),
  snoc l n = l ++ [n].
Proof.
   Admitted.
Theorem distr_rev : \forall l1 l2 : natlist,
  rev (l1 ++ l2) = (rev l2) ++ (rev l1).
Proof.
   Admitted.
   An exercise about your implementation of nonzeros:
Lemma nonzeros_app : \forall l1 l2 : natlist,
  nonzeros (l1 ++ l2) = (nonzeros l1) ++ (nonzeros l2).
Proof.
   Admitted.
```

#### 36.4.5 List Exercises, Part 2

Exercise: 2 stars (list\_design) Design exercise:

• Write down a non-trivial theorem involving cons (::), snoc, and app (++).

• Prove it.

Exercise: 3 stars, advanced (bag\_proofs) Here are a couple of little theorems to prove about your definitions about bags in the previous problem.

```
Theorem count_member_nonzero : \forall (s : bag),
  ble_nat 1 (count 1 (1 :: s)) = true.
Proof.
   Admitted.
   The following lemma about ble_nat might help you in the next proof.
Theorem ble_n_Sn : \forall n,
  ble_nat n (S n) = true.
Proof.
  intros n. induction n as [\mid n'].
  Case "0".
    simpl. reflexivity.
  Case "S n'".
    simpl. rewrite IHn'. reflexivity. Qed.
Theorem remove_decreases_count: \forall (s : bag),
  ble_nat (count 0 (remove_one 0 s)) (count 0 s) = true.
Proof.
   Admitted.
```

Exercise: 3 stars, optional (bag\_count\_sum) Write down an interesting theorem about bags involving the functions count and sum, and prove it.

Exercise: 4 stars, advanced (rev\_injective) Prove that the rev function is injective, that is,

```
for
all (l1 l2 : natlist), rev l1 = rev l2 -> l1 = l2. There is a hard way and an easy way to solve this exercise.
 \Box
```

## 36.5 Options

Here is another type definition that is often useful in day-to-day programming:

```
Inductive natoption: Type :=
```

```
Some : nat \rightarrow natoption
None : natoption.
```

One use of **natoption** is as a way of returning "error codes" from functions. For example, suppose we want to write a function that returns the **n**th element of some list. If we give it type  $\mathbf{nat} \to \mathbf{natlist} \to \mathbf{nat}$ , then we'll have to return some number when the list is too short!

```
Fixpoint index_bad (n:\mathbf{nat}) (l:\mathbf{natlist}) : \mathbf{nat} :=  match l with | \ \mathsf{nil} \Rightarrow 42  | \ a :: \ l' \Rightarrow \mathsf{match} \ \mathsf{beq\_nat} \ n \ \mathsf{O} \ \mathsf{with}  | \ \mathsf{true} \Rightarrow a  | \ \mathsf{false} \Rightarrow \mathsf{index\_bad} \ (\mathsf{pred} \ n) \ l'  end end.
```

On the other hand, if we give it type  $nat \to natlist \to natoption$ , then we can return None when the list is too short and Some a when the list has enough members and a appears at position n.

```
Fixpoint index (n:\mathbf{nat}) (l:\mathbf{natlist}): \mathbf{natoption}:= \mathbf{match}\ l with |\ \mathsf{nil}\ \Rightarrow\ \mathsf{None}\ |\ a::\ l'\ \Rightarrow\ \mathsf{match}\ \mathsf{beq\_nat}\ n O with |\ \mathsf{true}\ \Rightarrow\ \mathsf{Some}\ a |\ \mathsf{false}\ \Rightarrow\ \mathsf{index}\ (\mathsf{pred}\ n)\ l' |\ \mathsf{end}\ \mathsf{end}\ end. Example test_index1: |\ \mathsf{index}\ 0\ [4;5;6;7]\ =\ \mathsf{Some}\ 4. Proof. |\ \mathsf{reflexivity}\ \mathsf{Qed}\ Example test_index2: |\ \mathsf{index}\ 3\ [4;5;6;7]\ =\ \mathsf{Some}\ 7. Proof. |\ \mathsf{reflexivity}\ \mathsf{Qed}\ Example test_index3: |\ \mathsf{index}\ 10\ [4;5;6;7]\ =\ \mathsf{None}\ Proof. |\ \mathsf{reflexivity}\ \mathsf{Qed}\ Example test_index3: |\ \mathsf{index}\ 10\ [4;5;6;7]\ =\ \mathsf{None}\ Proof. |\ \mathsf{reflexivity}\ \mathsf{Qed}\
```

This example is also an opportunity to introduce one more small feature of Coq's programming language: conditional expressions...

```
Fixpoint index' (n:\mathsf{nat}) (l:\mathsf{natlist}): \mathsf{natoption} := \mathsf{match}\ l with |\mathsf{nil}| \Rightarrow \mathsf{None} |\ a :: \ l' \Rightarrow \mathsf{if}\ \mathsf{beq\_nat}\ n O then Some a else index' (\mathsf{pred}\ n)\ l' end.
```

Coq's conditionals are exactly like those found in any other language, with one small generalization. Since the boolean type is not built in, Coq actually allows conditional expressions over *any* inductively defined type with exactly two constructors. The guard is

considered true if it evaluates to the first constructor in the Inductive definition and false if it evaluates to the second.

The function below pulls the **nat** out of a **natoption**, returning a supplied default in the None case.

```
\begin{array}{l} {\rm Definition\ option\_elim\ }(d:{\bf nat})\ (o:{\bf natoption}):{\bf nat}:=\\ {\rm match\ }o\ {\rm with}\\ {\rm |\ Some\ }n'\Rightarrow n'\\ {\rm |\ None}\Rightarrow d\\ {\rm end.} \end{array}
```

Exercise: 2 stars (hd\_opt) Using the same idea, fix the hd function from earlier so we don't have to pass a default element for the nil case.

```
Definition hd_opt (l: natlist): natoption := admit.

Example test_hd_opt1: hd_opt [] = None.
    Admitted.

Example test_hd_opt2: hd_opt [1] = Some 1.
    Admitted.

Example test_hd_opt3: hd_opt [5;6] = Some 5.
    Admitted.
```

Exercise: 1 star, optional (option\_elim\_hd) This exercise relates your new hd\_opt to the old hd.

```
Theorem option_elim_hd : \forall (l:natlist) (default:nat), hd default l = option_elim default (hd_opt l).

Proof.

Admitted.
```

```
Fixpoint beq_natlist (l1 l2 : natlist) : bool :=
   admit.

Example test_beq_natlist1 : (beq_natlist nil nil = true).
   Admitted.

Example test_beq_natlist2 : beq_natlist [1;2;3] [1;2;3] = true.
   Admitted.

Example test_beq_natlist3 : beq_natlist [1;2;3] [1;2;4] = false.
   Admitted.
```

```
Theorem beq_natlist_refl : \forall l:natlist, true = beq_natlist l l.

Proof.

Admitted.
```

#### 36.6 Dictionaries

As a final illustration of how fundamental data structures can be defined in Coq, here is the declaration of a simple **dictionary** data type, using numbers for both the keys and the values stored under these keys. (That is, a dictionary represents a finite map from numbers to numbers.)

Module DICTIONARY.

```
Inductive dictionary : Type :=
    | empty : dictionary
    | record : nat → nat → dictionary → dictionary.
```

This declaration can be read: "There are two ways to construct a **dictionary**: either using the constructor **empty** to represent an empty dictionary, or by applying the constructor **record** to a key, a value, and an existing **dictionary** to construct a **dictionary** with an additional key to value mapping."

```
Definition insert (key \ value : nat) \ (d : dictionary) : dictionary := (record <math>key \ value \ d).
```

Here is a function find that searches a **dictionary** for a given key. It evaluates evaluates to None if the key was not found and Some val if the key was mapped to val in the dictionary. If the same key is mapped to multiple values, find will return the first one it finds.

```
Fixpoint find (key: \mathbf{nat}) (d: \mathbf{dictionary}): \mathbf{natoption} :=  match d with | empty \Rightarrow None | record k v d ' \Rightarrow if (\mathsf{beq\_nat}\ key\ k) then (\mathsf{Some}\ v) else (\mathsf{find}\ key\ d ') end.
```

Exercise: 1 star (dictionary\_invariant1) Complete the following proof.

```
Theorem dictionary_invariant1': \forall (d: dictionary) (k v: nat), (find k (insert k v d)) = Some v.

Proof.

Admitted.
```

Exercise: 1 star (dictionary\_invariant2) Complete the following proof.

```
Theorem dictionary_invariant2': \forall (d: dictionary) (m n o: nat), beq_nat m n = false \rightarrow find m d = find m (insert n o d). Proof.

