Chapter 2

Library Preface

2.1 Preface

This electronic book is a one-semester course on *Software Foundations* – the mathematical theory of programming and programming languages – suitable for graduate or upper-level undergraduate students. It develops basic concepts of functional programming, logic, operational semantics, lambda-calculus, and static type systems, using the Coq proof assistant.

The main novelty of the course is that the development is formalized and machine-checked: the text is literally a script for the Coq proof assistant. It is intended to be read hand-in-hand with the accompanying Coq source file in an interactive session with Coq. All the details of the lectures are fully developed in Coq, and the exercises are designed to be worked using Coq.

The files are organized into a sequence of core chapters, covering about one semester's worth of material and organized into a coherent linear narrative, plus several "appendices" covering additional topics.

2.2 Overview

The course weaves together several fundamental themes:

• Logic as the mathematical basis for software engineering:

In particular, inductively defined sets and relations and inductive proofs about them are ubiquitous in all of computer science. The course examines them from many angles.

• Functional programming, an increasingly important part of the software developer's bag of tricks:

- Advanced programming idioms in mainstream software development methodologies are increasingly incorporating ideas from functional programming.
- In particular, using persistent data structures and avoiding mutable state enormously simplifies many concurrent programming tasks.
- Foundations of programming languages (the second part of the course):
 - Notations and techniques for rigorously describing and stress-testing new programming languages and language features. (Designing new programming languages is a surprisingly common activity! Most large software systems include subsystems that are basically programming languages think of regular expressions, command-line formats, preference and configuration files, SQL, Flash, PDF, etc., etc.)
 - A more sophisticated understanding of the everyday tools used to build software...
 what's going on under the hood of your favorite programming language.
- Coq, an industrial-strength proof assistant:
 - Proof assistants are becoming more and more popular in both software and hardware industries. Coq is not the only one out there, but learning one thoroughly will give you a big advantage in coming to grips with another.

2.3 Practicalities

2.3.1 Chapter Dependencies

A diagram of the dependencies between chapters and some suggested paths through the material can be found in the file deps.html.

2.3.2 Required Background

These notes are intended to be accessible to a broad range of readers, from advanced undergraduates to PhD students and researchers. They assume little specific background in programming languages or logic. However, a degree of mathematical maturity will be helpful.

2.4 Coq

Our laboratory for this course is the Coq proof assistant. Coq can be seen as a combination of two things:

- a simple and slightly idiosyncratic (but, in its way, extremely expressive) programming language, together with
- a set of tools for stating *logical assertions* (including assertions about the behavior of programs) and marshalling evidence of their truth.

We will be investigating both aspects in tandem.

2.4.1 System Requirements

Coq runs on Windows and pretty much all flavors of Unix (including Linux and OS X). You will need:

- A current installation of Coq, available from the Coq home page. (Everything is known to compile with 8.3.)
- An IDE for interacting with Coq. Currently, there are two choices:
 - Proof General is an Emacs-based IDE. It tends to be preferred by users who are already comfortable with Emacs. It requires a separate installation (google "Proof General").
 - CoqIDE is a simpler stand-alone IDE. It is distributed with Coq, but on some platforms compiling it involves installing additional packages for GUI libraries and such.

2.4.2 Access to the Coq files

A tar file containing the full sources for the "release version" of these notes (as a collection of Coq scripts and HTML files) is available here:

http://www.cis.upenn.edu/~bcpierce/sf

If you are using the notes as part of a class, you may be given access to a locally extended version of the files, which you should use instead of the release version.

2.5 Exercises

Each chapter of the notes includes numerous exercises. Some are marked "optional", some "recommended." Doing just the non-optional exercises should provide good coverage of the material in approximately six or eight hours of study time (for the longer chapters).

The "star ratings" for the exercises can be interpreted as follows:

- One star: easy exercises that for most readers should take only a minute or two. None of these are explicitly marked "Recommended"; rather, *all* of them should be considered as recommended: readers should be in the habit of working them as they reach them.
- Two stars: straightforward exercises (five or ten minutes).
- Three stars: exercises requiring a bit of thought (fifteen minutes to half an hour).
- Four stars: more difficult exercises (an hour or two).