Admitted.
```

End DICTIONARY.

End NATLIST.

# Chapter 37

# Library Induction

## 37.1 Induction: Proof by Induction

The next line imports all of our definitions from the previous chapter.

Require Export Basics.

For it to work, you need to use *coqc* to compile *Basics.v* into *Basics.vo*. (This is like making a .class file from a .java file, or a .o file from a .c file.)

Here are two ways to compile your code:

• CoqIDE:

Open Basics.v. In the "Compile" menu, click on "Compile Buffer".

• Command line:

Run coqc Basics.v

## 37.2 Naming Cases

The fact that there is no explicit command for moving from one branch of a case analysis to the next can make proof scripts rather hard to read. In larger proofs, with nested case analyses, it can even become hard to stay oriented when you're sitting with Coq and stepping through the proof. (Imagine trying to remember that the first five subgoals belong to the inner case analysis and the remaining seven cases are what remains of the outer one...) Disciplined use of indentation and comments can help, but a better way is to use the *Case* tactic.

```
Require String. Open Scope string\_scope.

Ltac move\_to\_top \ x :=
match reverse goal with
```

```
\mid H: \_ \vdash \_ \Rightarrow \mathsf{try} \; \mathsf{move} \; x \; \mathsf{after} \; H
  end.
Tactic Notation "assert_eq" ident(x) constr(v) :=
  let H := fresh in
  assert (x = v) as H by reflexivity;
  clear H.
Tactic Notation "Case_aux" ident(x) constr(name) :=
  first |
    set (x := name); move\_to\_top x
   assert_eq x name; move_to_top x
   fail 1 "because we are working on a different case" ].
Tactic Notation "Case" constr(name) := Case\_aux \ Case \ name.
Tactic Notation "SCase" constr(name) := Case\_aux \ SCase \ name.
Tactic Notation "SSCase" constr(name) := Case\_aux SSCase name.
Tactic Notation "SSSCase" constr(name) := Case\_aux SSSCase name.
Tactic Notation "SSSSCase" constr(name) := Case\_aux SSSSCase name.
Tactic Notation "SSSSSCase" constr(name) := Case\_aux SSSSCase name.
Tactic Notation "SSSSSSCase" constr(name) := Case\_aux SSSSSSCase name.
Tactic Notation "SSSSSSCase" constr(name) := Case\_aux SSSSSSCase name.
   Here's an example of how Case is used. Step through the following proof and observe
how the context changes.
Theorem andb_true_elim1 : \forall b \ c : \mathbf{bool},
  andb b c = true \rightarrow b = true.
Proof.
  intros b c H.
  destruct b.
  Case "b = true".
                        reflexivity.
  Case "b = false".
                        rewrite \leftarrow H.
    reflexivity.
Qed.
```

Case does something very straightforward: It simply adds a string that we choose (tagged with the identifier "Case") to the context for the current goal. When subgoals are generated, this string is carried over into their contexts. When the last of these subgoals is finally proved and the next top-level goal becomes active, this string will no longer appear in the context and we will be able to see that the case where we introduced it is complete. Also, as a sanity check, if we try to execute a new Case tactic while the string left by the previous one is still in the context, we get a nice clear error message.

For nested case analyses (e.g., when we want to use a destruct to solve a goal that has itself been generated by a destruct), there is an SCase ("subcase") tactic.

Exercise: 2 stars (andb\_true\_elim2) Prove andb\_true\_elim2, marking cases (and subcases) when you use destruct.

```
Theorem andb_true_elim2 : \forall b \ c : bool, andb b \ c = true \rightarrow c = true. Proof. Admitted.
```

There are no hard and fast rules for how proofs should be formatted in Coq – in particular, where lines should be broken and how sections of the proof should be indented to indicate their nested structure. However, if the places where multiple subgoals are generated are marked with explicit *Case* tactics placed at the beginning of lines, then the proof will be readable almost no matter what choices are made about other aspects of layout.

This is a good place to mention one other piece of (possibly obvious) advice about line lengths. Beginning Coq users sometimes tend to the extremes, either writing each tactic on its own line or entire proofs on one line. Good style lies somewhere in the middle. In particular, one reasonable convention is to limit yourself to 80-character lines. Lines longer than this are hard to read and can be inconvenient to display and print. Many editors have features that help enforce this.

## 37.3 Proof by Induction

We proved in the last chapter that 0 is a neutral element for + on the left using a simple argument. The fact that it is also a neutral element on the right...

```
Theorem plus_0_r_firsttry : \forall n:nat,
 n + 0 = n.
```

... cannot be proved in the same simple way. Just applying reflexivity doesn't work: the n in n + 0 is an arbitrary unknown number, so the match in the definition of + can't be simplified.

```
Proof. intros n. simpl. Abort.
```

And reasoning by cases using destruct n doesn't get us much further: the branch of the case analysis where we assume n = 0 goes through, but in the branch where n = S n' for some n' we get stuck in exactly the same way. We could use destruct n' to get one step further, but since n can be arbitrarily large, if we try to keep on like this we'll never be done.

```
Theorem plus_0_r_secondtry : \forall n:nat,

n + 0 = n.

Proof.

intros n. destruct n as [\mid n'].
```

```
Case "n = 0". reflexivity. Case "n = S n'". simpl. Abort.
```

To prove such facts – indeed, to prove most interesting facts about numbers, lists, and other inductively defined sets – we need a more powerful reasoning principle: *induction*.

Recall (from high school) the principle of induction over natural numbers: If P(n) is some proposition involving a natural number n and we want to show that P holds for  $\mathit{all}$  numbers n, we can reason like this:

- show that P(O) holds;
- show that, for any n', if P(n') holds, then so does P(S n');
- conclude that P(n) holds for all n.

In Coq, the steps are the same but the order is backwards: we begin with the goal of proving P(n) for all n and break it down (by applying the induction tactic) into two separate subgoals: first showing P(0) and then showing  $P(n') \to P(S n')$ . Here's how this works for the theorem we are trying to prove at the moment:

```
Theorem plus_0_r: \forall n:nat, n + 0 = n.

Proof.

intros n. induction n as [\mid n'].

Case \text{"} n = 0 \text{". reflexivity.}

Case \text{"} n = S \text{ n'". simpl. rewrite} \rightarrow IHn'. \text{ reflexivity.} Qed.
```

Like destruct, the induction tactic takes an as... clause that specifies the names of the variables to be introduced in the subgoals. In the first branch,  $\mathbf{n}$  is replaced by 0 and the goal becomes 0 + 0 = 0, which follows by simplification. In the second,  $\mathbf{n}$  is replaced by  $\mathbf{S}$  n' and the assumption n' + 0 = n' is added to the context (with the name IHn', i.e., the Induction Hypothesis for n'). The goal in this case becomes  $(\mathbf{S} \ n') + 0 = \mathbf{S} \ n'$ , which simplifies to  $\mathbf{S}$   $(n' + 0) = \mathbf{S} \ n'$ , which in turn follows from the induction hypothesis.

```
Theorem minus_diag : \forall n, minus n n = 0.

Proof.

intros n. induction n as [\mid n'].

Case \text{"} n = 0\text{"}.

simpl. reflexivity.

Case \text{"} n = S \text{ n'"}.

simpl. rewrite \rightarrow IHn'. reflexivity. Qed.
```

Exercise: 2 stars (basic\_induction) Prove the following lemmas using induction. You might need previously proven results.

```
Theorem mult_0_r : \forall n:nat,
```

```
Proof.
   Admitted.
Theorem plus_n_Sm : \forall n \ m : nat,
  S(n+m) = n + (Sm).
Proof.
    Admitted.
Theorem plus_comm : \forall n m : nat,
  n + m = m + n.
Proof.
    Admitted.
Theorem plus_assoc : \forall n m p : nat,
  n + (m + p) = (n + m) + p.
Proof.
    Admitted.
   Exercise: 2 stars (double_plus) Consider the following function, which doubles its
argument:
Fixpoint double (n:nat) :=
  {\tt match}\ n\ {\tt with}
  | 0 \Rightarrow 0
  | S n' \Rightarrow S (S (double n'))
   Use induction to prove this simple fact about double:
Lemma double_plus : \forall n, double n = n + n.
Proof.
    Admitted.
```

## 37.4 Proofs Within Proofs

destruct and induction.

 $n \times 0 = 0$ .

In Coq, as in informal mathematics, large proofs are very often broken into a sequence of theorems, with later proofs referring to earlier theorems. Occasionally, however, a proof will need some miscellaneous fact that is too trivial (and of too little general interest) to bother giving it its own top-level name. In such cases, it is convenient to be able to simply state

Exercise: 1 star (destruct\_induction) Briefly explain the difference between the tactics

and prove the needed "sub-theorem" right at the point where it is used. The assert tactic allows us to do this. For example, our earlier proof of the mult\_0\_plus theorem referred to a previous theorem named plus\_0\_n. We can also use assert to state and prove plus\_0\_n in-line:

```
Theorem mult_0_plus': \forall n \ m: nat, (0+n) \times m = n \times m.

Proof.

intros n \ m.

assert (H: 0+n=n).

Case "Proof of assertion". reflexivity. rewrite \rightarrow H.

reflexivity. Qed.
```

The assert tactic introduces two sub-goals. The first is the assertion itself; by prefixing it with H: we name the assertion H. (Note that we could also name the assertion with as just as we did above with destruct and induction, i.e., assert (0 + n = n) as H. Also note that we mark the proof of this assertion with a Case, both for readability and so that, when using Coq interactively, we can see when we're finished proving the assertion by observing when the "Proof of assertion" string disappears from the context.) The second goal is the same as the one at the point where we invoke assert, except that, in the context, we have the assumption H that 0 + n = n. That is, assert generates one subgoal where we must prove the asserted fact and a second subgoal where we can use the asserted fact to make progress on whatever we were trying to prove in the first place.

Actually, assert will turn out to be handy in many sorts of situations. For example, suppose we want to prove that (n + m) + (p + q) = (m + n) + (p + q). The only difference between the two sides of the = is that the arguments m and n to the first inner + are swapped, so it seems we should be able to use the commutativity of addition (plus\_comm) to rewrite one into the other. However, the rewrite tactic is a little stupid about where it applies the rewrite. There are three uses of + here, and it turns out that doing rewrite  $\rightarrow$  plus\_comm will affect only the outer one.

```
Theorem plus_rearrange_firsttry : \forall n \ m \ p \ q : nat, (n+m)+(p+q)=(m+n)+(p+q). Proof. intros n \ m \ p \ q. rewrite \rightarrow plus\_comm. Abort.
```

To get  $plus\_comm$  to apply at the point where we want it, we can introduce a local lemma stating that n + m = m + n (for the particular m and n that we are talking about here), prove this lemma using  $plus\_comm$ , and then use this lemma to do the desired rewrite.

```
Theorem plus_rearrange : \forall n \ m \ p \ q : \mathsf{nat}, (n+m) + (p+q) = (m+n) + (p+q). Proof.
```

```
intros n m p q.

assert (H: n + m = m + n).

Case "Proof of assertion".

rewrite \rightarrow plus\_comm. reflexivity.

rewrite \rightarrow H. reflexivity. Qed.
```

Exercise: 4 stars (mult\_comm) Use assert to help prove this theorem. You shouldn't need to use induction.

```
Theorem plus_swap : \forall n \ m \ p : nat,
 n + (m + p) = m + (n + p).
Proof.
Admitted.
```

Now prove commutativity of multiplication. (You will probably need to define and prove a separate subsidiary theorem to be used in the proof of this one.) You may find that plus\_swap comes in handy.

```
Theorem mult_comm : \forall m \ n : nat, m \times n = n \times m.

Proof.

Admitted.
```

Exercise: 2 stars, optional (evenb\_n\_oddb\_Sn) Prove the following simple fact:

```
Theorem evenb_n_oddb_Sn : \forall n : \mathbf{nat}, evenb n = \text{negb} (evenb (S n)).

Proof.

Admitted.
```

### 37.5 More Exercises

Exercise: 3 stars, optional (more\_exercises) Take a piece of paper. For each of the following theorems, first *think* about whether (a) it can be proved using only simplification and rewriting, (b) it also requires case analysis (destruct), or (c) it also requires induction. Write down your prediction. Then fill in the proof. (There is no need to turn in your piece of paper; this is just to encourage you to reflect before hacking!)

```
Theorem ble_nat_refl : \forall n:nat,
true = ble_nat n n.
Proof.
Admitted.
Theorem zero_nbeg_S : \forall n:nat,
```

```
beq_nat 0 (S n) = false.
Proof.
    Admitted.
Theorem and b_{false_r} : \forall b : bool,
  andb b false = false.
Proof.
    Admitted.
Theorem plus_ble_compat_l : \forall n \ m \ p : nat,
  ble_nat n m = true \rightarrow ble_nat (p + n) (p + m) = true.
Proof.
    Admitted.
Theorem S_nbeq_0 : \forall n:nat,
  beq_nat (S n) 0 = false.
Proof.
    Admitted.
Theorem mult_1_I : \forall n:nat, 1 \times n = n.
    Admitted.
Theorem all3_spec : \forall b \ c : \mathbf{bool},
     orb
        (andb b c)
        (orb (negb b)
                    (negb c)
  = true.
Proof.
    Admitted.
Theorem mult_plus_distr_r : \forall n \ m \ p : nat,
   (n+m)\times p=(n\times p)+(m\times p).
Proof.
    Admitted.
Theorem mult_assoc : \forall n \ m \ p : nat,
  n \times (m \times p) = (n \times m) \times p.
Proof.
    Admitted.
```

Exercise: 2 stars, optional (beq\_nat\_refl) Prove the following theorem. Putting true on the left-hand side of the equality may seem odd, but this is how the theorem is stated in the standard library, so we follow suit. Since rewriting works equally well in either direction, we will have no problem using the theorem no matter which way we state it.

```
Theorem beg_nat_refl : \forall n : nat,
  true = beg_nat n n.
Proof.
   Admitted.
```

Exercise: 2 stars, optional (plus\_swap') The replace tactic allows you to specify a particular subterm to rewrite and what you want it rewritten to. More precisely, replace (t) with (u) replaces (all copies of) expression t in the goal by expression u, and generates t = u as an additional subgoal. This is often useful when a plain rewrite acts on the wrong part of the goal.

Use the replace tactic to do a proof of plus\_swap', just like plus\_swap but without needing assert (n + m = m + n).

```
Theorem plus_swap' : \forall n \ m \ p : nat,
  n + (m + p) = m + (n + p).
Proof.
   Admitted.
```

Exercise: 3 stars (binary\_commute) Recall the increment and binary-to-unary functions that you wrote for the binary exercise in the Basics chapter. Prove that these functions commute – that is, incrementing a binary number and then converting it to unary yields the same result as first converting it to unary and then incrementing.

(Before you start working on this exercise, please copy the definitions from your solution to the binary exercise here so that this file can be graded on its own. If you find yourself wanting to change your original definitions to make the property easier to prove, feel free to do so.)

Exercise: 5 stars, advanced (binary\_inverse) This exercise is a continuation of the

previous exercise about binary numbers. You will need your definitions and theorems from the previous exercise to complete this one.

- (a) First, write a function to convert natural numbers to binary numbers. Then prove that starting with any natural number, converting to binary, then converting back yields the same natural number you started with.
- (b) You might naturally think that we should also prove the opposite direction: that starting with a binary number, converting to a natural, and then back to binary yields the same number we started with. However, it is not true! Explain what the problem is.
- (c) Define a function *normalize* from binary numbers to binary numbers such that for any binary number b, converting to a natural and then back to binary yields (normalize b). Prove it.

Again, feel free to change your earlier definitions if this helps here.

### 37.6 Advanced Material

### 37.6.1 Formal vs. Informal Proof

"Informal proofs are algorithms; formal proofs are code."

The question of what, exactly, constitutes a "proof" of a mathematical claim has challenged philosophers for millenia. A rough and ready definition, though, could be this: a proof of a mathematical proposition P is a written (or spoken) text that instills in the reader or hearer the certainty that P is true. That is, a proof is an act of communication.

Now, acts of communication may involve different sorts of readers. On one hand, the "reader" can be a program like Coq, in which case the "belief" that is instilled is a simple mechanical check that P can be derived from a certain set of formal logical rules, and the proof is a recipe that guides the program in performing this check. Such recipes are *formal* proofs.

Alternatively, the reader can be a human being, in which case the proof will be written in English or some other natural language, thus necessarily *informal*. Here, the criteria for success are less clearly specified. A "good" proof is one that makes the reader believe P. But the same proof may be read by many different readers, some of whom may be convinced by a particular way of phrasing the argument, while others may not be. One reader may be particularly pedantic, inexperienced, or just plain thick-headed; the only way to convince them will be to make the argument in painstaking detail. But another reader, more familiar in the area, may find all this detail so overwhelming that they lose the overall thread. All they want is to be told the main ideas, because it is easier to fill in the details for themselves. Ultimately, there is no universal standard, because there is no single way of writing an informal proof that is guaranteed to convince every conceivable reader. In practice, however, mathematicians have developed a rich set of conventions and idioms for writing about complex mathematical objects that, within a certain community, make communication fairly reliable. The conventions of this stylized form of communication give a fairly clear standard for judging proofs good or bad.

Because we are using Coq in this course, we will be working heavily with formal proofs. But this doesn't mean we can ignore the informal ones! Formal proofs are useful in many ways, but they are *not* very efficient ways of communicating ideas between human beings.

For example, here is a proof that addition is associative:

```
Theorem plus_assoc' : \forall n \ m \ p : \mathbf{nat}, n + (m + p) = (n + m) + p.

Proof. intros n \ m \ p. induction n as [| \ n']. reflexivity. simpl. rewrite \rightarrow \mathit{IHn'}. reflexivity. Qed.
```

Cog is perfectly happy with this as a proof. For a human, however, it is difficult to make

much sense of it. If you're used to Coq you can probably step through the tactics one after the other in your mind and imagine the state of the context and goal stack at each point, but if the proof were even a little bit more complicated this would be next to impossible. Instead, a mathematician might write it something like this:

- Theorem: For any n, m and p, n + (m + p) = (n + m) + p. Proof: By induction on n.
  - First, suppose n = 0. We must show 0 + (m + p) = (0 + m) + p. This follows directly from the definition of +.
  - Next, suppose n = S n', where n' + (m + p) = (n' + m) + p. We must show (S n') + (m + p) = ((S n') + m) + p. By the definition of +, this follows from S(n' + (m + p)) = S((n' + m) + p), which is immediate from the induction hypothesis.  $\square$

The overall form of the proof is basically similar. This is no accident: Coq has been designed so that its induction tactic generates the same sub-goals, in the same order, as the bullet points that a mathematician would write. But there are significant differences of detail: the formal proof is much more explicit in some ways (e.g., the use of reflexivity) but much less explicit in others (in particular, the "proof state" at any given point in the Coq proof is completely implicit, whereas the informal proof reminds the reader several times where things stand).

Here is a formal proof that shows the structure more clearly:

```
Theorem plus_assoc'': \forall \ n \ m \ p: nat, n + (m + p) = (n + m) + p.