2.6 Recommended Reading

Some suggestions for supplemental texts can be found in the *Postscript* chapter.

2.7 Translations

Thanks to the efforts of a team of volunteer translators, *Software Foundations* can now be enjoyed in Japanese:

• http://proofcafe.org/sf

2.8 For Instructors

If you intend to use these materials in your own course, you will undoubtedly find things you'd like to change, improve, or add. Your contributions are welcome!

Please send an email to Benjamin Pierce, and we'll set you up with read/write access to our subversion repository and developers' mailing list; in the repository you'll find a README with further instructions.

Chapter 3

Library Basics

3.1 Basics: Functional Programming

3.2 Enumerated Types

In Coq's programming language, almost nothing is built in – not even booleans or numbers! Instead, it provides powerful tools for defining new types of data and functions that process and transform them.

3.2.1 Days of the Week

Let's start with a very simple example. The following declaration tells Coq that we are defining a new set of data values - a "type." The type is called day, and its members are monday, tuesday, etc. The lines of the definition can be read "monday is a day, tuesday is a day, etc."

```
Inductive day : Type :=
    | monday : day
    | tuesday : day
    | wednesday : day
    | friday : day
    | saturday : day
    | sunday : day
    | sunday : day.
    Having defined day, we can write functions that operate on days.

Definition next_weekday (d:day) : day :=
    match d with
    | monday ⇒ tuesday
    | tuesday ⇒ wednesday
    | wednesday ⇒ thursday
```

```
| thursday ⇒ friday
| friday ⇒ monday
| saturday ⇒ monday
| sunday ⇒ monday
end.
```

One thing to note is that the argument and return types of this function are explicitly declared. Like most functional programming languages, Coq can often work out these types even if they are not given explicitly – i.e., it performs some *type inference* – but we'll always include them to make reading easier.

Having defined a function, we should check that it works on some examples. There are actually three different ways to do this in Coq. First, we can use the command Eval simpl to evaluate a compound expression involving next_weekday.

```
Eval simpl in (next_weekday friday).
Eval simpl in (next_weekday (next_weekday saturday)).
```

If you have a computer handy, now would be an excellent moment to fire up the Coq interpreter under your favorite IDE – either CoqIde or Proof General – and try this for yourself. Load this file (Basics.v) from the book's accompanying Coq sources, find the above example, submit it to Coq, and observe the result.

The keyword simpl ("simplify") tells Coq precisely how to evaluate the expression we give it. For the moment, simpl is the only one we'll need; later on we'll see some alternatives that are sometimes useful.

Second, we can record what we *expect* the result to be in the form of a Coq example:

Example test_next_weekday:

```
(next_weekday (next_weekday saturday)) = tuesday.
```

This declaration does two things: it makes an assertion (that the second weekday after saturday is tuesday), and it gives the assertion a name that can be used to refer to it later. Having made the assertion, we can also ask Coq to verify it, like this:

```
Proof. simpl. reflexivity. Qed.
```

The details are not important for now (we'll come back to them in a bit), but essentially this can be read as "The assertion we've just made can be proved by observing that both sides of the equality are the same after simplification."

Third, we can ask Coq to "extract," from a Definition, a program in some other, more conventional, programming language (OCaml, Scheme, or Haskell) with a high-performance compiler. This facility is very interesting, since it gives us a way to construct *fully certified* programs in mainstream languages. Indeed, this is one of the main uses for which Coq was developed. We won't have space to dig further into this topic, but more information can be found in the Coq'Art book by Bertot and CastÃl'ran, as well as the Coq reference manual.