Proof.

intros n \ m \ p. induction n as [|\ n'].

Case \ "n = 0".

reflexivity.

Case \ "n = S \ n'".

simpl. rewrite \rightarrow IHn'. reflexivity. Qed.
```

Exercise: 2 stars, advanced (plus\_comm\_informal) Translate your solution for plus\_comm into an informal proof.

```
Theorem: Addition is commutative. Proof: \Box
```

Exercise: 2 stars, optional (beq\_nat\_refl\_informal) Write an informal proof of the following theorem, using the informal proof of plus\_assoc as a model. Don't just paraphrase the Coq tactics into English!

```
Theorem: true = beq_nat n n for any n. Proof: \Box
```

# Chapter 38

# Library Basics

# 38.1 Basics: Functional Programming in Coq

Definition admit  $\{T: Type\}: T. Admitted.$ 

### 38.2 Introduction

The functional programming style brings programming closer to mathematics: If a procedure or method has no side effects, then pretty much all you need to understand about it is how it maps inputs to outputs – that is, you can think of its behavior as just computing a mathematical function. This is one reason for the word "functional" in "functional programming." This direct connection between programs and simple mathematical objects supports both sound informal reasoning and formal proofs of correctness.

The other sense in which functional programming is "functional" is that it emphasizes the use of functions (or methods) as *first-class* values – i.e., values that can be passed as arguments to other functions, returned as results, stored in data structures, etc. The recognition that functions can be treated as data in this way enables a host of useful idioms, as we will see.

Other common features of functional languages include *algebraic data types* and *pattern matching*, which make it easy to construct and manipulate rich data structures, and sophisticated *polymorphic type systems* that support abstraction and code reuse. Coq shares all of these features.

# 38.3 Enumerated Types

One unusual aspect of Coq is that its set of built-in features is *extremely* small. For example, instead of providing the usual palette of atomic data types (booleans, integers, strings, etc.), Coq offers an extremely powerful mechanism for defining new data types from scratch – so powerful that all these familiar types arise as instances.

Naturally, the Coq distribution comes with an extensive standard library providing definitions of booleans, numbers, and many common data structures like lists and hash tables. But there is nothing magic or primitive about these library definitions: they are ordinary user code.

To see how this works, let's start with a very simple example.

### 38.3.1 Days of the Week

The following declaration tells Coq that we are defining a new set of data values – a type.

```
Inductive day : Type :=
  | monday : day
  | tuesday : day
  | wednesday : day
  | thursday : day
  | friday : day
  | saturday : day
  | sunday : day.
```

The type is called **day**, and its members are monday, tuesday, etc. The second through eighth lines of the definition can be read "monday is a **day**, tuesday is a **day**, etc."

Having defined **day**, we can write functions that operate on days.

```
Definition next_weekday (d:day): day := match d with

| monday \Rightarrow tuesday
| tuesday \Rightarrow wednesday
| wednesday \Rightarrow thursday
| thursday \Rightarrow friday
| friday \Rightarrow monday
| saturday \Rightarrow monday
| sunday \Rightarrow monday
end.
```

One thing to note is that the argument and return types of this function are explicitly declared. Like most functional programming languages, Coq can often work out these types even if they are not given explicitly – i.e., it performs some *type inference* – but we'll always include them to make reading easier.

Having defined a function, we should check that it works on some examples. There are actually three different ways to do this in Coq. First, we can use the command Eval compute to evaluate a compound expression involving next\_weekday.

```
Eval compute in (next_weekday friday).
Eval compute in (next_weekday (next_weekday saturday)).
```

If you have a computer handy, now would be an excellent moment to fire up the Coq interpreter under your favorite IDE – either CoqIde or Proof General – and try this for

yourself. Load this file (Basics.v) from the book's accompanying Coq sources, find the above example, submit it to Coq, and observe the result.

The keyword compute tells Coq precisely how to evaluate the expression we give it. For the moment, compute is the only one we'll need; later on we'll see some alternatives that are sometimes useful.

Second, we can record what we *expect* the result to be in the form of a Coq example:

```
Example test_next_weekday:
```

```
(next_weekday (next_weekday saturday)) = tuesday.
```

This declaration does two things: it makes an assertion (that the second weekday after saturday is tuesday), and it gives the assertion a name that can be used to refer to it later. Having made the assertion, we can also ask Coq to verify it, like this:

```
Proof. simpl. reflexivity. Qed.
```

The details are not important for now (we'll come back to them in a bit), but essentially this can be read as "The assertion we've just made can be proved by observing that both sides of the equality evaluate to the same thing, after some simplification."

Third, we can ask Coq to "extract," from a Definition, a program in some other, more conventional, programming language (OCaml, Scheme, or Haskell) with a high-performance compiler. This facility is very interesting, since it gives us a way to construct *fully certified* programs in mainstream languages. Indeed, this is one of the main uses for which Coq was developed. We'll come back to this topic in later chapters. More information can also be found in the Coq'Art book by Bertot and Casteran, as well as the Coq reference manual.

#### 38.3.2 Booleans

In a similar way, we can define the type **bool** of booleans, with members true and false.

```
Inductive bool : Type :=
  | true : bool
  | false : bool.
```

Although we are rolling our own booleans here for the sake of building up everything from scratch, Coq does, of course, provide a default implementation of the booleans in its standard library, together with a multitude of useful functions and lemmas. (Take a look at Coq.Init.Datatypes in the Coq library documentation if you're interested.) Whenever possible, we'll name our own definitions and theorems so that they exactly coincide with the ones in the standard library.

Functions over booleans can be defined in the same way as above:

```
\begin{array}{l} \texttt{Definition negb} \ (b : \textbf{bool}) : \ \textbf{bool} := \\ \texttt{match} \ b \ \texttt{with} \\ | \ \mathsf{true} \Rightarrow \mathsf{false} \\ | \ \mathsf{false} \Rightarrow \mathsf{true} \\ \texttt{end}. \end{array}
```

```
Definition andb (b1:\mathbf{bool}) (b2:\mathbf{bool}): \mathbf{bool} :=  match b1 with | true \Rightarrow b2 | false \Rightarrow false end. 
Definition orb (b1:\mathbf{bool}) (b2:\mathbf{bool}): \mathbf{bool} :=  match b1 with | true \Rightarrow true | false \Rightarrow b2 end.
```

The last two illustrate the syntax for multi-argument function definitions.

The following four "unit tests" constitute a complete specification – a truth table – for the orb function:

```
Example test_orb1: (orb true false) = true.
Proof. reflexivity. Qed.
Example test_orb2: (orb false false) = false.
Proof. reflexivity. Qed.
Example test_orb3: (orb false true) = true.
Proof. reflexivity. Qed.
Example test_orb4: (orb true true) = true.
Proof. reflexivity. Qed.
```

(Note that we've dropped the simpl in the proofs. It's not actually needed because reflexivity will automatically perform simplification.)

A note on notation: We use square brackets to delimit fragments of Coq code in comments in .v files; this convention, also used by the *coqdoc* documentation tool, keeps them visually separate from the surrounding text. In the html version of the files, these pieces of text appear in a *different font*.

The values Admitted and admit can be used to fill a hole in an incomplete definition or proof. We'll use them in the following exercises. In general, your job in the exercises is to replace admit or Admitted with real definitions or proofs.

Exercise: 1 star (nandb) Complete the definition of the following function, then make sure that the Example assertions below can each be verified by Coq.

This function should return true if either or both of its inputs are false.

```
Definition nandb (b1:bool) (b2:bool) : bool :=
   admit.

Remove "Admitted." and fill in each proof with "Proof. reflexivity. Qed."

Example test_nandb1: (nandb true false) = true.
   Admitted.

Example test_nandb2: (nandb false false) = true.
```

```
Admitted.

Example test_nandb3: (nandb false true) = true.

Admitted.

Example test_nandb4: (nandb true true) = false.

Admitted.
```

Exercise: 1 star (andb3) Do the same for the andb3 function below. This function should return true when all of its inputs are true, and false otherwise.

```
Definition andb3 (b1:bool) (b2:bool) (b3:bool) : bool :=
   admit.

Example test_andb31: (andb3 true true true) = true.
   Admitted.

Example test_andb32: (andb3 false true true) = false.
   Admitted.

Example test_andb33: (andb3 true false true) = false.
   Admitted.

Example test_andb34: (andb3 true true false) = false.
   Admitted.