3.2.2 Booleans

In a similar way, we can define the type bool of booleans, with members true and false.

```
Inductive bool : Type :=
  | true : bool
  | false : bool.
```

Although we are rolling our own booleans here for the sake of building up everything from scratch, Coq does, of course, provide a default implementation of the booleans in its standard library, together with a multitude of useful functions and lemmas. (Take a look at *Coq.Init.Datatypes* in the Coq library documentation if you're interested.) Whenever possible, we'll name our own definitions and theorems so that they exactly coincide with the ones in the standard library.

Functions over booleans can be defined in the same way as above:

```
Definition negb (b:\mathbf{bool}):\mathbf{bool}:=
\mathtt{match}\ b with
|\ \mathsf{true} \Rightarrow \mathsf{false}|
|\ \mathsf{false} \Rightarrow \mathsf{true}|
\mathsf{end}.

Definition andb (b1:\mathbf{bool})\ (b2:\mathbf{bool}):\mathbf{bool}:=
\mathtt{match}\ b1 with
|\ \mathsf{true} \Rightarrow b2|
|\ \mathsf{false} \Rightarrow \mathsf{false}|
\mathsf{end}.

Definition orb (b1:\mathbf{bool})\ (b2:\mathbf{bool}):\mathbf{bool}:=
\mathtt{match}\ b1 with
|\ \mathsf{true} \Rightarrow \mathsf{true}|
|\ \mathsf{false} \Rightarrow b2|
|\ \mathsf{end}.
```

The last two illustrate the syntax for multi-argument function definitions.

The following four "unit tests" constitute a complete specification - a truth table - for the orb function:

```
Example test_orb1: (orb true false) = true.

Proof. simpl. reflexivity. Qed.

Example test_orb2: (orb false false) = false.

Proof. simpl. reflexivity. Qed.

Example test_orb3: (orb false true) = true.

Proof. simpl. reflexivity. Qed.

Example test_orb4: (orb true true) = true.

Proof. simpl. reflexivity. Qed.
```

A note on notation: We use square brackets to delimit fragments of Coq code in comments in .v files; this convention, also used by the *coqdoc* documentation tool, keeps them visually separate from the surrounding text. In the html version of the files, these pieces of text appear in a *different font*.

The following bit of Coq hackery defines a magic value called *admit* that can fill a hole in an incomplete definition or proof. We'll use it in the definition of *nandb* in the following exercise. In general, your job in the exercises is to replace *admit* or *Admitted* with real definitions or proofs.

```
Definition admit \{T: Type\}: T. Admitted.
```

Exercise: 1 star (nandb) Complete the definition of the following function, then make sure that the Example assertions below each can be verified by Coq.

This function should return *true* if either or both of its inputs are *false*.

```
Definition nandb (b1:bool) (b2:bool) : bool :=
  admit.
   Remove "Admitted." and fill in each proof with "Proof. simpl. reflexivity. Qed."
Example test_nandb1: (nandb true false) = true.
   Admitted.
Example test_nandb2: (nandb false false) = true.
   Admitted.
Example test_nandb3: (nandb false true) = true.
   Admitted.
Example test_nandb4: (nandb true true) = false.
   Admitted.
   Exercise: 1 star (andb3) Definition andb3 (b1:bool) (b2:bool) (b3:bool): bool:=
Example test_andb31: (andb3 true true true) = true.
   Admitted.
Example test_andb32: (andb3 false true true) = false.
   Admitted.
Example test_andb33: (andb3 true false true) = false.
   Admitted.
Example test_andb34: (andb3 true true false) = false.
   Admitted.
```

3.2.3 Function Types

The Check command causes Coq to print the type of an expression. For example, the type of negb true is bool.

```
Check true.
Check (negb true).
```

Functions like *negb* itself are also data values, just like *true* and *false*. Their types are called *function types*, and they are written with arrows.

Check negb.

The type of negb, written bool o bool and pronounced "bool arrow bool," can be read, "Given an input of type bool, this function produces an output of type bool." Similarly, the type of andb, written bool o bool o bool, can be read, "Given two inputs, both of type bool, this function produces an output of type bool."