□
```

### 38.3.3 Function Types

The Check command causes Coq to print the type of an expression. For example, the type of negb true is **bool**.

```
Check true.
Check (negb true).
```

Functions like negb itself are also data values, just like true and false. Their types are called *function types*, and they are written with arrows.

Check negb.

The type of negb, written **bool**  $\rightarrow$  **bool** and pronounced "**bool** arrow **bool**," can be read, "Given an input of type **bool**, this function produces an output of type **bool**." Similarly, the type of andb, written **bool**  $\rightarrow$  **bool**, can be read, "Given two inputs, both of type **bool**, this function produces an output of type **bool**."

### 38.3.4 Numbers

Technical digression: Coq provides a fairly sophisticated module system, to aid in organizing large developments. In this course we won't need most of its features, but one is useful: If we enclose a collection of declarations between Module X and End X markers, then, in the remainder of the file after the End, these definitions will be referred to by names like X.foo

instead of just foo. Here, we use this feature to introduce the definition of the type **nat** in an inner module so that it does not shadow the one from the standard library.

#### Module PLAYGROUND1.

The types we have defined so far are examples of "enumerated types": their definitions explicitly enumerate a finite set of elements. A more interesting way of defining a type is to give a collection of "inductive rules" describing its elements. For example, we can define the natural numbers as follows:

```
\label{eq:condition} \begin{array}{l} \text{Inductive nat}: \ \text{Type} := \\ \mid O: \ \text{nat} \\ \mid S: \ \text{nat} \rightarrow \ \text{nat}. \end{array}
```

The clauses of this definition can be read:

- O is a natural number (note that this is the letter "O," not the numeral "0").
- ullet S is a "constructor" that takes a natural number and yields another one that is, if n is a natural number, then S n is too.

Let's look at this in a little more detail.

Every inductively defined set (day, nat, bool, etc.) is actually a set of *expressions*. The definition of nat says how expressions in the set nat can be constructed:

- the expression O belongs to the set **nat**;
- if n is an expression belonging to the set nat, then S n is also an expression belonging to the set nat; and
- expressions formed in these two ways are the only ones belonging to the set **nat**.

The same rules apply for our definitions of **day** and **bool**. The annotations we used for their constructors are analogous to the one for the O constructor, and indicate that each of those constructors doesn't take any arguments.

These three conditions are the precise force of the Inductive declaration. They imply that the expression O, the expression S O, the expression S O, the expression S O, and so on all belong to the set O, while other expressions like true, and O true false, and O O O0 O1.

We can write simple functions that pattern match on natural numbers just as we did above – for example, the predecessor function:

```
\begin{array}{l} \text{Definition pred } (n: \mathbf{nat}): \mathbf{nat} := \\ \text{match } n \text{ with} \\ \mid \mathsf{O} \Rightarrow \mathsf{O} \\ \mid \mathsf{S} \ n' \Rightarrow n' \\ \text{end.} \end{array}
```

The second branch can be read: "if n has the form S n' for some n', then return n'."

#### End PLAYGROUND1.

```
Definition minustwo (n: \mathbf{nat}): \mathbf{nat} :=  match n with | \ \mathbf{O} \Rightarrow \mathbf{O}  | \ \mathbf{S} \ \mathbf{O} \Rightarrow \mathbf{O}  | \ \mathbf{S} \ (\mathbf{S} \ n') \Rightarrow n'  end.
```

Because natural numbers are such a pervasive form of data, Coq provides a tiny bit of built-in magic for parsing and printing them: ordinary arabic numerals can be used as an alternative to the "unary" notation defined by the constructors S and O. Coq prints numbers in arabic form by default:

```
Check (S (S (S O)))).
Eval simpl in (minustwo 4).
```

The constructor S has the type  $nat \rightarrow nat$ , just like the functions minustwo and pred:

```
Check S.
Check pred.
Check minustwo.
```

These are all things that can be applied to a number to yield a number. However, there is a fundamental difference: functions like pred and minustwo come with *computation rules* – e.g., the definition of pred says that pred 2 can be simplified to 1 – while the definition of S has no such behavior attached. Although it is like a function in the sense that it can be applied to an argument, it does not *do* anything at all!

For most function definitions over numbers, pure pattern matching is not enough: we also need recursion. For example, to check that a number n is even, we may need to recursively check whether n-2 is even. To write such functions, we use the keyword Fixpoint.

```
Fixpoint evenb (n:\mathsf{nat}): \mathsf{bool} := \mathsf{match}\ n \ \mathsf{with} \ | \ \mathsf{O} \Rightarrow \mathsf{true} \ | \ \mathsf{S} \ \mathsf{O} \Rightarrow \mathsf{false} \ | \ \mathsf{S} \ (\mathsf{S} \ n') \Rightarrow \mathsf{evenb} \ n' \ \mathsf{end}.
```

We can define oddb by a similar Fixpoint declaration, but here is a simpler definition that will be a bit easier to work with:

```
Definition oddb (n:nat): bool := negb (evenb n).

Example test_oddb1: (oddb (S O)) = true.

Proof. reflexivity. Qed.

Example test_oddb2: (oddb (S (S (S O))))) = false.

Proof. reflexivity. Qed.
```

Naturally, we can also define multi-argument functions by recursion. (Once again, we use a module to avoid polluting the namespace.)

```
Module PLAYGROUND2.
```

```
Fixpoint plus (n: nat) (m: nat): nat:= match n with | O \Rightarrow m  | S n' \Rightarrow S (plus n' m) end.
```

Adding three to two now gives us five, as we'd expect.

```
Eval simpl in (plus (S(S(SO)))(S(SO))).
```

The simplification that Coq performs to reach this conclusion can be visualized as follows:

As a notational convenience, if two or more arguments have the same type, they can be written together. In the following definition,  $(n \ m : nat)$  means just the same as if we had written (n : nat) (m : nat).

```
Fixpoint mult (n \ m : \mathbf{nat}) : \mathbf{nat} :=  match n with \mid \mathbf{O} \Rightarrow \mathbf{O}  \mid \mathbf{S} \ n' \Rightarrow \mathsf{plus} \ m \ (\mathsf{mult} \ n' \ m)  end.
```

Example test\_mult1: (mult 3 3) = 9. Proof. reflexivity. Qed.

You can match two expressions at once by putting a comma between them:

```
Fixpoint minus (n \ m: nat): nat := match n, m with \mid O, - \Rightarrow O \mid S -, O \Rightarrow n \mid S n', S m' \Rightarrow minus n' m' end.
```

The \_in the first line is a *wildcard pattern*. Writing \_in a pattern is the same as writing some variable that doesn't get used on the right-hand side. This avoids the need to invent a bogus variable name.

End Playground2.

```
Fixpoint exp (base\ power: nat): nat:= match power with | \ O \Rightarrow S \ O  | \ S \ p \Rightarrow mult\ base\ (exp\ base\ p) end.
```

**Exercise:** 1 star (factorial) Recall the standard factorial function:

```
factorial(0) = 1
factorial(n) = n * factorial(n-1) (if n>0)

Translate this into Coq.

Fixpoint factorial (n:nat): nat := admit.

Example test_factorial1: (factorial 3) = 6.

Admitted.

Example test_factorial2: (factorial 5) = (mult 10 12).

Admitted.
```

We can make numerical expressions a little easier to read and write by introducing "notations" for addition, multiplication, and subtraction.

```
Notation "\mathbf{x} + \mathbf{y}" := (plus x y) (at level 50, left associativity) : nat\_scope.

Notation "\mathbf{x} - \mathbf{y}" := (minus x y) (at level 50, left associativity) : nat\_scope.

Notation "\mathbf{x} * \mathbf{y}" := (mult x y) (at level 40, left associativity) : nat\_scope.

Check ((0 + 1) + 1).
```

(The level, associativity, and  $nat\_scope$  annotations control how these notations are treated by Coq's parser. The details are not important, but interested readers can refer to the "More on Notation" subsection in the "Optional Material" section at the end of this chapter.)

Note that these do not change the definitions we've already made: they are simply instructions to the Coq parser to accept x + y in place of plus x y and, conversely, to the Coq pretty-printer to display plus x y as x + y.

When we say that Coq comes with nothing built-in, we really mean it: even equality testing for numbers is a user-defined operation! The beq\_nat function tests natural numbers for equality, yielding a boolean. Note the use of nested matches (we could also have used a simultaneous match, as we did in minus.)

```
Fixpoint beq_nat (n \ m : \mathbf{nat}) : \mathbf{bool} :=  match n with | \ \mathbf{O} \Rightarrow \mathbf{match} \ m with | \ \mathbf{O} \Rightarrow \mathbf{true}  | \ \mathbf{S} \ m' \Rightarrow \mathbf{false}  end | \ \mathbf{S} \ n' \Rightarrow \mathbf{match} \ m with
```

```
\mid \mathbf{O} \Rightarrow \mathsf{false}
\mid \mathbf{S} \ m' \Rightarrow \mathsf{beq\_nat} \ n' \ m'
end
```

end.

Similarly, the ble\_nat function tests natural numbers for less-or-equal, yielding a boolean.

```
Fixpoint ble_nat (n m : nat) : bool :=
  match n with
  | O ⇒ true
  | S n' ⇒
      match m with
      | O ⇒ false
      | S m' ⇒ ble_nat n' m'
      end
  end.

Example test_ble_nat1: (ble_nat 2 2) = true.
Proof. reflexivity. Qed.
Example test_ble_nat2: (ble_nat 2 4) = true.
Proof. reflexivity. Qed.
Example test_ble_nat3: (ble_nat 4 2) = false.
Proof. reflexivity. Qed.
```

Exercise: 2 stars (blt\_nat) The blt\_nat function tests natural numbers for less-than, yielding a boolean. Instead of making up a new Fixpoint for this one, define it in terms of a previously defined function.

Note: If you have trouble with the simpl tactic, try using compute, which is like simpl on steroids. However, there is a simple, elegant solution for which simpl suffices.

```
Definition blt_nat (n m : nat) : bool := admit.

Example test_blt_nat1: (blt_nat 2 2) = false.
   Admitted.

Example test_blt_nat2: (blt_nat 2 4) = true.
   Admitted.

Example test_blt_nat3: (blt_nat 4 2) = false.
   Admitted.
```

# 38.4 Proof by Simplification

Now that we've defined a few datatypes and functions, let's turn to the question of how to state and prove properties of their behavior. Actually, in a sense, we've already started doing

this: each Example in the previous sections makes a precise claim about the behavior of some function on some particular inputs. The proofs of these claims were always the same: use reflexivity to check that both sides of the = simplify to identical values.

(By the way, it will be useful later to know that reflexivity actually does somewhat more than simpl – for example, it tries "unfolding" defined terms, replacing them with their right-hand sides. The reason for this difference is that, when reflexivity succeeds, the whole goal is finished and we don't need to look at whatever expanded expressions reflexivity has found; by contrast, simpl is used in situations where we may have to read and understand the new goal, so we would not want it blindly expanding definitions.)

The same sort of "proof by simplification" can be used to prove more interesting properties as well. For example, the fact that 0 is a "neutral element" for + on the left can be proved just by observing that 0 + n reduces to n no matter what n is, a fact that can be read directly off the definition of plus.

```
Theorem plus_O_n : \forall n : \mathbf{nat}, 0 + n = n. Proof. intros n. reflexivity. Qed.
```

(*Note*: You may notice that the above statement looks different in the original source file and the final html output. In Coq files, we write the  $\forall$  universal quantifier using the "forall" reserved identifier. This gets printed as an upside-down "A", the familiar symbol used in logic.)

The form of this theorem and proof are almost exactly the same as the examples above; there are just a few differences.

First, we've used the keyword keyword Theorem instead of Example. Indeed, the latter difference is purely a matter of style; the keywords Example and Theorem (and a few others, including Lemma, Fact, and Remark) mean exactly the same thing to Coq.

Secondly, we've added the quantifier  $\forall$  n:nat, so that our theorem talks about *all* natural numbers n. In order to prove theorems of this form, we need to to be able to reason by assuming the existence of an arbitrary natural number n. This is achieved in the proof by intros n, which moves the quantifier from the goal to a "context" of current assumptions. In effect, we start the proof by saying "OK, suppose n is some arbitrary number."

The keywords intros, simpl, and reflexivity are examples of *tactics*. A tactic is a command that is used between Proof and Qed to tell Coq how it should check the correctness of some claim we are making. We will see several more tactics in the rest of this lecture, and yet more in future lectures.

Step through these proofs in Coq and notice how the goal and context change.

```
Theorem plus_1_I : \forall n:nat, 1 + n = S n. Proof.

intros n. reflexivity. Qed.

Theorem mult_0_I : \forall n:nat, 0 \times n = 0.

Proof.

intros n. reflexivity. Qed.
```

The -l suffix in the names of these theorems is pronounced "on the left."

# 38.5 Proof by Rewriting

Here is a slightly more interesting theorem:

```
Theorem plus_id_example : \forall n m:nat,

n = m \rightarrow

n + n = m + m.
```

Instead of making a completely universal claim about all numbers n and m, this theorem talks about a more specialized property that only holds when n=m. The arrow symbol is pronounced "implies."

As before, we need to be able to reason by assuming the existence of some numbers n and m. We also need to assume the hypothesis n=m. The intros tactic will serve to move all three of these from the goal into assumptions in the current context.

Since n and m are arbitrary numbers, we can't just use simplification to prove this theorem. Instead, we prove it by observing that, if we are assuming n=m, then we can replace n with m in the goal statement and obtain an equality with the same expression on both sides. The tactic that tells Coq to perform this replacement is called rewrite.

Proof.

```
intros n m. intros H. rewrite \rightarrow H. reflexivity. Qed.
```

The first line of the proof moves the universally quantified variables n and m into the context. The second moves the hypothesis n = m into the context and gives it the (arbitrary) name H. The third tells Coq to rewrite the current goal (n + n = m + m) by replacing the left side of the equality hypothesis H with the right side.

(The arrow symbol in the **rewrite** has nothing to do with implication: it tells Coq to apply the rewrite from left to right. To rewrite from right to left, you can use **rewrite** ←. Try making this change in the above proof and see what difference it makes in Coq's behavior.)

Exercise: 1 star (plus\_id\_exercise) Remove "Admitted." and fill in the proof.

```
Theorem plus_id_exercise : \forall n \ m \ o : nat, n = m \rightarrow m = o \rightarrow n + m = m + o.

Proof.

Admitted.
```

As we've seen in earlier examples, the Admitted command tells Coq that we want to skip trying to prove this theorem and just accept it as a given. This can be useful for developing longer proofs, since we can state subsidiary facts that we believe will be useful for making some larger argument, use Admitted to accept them on faith for the moment, and continue thinking about the larger argument until we are sure it makes sense; then we can go back

and fill in the proofs we skipped. Be careful, though: every time you say *Admitted* (or admit) you are leaving a door open for total nonsense to enter Coq's nice, rigorous, formally checked world!

We can also use the rewrite tactic with a previously proved theorem instead of a hypothesis from the context.

```
Theorem mult_0_plus: \forall n \ m : \mathbf{nat}, (0+n) \times m = n \times m.

Proof.

intros n \ m.

rewrite \rightarrow plus_0_n.

reflexivity. Qed.

Exercise: \mathbf{2} \ \text{stars} \ (\mathbf{mult_S_1}) Theorem mult_S_1: \forall n \ m : \mathbf{nat}, m = \mathbf{S} \ n \rightarrow m \times (1+n) = m \times m.

Proof.

Admitted.
```

# 38.6 Proof by Case Analysis

Of course, not everything can be proved by simple calculation: In general, unknown, hypothetical values (arbitrary numbers, booleans, lists, etc.) can block the calculation. For example, if we try to prove the following fact using the simpl tactic as above, we get stuck.

```
Theorem plus_1_neq_0_firsttry : \forall n : \mathbf{nat}, beq_nat (n+1) 0 = false. Proof. intros n. simpl. Abort.
```

The reason for this is that the definitions of both beq\_nat and + begin by performing a match on their first argument. But here, the first argument to + is the unknown number n and the argument to beq\_nat is the compound expression n + 1; neither can be simplified.

What we need is to be able to consider the possible forms of n separately. If n is O, then we can calculate the final result of beq\_nat (n + 1) 0 and check that it is, indeed, false. And if n = S n' for some n', then, although we don't know exactly what number n + 1 yields, we can calculate that, at least, it will begin with one S, and this is enough to calculate that, again, beq\_nat (n + 1) 0 will yield false.

The tactic that tells Coq to consider, separately, the cases where n=0 and where n=1 is called destruct.

```
Theorem plus_1_neq_0 : \forall n : nat, beq_nat (n + 1) 0 = false.
```

Proof.

```
intros n. destruct n as [\mid n']. reflexivity. qed.
```

The destruct generates two subgoals, which we must then prove, separately, in order to get Coq to accept the theorem as proved. (No special command is needed for moving from one subgoal to the other. When the first subgoal has been proved, it just disappears and we are left with the other "in focus.") In this proof, each of the subgoals is easily proved by a single use of reflexivity.

The annotation "as [|n']" is called an *intro pattern*. It tells Coq what variable names to introduce in each subgoal. In general, what goes between the square brackets is a *list* of lists of names, separated by |. Here, the first component is empty, since the O constructor is nullary (it doesn't carry any data). The second component gives a single name, n, since S is a unary constructor.

The destruct tactic can be used with any inductively defined datatype. For example, we use it here to prove that boolean negation is involutive - i.e., that negation is its own inverse.

```
Theorem negb_involutive : ∀ b : bool,
  negb (negb b) = b.
Proof.
  intros b. destruct b.
    reflexivity.
  reflexivity. Qed.
```

Note that the destruct here has no as clause because none of the subcases of the destruct need to bind any variables, so there is no need to specify any names. (We could also have written as []], or as [].) In fact, we can omit the as clause from any destruct and Coq will fill in variable names automatically. Although this is convenient, it is arguably bad style, since Coq often makes confusing choices of names when left to its own devices.