3.2.4 Numbers

Technical digression: Coq provides a fairly fancy module system, to aid in organizing large developments. In this course, we won't need most of its features, but one of them is useful: if we enclose a collection of declarations between Module X and End X markers, then, in the remainder of the file after the End, all these definitions will be referred to by names like X.foo instead of just foo. This means that the new definition will not clash with the unqualified name foo later, which would otherwise be an error (a name can only be defined once in a given scope). Here, we use this feature to introduce the definition of the type nat in an inner module so that it does not shadow the one from the standard library.

Module PLAYGROUND1.

The types we have defined so far are examples of "enumerated types": their definitions explicitly enumerate a finite set of elements. A more interesting way of defining a type is to give a collection of "inductive rules" describing its elements. For example, we can define the natural numbers as follows:

```
\label{eq:condition} \begin{array}{l} \text{Inductive nat}: \ \text{Type} := \\ \mid O: \ \text{nat} \\ \mid S: \ \text{nat} \rightarrow \ \text{nat}. \end{array}
```

The clauses of this definition can be read:

- O is a natural number (note that this is the letter "O," not the numeral "0").
- S is a "constructor" that takes a natural number and yields another one that is, if n is a natural number, then S n is too.

Let's look at this in a little more detail.

Every inductively defined set (weekday, nat, bool, etc.) is actually a set of expressions. The definition of nat says how expressions in the set nat can be constructed:

- the expression O belongs to the set nat;
- if n is an expression belonging to the set nat, then S n is also an expression belonging to the set nat; and
- expressions formed in these two ways are the only ones belonging to the set nat.

These three conditions are the precise force of the Inductive declaration. They imply that the expression O, the expression S (S (S (S O)), and so on all belong to the set nat, while other expressions like true, andb true false, and S (S false) do not.

We can write simple functions that pattern match on natural numbers just as we did above – for example, predecessor:

```
\begin{array}{c} \texttt{Definition pred}\ (n: \texttt{nat}): \texttt{nat} := \\ \texttt{match}\ n \ \texttt{with} \\ \mid \texttt{O} \Rightarrow \texttt{O} \\ \mid \texttt{S}\ n' \Rightarrow n' \\ \texttt{end} \end{array}
```

The second branch can be read: "if n has the form S n' for some n', then return n'."

End PLAYGROUND1.

```
Definition minustwo (n: \mathbf{nat}): \mathbf{nat} :=  match n with | \ \mathbf{O} \Rightarrow \mathbf{O}  | \ \mathbf{S} \ \mathbf{O} \Rightarrow \mathbf{O}  | \ \mathbf{S} \ (\mathbf{S} \ n') \Rightarrow n'  end.
```

Because natural numbers are such a pervasive form of data, Coq provides a tiny bit of built-in magic for parsing and printing them: ordinary arabic numerals can be used as an alternative to the "unary" notation defined by the constructors S and O. Coq prints numbers in arabic form by default:

```
Check (S (S (S O)))).
Eval simpl in (minustwo 4).
```

The constructor S has the type $nat \to nat$, just like the functions minustwo and pred:

```
Check S.
Check pred.
Check minustwo.
```

These are all things that can be applied to a number to yield a number. However, there is a fundamental difference: functions like *pred* and *minustwo* come with *computation rules* - e.g., the definition of *pred* says that *pred* n can be simplified to match n with $|O\Rightarrow O|$ |S| |m| and |m| while the definition of |S| has no such behavior attached. Although it is a function in the sense that it can be applied to an argument, it does not *do* anything at all!

For most function definitions over numbers, pure pattern matching is not enough: we also need recursion. For example, to check that a number n is even, we may need to recursively check whether n-2 is even. To write such functions, we use the keyword Fixpoint.

```
Fixpoint evenb (n:nat): bool := match n with | \bigcirc \Rightarrow true
```

```
| S O \Rightarrow false
| S (S n') \Rightarrow evenb n'
end.
```

When Coq checks this definition, it notes that evenb is "decreasing on 1st argument." What this means is that we are performing a $structural\ recursion$ over the argument n – i.e., that we make recursive calls only on strictly smaller values of n. This implies that all calls to evenb will eventually terminate. Coq demands that some argument of eveny Fixpoint definition is decreasing.

We can define oddb by a similar Fixpoint declaration, but here is a simpler definition that will be a bit easier to work with:

```
Definition oddb (n:nat): bool := negb (evenb n).

Example test_oddb1: (oddb (S O)) = true.

Proof. simpl. reflexivity. Qed.

Example test_oddb2: (oddb (S (S (S O))))) = false.

Proof. simpl. reflexivity. Qed.
```

Naturally, we can also define multi-argument functions by recursion. (Once again, we use a module to avoid polluting the namespace.)

Module PLAYGROUND2.

```
Fixpoint plus (n : nat) (m : nat) : nat := match n with
\mid O \Rightarrow m
\mid S \ n' \Rightarrow S \ (plus \ n' \ m)
end.
```

Adding three to two now gives us five, as we'd expect.

```
Eval simpl in (plus (S(S(SO)))(S(SO))).
```

The simplification that Coq performs to reach this conclusion can be visualized as follows:

As a notational convenience, if two or more arguments have the same type, they can be written together. In the following definition, $(n \ m : nat)$ means just the same as if we had written (n : nat) (m : nat).

```
Fixpoint mult (n \ m : \mathbf{nat}) : \mathbf{nat} :=  match n with | \ \mathbf{O} \Rightarrow \mathbf{O}  | \ \mathbf{S} \ n' \Rightarrow \mathsf{plus} \ m \ (\mathsf{mult} \ n' \ m)  end.
```

You can match two expressions at once by putting a comma between them:

```
Fixpoint minus (n m:nat) : nat := match n, m with
```

```
\begin{array}{l} \mid \mathsf{O} \;,\; - \Rightarrow \mathsf{O} \\ \mid \mathsf{S} \; - \;,\; \mathsf{O} \Rightarrow n \\ \mid \mathsf{S} \; n',\; \mathsf{S} \; m' \Rightarrow \mathsf{minus} \; n' \; m' \\ \mathsf{end}. \end{array}
```

The _in the first line is a *wildcard pattern*. Writing _in a pattern is the same as writing some variable that doesn't get used on the right-hand side. This avoids the need to invent a bogus variable name.

```
End PLAYGROUND2.
```

```
Fixpoint exp (base power: nat): nat:=

match power with

| O \Rightarrow S O
| S p \Rightarrow mult base (exp base p)
end.

Example test_mult1: (mult 3 3) = 9.

Proof. simpl. reflexivity. Qed.
```

Exercise: 1 star (factorial) Recall the standard factorial function:

```
factorial(0) = 1

factorial(n) = n * factorial(n-1) (if n>0)
```

Translate this into Coq.

```
Fixpoint factorial (n:nat): nat := admit.
```

```
Example test_factorial1: (factorial 3) = 6. Admitted.
```

```
Example test_factorial2: (factorial 5) = (mult 10 12).
```

Admitted.

We can make numerical expressions a little easier to read and write by introducing "notations" for addition, multiplication, and subtraction.

```
Notation "\mathbf{x} + \mathbf{y}" := (plus x y) (at level 50, left associativity) : nat\_scope.

Notation "\mathbf{x} - \mathbf{y}" := (minus x y) (at level 50, left associativity) : nat\_scope.

Notation "\mathbf{x} * \mathbf{y}" := (mult x y) (at level 40, left associativity) : nat\_scope.

Check ((0 + 1) + 1).
```

Note that these do not change the definitions we've already made: they are simply instructions to the Coq parser to accept x + y in place of plus x y and, conversely, to the Coq pretty-printer to display plus x y as x + y.

Each notation-symbol in Coq is active in a *notation scope*. Coq tries to guess what scope you mean, so when you write $S(O \times O)$ it guesses nat_scope , but when you write