```
Exercise: 1 star (zero_nbeq_plus_1) Theorem zero_nbeq_plus_1 : \forall n : nat, beq_nat 0 (n + 1) = false.

Proof.

Admitted.
```

### 38.7 More Exercises

Exercise: 2 stars (boolean functions) Use the tactics you have learned so far to prove the following theorem about boolean functions.

```
Theorem identity_fn_applied_twice : \forall (f : \mathbf{bool} \rightarrow \mathbf{bool}),
```

```
(\forall \ (x: \mathbf{bool}), f \ x = x) \rightarrow \\ \forall \ (b: \mathbf{bool}), f \ (f \ b) = b. \\ \mathsf{Proof}. \\ Admitted.
```

Now state and prove a theorem  $negation\_fn\_applied\_twice$  similar to the previous one but where the second hypothesis says that the function f has the property that  $f \times negb \times$ 

Exercise: 2 stars (andb\_eq\_orb) Prove the following theorem. (You may want to first prove a subsidiary lemma or two.)

```
Theorem andb_eq_orb : \forall (b \ c : \mathbf{bool}), (andb b \ c = \mathrm{orb} \ b \ c) <math>\rightarrow b = c.
Proof.

Admitted.
```

**Exercise: 3 stars (binary)** Consider a different, more efficient representation of natural numbers using a binary rather than unary system. That is, instead of saying that each natural number is either zero or the successor of a natural number, we can say that each binary number is either

- zero,
- twice a binary number, or
- one more than twice a binary number.
- (a) First, write an inductive definition of the type *bin* corresponding to this description of binary numbers.

(Hint: Recall that the definition of **nat** from class, Inductive nat: Type := | O: nat | S: nat -> nat. says nothing about what O and S "mean." It just says "O is in the set called **nat**, and if **n** is in the set then so is S n." The interpretation of O as zero and S as successor/plus one comes from the way that we *use* **nat** values, by writing functions to do things with them, proving things about them, and so on. Your definition of *bin* should be correspondingly simple; it is the functions you will write next that will give it mathematical meaning.)

- (b) Next, write an increment function for binary numbers, and a function to convert binary numbers to unary numbers.
- (c) Write some unit tests for your increment and binary-to-unary functions. Notice that incrementing a binary number and then converting it to unary should yield the same result as first converting it to unary and then incrementing.

## 38.8 Optional Material

### 38.8.1 More on Notation

```
Notation "\mathbf{x} + \mathbf{y}" := (plus x y) (at level 50, left associativity) : nat\_scope.

Notation "\mathbf{x} * \mathbf{y}" := (mult x y) (at level 40, left associativity) : nat\_scope.
```

For each notation-symbol in Coq we can specify its precedence level and its associativity. The precedence level n can be specified by the keywords at level n and it is helpful to disambiguate expressions containing different symbols. The associativity is helpful to disambiguate expressions containing more occurrences of the same symbol. For example, the parameters specified above for + and  $\times$  say that the expression 1+2\*3\*4 is a shorthand for the expression (1+((2\*3)\*4)). Coq uses precedence levels from 0 to 100, and left, right, or no associativity.

Each notation-symbol in Coq is also active in a *notation scope*. Coq tries to guess what scope you mean, so when you write  $S(O \times O)$  it guesses  $nat\_scope$ , but when you write the cartesian product (tuple) type **bool**×**bool** it guesses  $type\_scope$ . Occasionally you have to help it out with percent-notation by writing  $(x \times y)\%$ **nat**, and sometimes in Coq's feedback to you it will use %**nat** to indicate what scope a notation is in.

Notation scopes also apply to numeral notation (3,4,5, etc.), so you may sometimes see 0%**nat** which means O, or 0%Z which means the Integer zero.

## 38.8.2 Fixpoints and Structural Recursion

```
Fixpoint plus' (n: \mathbf{nat}) (m: \mathbf{nat}): \mathbf{nat}:= match n with | \mathsf{O} \Rightarrow m  | \mathsf{S} \ n' \Rightarrow \mathsf{S} \ (\mathsf{plus'} \ n' \ m) end.
```

When Coq checks this definition, it notes that plus' is "decreasing on 1st argument." What this means is that we are performing a *structural recursion* over the argument n - i.e., that we make recursive calls only on strictly smaller values of n. This implies that all calls to plus' will eventually terminate. Coq demands that some argument of *every* Fixpoint definition is "decreasing".

This requirement is a fundamental feature of Coq's design: In particular, it guarantees that every function that can be defined in Coq will terminate on all inputs. However, because Coq's "decreasing analysis" is not very sophisticated, it is sometimes necessary to write functions in slightly unnatural ways.

Exercise: 2 stars, optional (decreasing) To get a concrete sense of this, find a way to write a sensible Fixpoint definition (of a simple function on numbers, say) that *does* terminate on all inputs, but that Coq will *not* accept because of this restriction.

# Chapter 39

# Library Preface

### 39.1 Preface

### 39.2 Welcome

This electronic book is a course on *Software Foundations*, the mathematical underpinnings of reliable software. Topics include basic concepts of logic, computer-assisted theorem proving and the Coq proof assistant, functional programming, operational semantics, Hoare logic, and static type systems. The exposition is intended for a broad range of readers, from advanced undergraduates to PhD students and researchers. No specific background in logic or programming languages is assumed, though a degree of mathematical maturity will be helpful.

One novelty of the course is that it is one hundred per cent formalized and machine-checked: the entire text is literally a script for Coq. It is intended to be read alongside an interactive session with Coq. All the details in the text are fully formalized in Coq, and the exercises are designed to be worked using Coq.

The files are organized into a sequence of core chapters, covering about one semester's worth of material and organized into a coherent linear narrative, plus a number of "appendices" covering additional topics. All the core chapters are suitable for both graduate and upper-level undergraduate students.

### 39.3 Overview

Building reliable software is hard. The scale and complexity of modern software systems, the number of people involved in building them, and the range of demands placed on them make it extremely difficult to build software that works as intended, even most of the time. At the same time, the increasing degree to which software is woven into almost every aspect of our society continually amplifies the cost of bugs and insecurities.

Computer science and software engineering have responded to these challenges by developing a whole host of techniques for improving software reliability, ranging from recommendations about managing software projects and structuring programming teams (e.g., extreme programming) to design philosophies for libraries (e.g., model-view-controller, publish-subscribe, etc.) and programming languages (e.g., object-oriented programming, aspect-oriented programming, functional programming), to mathematical techniques for specifying and reasoning about properties of software and tools for helping validate these properties.

The present course is focused on this last set of techniques. The text weaves together five conceptual threads:

- (1) basic tools from *logic* for making and justifying precise claims about programs;
- (2) the use of *proof assistants* to construct rigorous logical arguments;
- (3) the idea of *functional programming*, both as a method of programming and as a bridge between programming and logic;
- (4) formal techniques for reasoning about the properties of specific programs (e.g., that a loop terminates on all inputs, or that a sorting function actually fulfills its specification); and
- (5) the use of *type systems* for establishing well-behavedness guarantees for *all* programs in a given programming language (e.g., the fact that well-typed Java programs cannot be subverted at runtime).

Each of these topics is easily rich enough to fill a whole course in its own right; taking all of them together naturally means that much will be left unsaid. But we hope readers will agree that the themes illuminate and amplify each other in useful ways, and that bringing them together creates a foundation from which it will be easy to dig into any of them more deeply. Some suggestions for supplemental texts can be found in the *Postscript* chapter.

### 39.3.1 Logic

Logic is the field of study whose subject matter is proofs – unassailable arguments for the truth of particular propositions.

Volumes have been written about the central role of logic in computer science. Manna and Waldinger called it "the calculus of computer science," while Halpern et al.'s paper *On the Unusual Effectiveness of Logic in Computer Science* catalogs scores of ways in which logic offers critical tools and insights.

In particular, the fundamental notion of inductive proofs is ubiquitous in all of computer science. You have surely seen them before, in contexts from discrete math to analysis of algorithms, but in this course we will examine them much more deeply than you have probably done so far.

### 39.3.2 Proof Assistants

The flow of ideas between logic and computer science has not gone only one way: CS has made its own contributions to logic. One of these has been the development of tools for constructing proofs of logical propositions. These tools fall into two broad categories:

- Automated theorem provers provide "push-button" operation: you give them a proposition and they return either true, false, or ran out of time. Although their capabilities are limited to fairly specific sorts of reasoning, they have matured enough to be useful now in a huge variety of settings. Examples of such tools include SAT solvers, SMT solvers, and model checkers.
- *Proof assistants* are hybrid tools that try to automate the more routine aspects of building proofs while depending on human guidance for more difficult aspects. Widely used proof assistants include Isabelle, Agda, Twelf, ACL2, PVS, and Coq, among many others.

This course is based around Coq, a proof assistant that has been under development since 1983 at a number of French research labs and universities. Coq provides a rich environment for interactive development of machine-checked formal reasoning. The kernel of the Coq system is a simple proof-checker which guarantees that only correct deduction steps are performed. On top of this kernel, the Coq environment provides high-level facilities for proof development, including powerful tactics for constructing complex proofs semi-automatically, and a large library of common definitions and lemmas.

Coq has been a critical enabler for a huge variety of work across computer science and mathematics.

- As a platform for the modeling of programming languages, it has become a standard tool for researchers who need to describe and reason about complex language definitions. It has been used, for example, to check the security of the JavaCard platform, obtaining the highest level of common criteria certification, and for formal specifications of the x86 and LLVM instruction sets.
- As an environment for the development of formally certified programs, Coq has been used to build CompCert, a fully-verified optimizing compiler for C, for proving the correctness of subtle algorithms involving floating point numbers, and as the basis for Certicrypt, an environment for reasoning about the security of cryptographic algorithms.
- As a realistic environment for experiments with programming with dependent types, it has inspired numerous innovations. For example, the Ynot project at Harvard embeds "relational Hoare reasoning" (an extension of the *Hoare Logic* we will see later in this course) in Coq.
- As a proof assistant for higher-order logic, it has been used to validate a number of important results in mathematics. For example, its ability to include complex computations inside proofs made it possible to develop the first formally verified proof of the 4-color theorem. This proof had previously been controversial among mathematicians because part of it included checking a large number of configurations using a program. In the Coq formalization, everything is checked, including the correctness

of the computational part. More recently, an even more massive effort led to a Coq formalization of the Feit-Thompson Theorem – the first major step in the classification of finite simple groups.

By the way, in case you're wondering about the name, here's what the official Coq web site says: "Some French computer scientists have a tradition of naming their software as animal species: Caml, Elan, Foc or Phox are examples of this tacit convention. In French, "coq" means rooster, and it sounds like the initials of the Calculus of Constructions CoC on which it is based." The rooster is also the national symbol of France, and "Coq" are the first three letters of the name of Thierry Coquand, one of Coq's early developers.

### 39.3.3 Functional Programming

The term functional programming refers both to a collection of programming idioms that can be used in almost any programming language and to a particular family of programming languages that are designed to emphasize these idioms, including Haskell, OCaml, Standard ML, F#, Scala, Scheme, Racket, Common Lisp, Clojure, Erlang, and Coq.

Functional programming has been developed by researchers over many decades – indeed, its roots go back to Church's lambda-calculus, developed in the 1930s before the era of the computer began! But in the past two decades it has enjoyed a surge of interest among industrial engineers and language designers, playing a key role in high-value systems at companies like Jane St. Capital, Microsoft, Facebook, and Ericsson.

The most basic tenet of functional programming is that, as much as possible, computation should be pure: the only effect of running a computation should be to produce a result; the computation should be free from side effects such as I/O, assignments to mutable variables, or redirecting pointers. For example, whereas an imperative sorting function might take a list of numbers and rearrange the pointers to put the list in order, a pure sorting function would take the original list and return a new list containing the same numbers in sorted order.

One significant benefit of this style of programming is that it makes programs easier to understand and reason about. If every operation on a data structure yields a new data structure, leaving the old one intact, then there is no need to worry about where else in the program the structure is being shared, whether a change by one part of the program might break an invariant that another part of the program thinks is being enforced. These considerations are particularly critical in concurrent programs, where any mutable state that is shared between threads is a potential source of pernicious bugs. Indeed, a large part of the recent interest in functional programming in industry is due to its simple behavior in the presence of concurrency.

Another reason for the current excitement about functional programming is related to this one: functional programs are often much easier to parallelize than their imperative counterparts. If running a computation has no effect other than producing a result, then it can be run anywhere. If a data structure is never modified in place, it can be copied freely, across cores or across the network. Indeed, the MapReduce idiom that lies at the heart of massively distributed query processors like Hadoop and is used at Google to index the entire web is an instance of functional programming.

For purposes of this course, functional programming has one other significant attraction: it serves as a bridge between logic and computer science. Indeed, Coq itself can be seen as a combination of a small but extremely expressive functional programming language, together with a set of tools for stating and proving logical assertions. However, when we come to look more closely, we will find that these two sides of Coq are actually aspects of the very same underlying machinery – i.e., proofs are programs.

### 39.3.4 Program Verification

The first third of the book is devoted to developing the conceptual framework of logic and functional programming and to gaining enough fluency with the essentials of Coq to use it for modeling and reasoning about nontrivial artifacts. From this point on, we will increasingly turn our attention to two broad topics of critical importance to the enterprise of building reliable software (and hardware!): techniques for proving specific properties of particular programs and for proving general properties of whole programming languages.

For both of these, the first thing we need is a way of representing programs as mathematical objects (so we can talk about them precisely) and of describing their behavior in terms of mathematical functions or relations. Our tools for these tasks will be abstract syntax and operational semantics, a method of specifying the behavior of programs by writing abstract interpreters. At the beginning, we will work with operational semantics in the so-called "big-step" style, which leads to somewhat simpler and more readable definitions, in those cases where it is applicable. Later on, we will switch to a more detailed "small-step" style, which helps make some useful distinctions between different sorts of "nonterminating" program behaviors and which can be applied to a broader range of language features, including concurrency.

The first programming language we consider in detail is Imp, a tiny toy language capturing the most fundamental features of conventional imperative languages: variables, assignment, conditionals, and loops. We study two different ways of reasoning about the properties of Imp programs.

First, we consider what it means to say that two Imp programs are *equivalent* in the sense that they give the same behaviors for all initial memories. This notion of equivalence then becomes a criterion for judging the correctness of *metaprograms* – programs that manipulate other programs, such as compilers and optimizers. We build a simple optimizer for Imp and prove that it is correct.

Second, we develop a methodology for proving that Imp programs satisfy some formal specification of their behavior. We introduce the notion of *Hoare triples* – Imp programs annotated with pre- and post-conditions describing what should be true about the memory in which they are started and what they promise to make true about the memory in which they terminate – and the reasoning principles of *Hoare Logic*, a "domain-specific logic" specialized for convenient compositional reasoning about imperative programs, with concepts like "loop invariant" built in.

This part of the course will give you a taste of the key ideas and mathematical tools used for a wide variety of real-world software and hardware verification tasks.

### 39.3.5 Type Systems

Our final major topic, covering the last third of the course, is *type systems*, a powerful set of tools for establishing properties of *all* programs in a given language.

Type systems are the best established and most popular example of a highly successful class of formal verification techniques known as *lightweight formal methods*. These are reasoning techniques of modest power – modest enough that automatic checkers can be built into compilers, linkers, or program analyzers and thus be applied even by programmers unfamiliar with the underlying theories. (Other examples of lightweight formal methods include hardware and software model checkers and run-time property monitoring, a collection of techniques that allow a system to detect, dynamically, when one of its components is not behaving according to specification).

In a sense, this topic brings us full circle: the language whose properties we study in this part, called the *simply typed lambda-calculus*, is essentially a simplified model of the core of Coq itself!

### 39.4 Practicalities

### 39.4.1 System Requirements

Cog runs on Windows, Linux, and OS X. You will need:

- A current installation of Coq, available from the Coq home page. Everything should work with patch level of version 8.4.
- An IDE for interacting with Coq. Currently, there are two choices:
  - Proof General is an Emacs-based IDE. It tends to be preferred by users who are already comfortable with Emacs. It requires a separate installation (google "Proof General").
  - CoqIDE is a simpler stand-alone IDE. It is distributed with Coq, but on some platforms compiling it involves installing additional packages for GUI libraries and such.

### 39.4.2 Exercises

Each chapter includes numerous exercises. Each is marked with a "star rating," which can be interpreted as follows:

- One star: easy exercises that underscore points in the text and that, for most readers, should take only a minute or two. Get in the habit of working these as you reach them.
- Two stars: straightforward exercises (five or ten minutes).
- Three stars: exercises requiring a bit of thought (ten minutes to half an hour).
- Four and five stars: more difficult exercises (half an hour and up).

Also, some exercises are marked "advanced", and some are marked "optional." Doing just the non-optional, non-advanced exercises should provide good coverage of the core material. "Advanced" exercises are for readers who want an extra challenge (and, in return, a deeper contact with the material). "Optional" exercises provide a bit of extra practice with key concepts and introduce secondary themes that may be of interest to some readers.

### 39.4.3 Chapter Dependencies

A diagram of the dependencies between chapters and some suggested paths through the material can be found in the file deps.html.

### 39.4.4 Downloading the Coq Files

A tar file containing the full sources for the "release version" of these notes (as a collection of Coq scripts and HTML files) is available here:

http://www.cis.upenn.edu/~bcpierce/sf

If you are using the notes as part of a class, you may be given access to a locally extended version of the files, which you should use instead of the release version.

## 39.5 Note for Instructors

If you intend to use these materials in your own course, you will undoubtedly find things you'd like to change, improve, or add. Your contributions are welcome!

Please send an email to Benjamin Pierce, and we'll set you up with read/write access to our subversion repository and developers' mailing list; in the repository you'll find a README with further instructions.

# 39.6 Translations

Thanks to the efforts of a team of volunteer translators, *Software Foundations* can now be enjoyed in Japanese:
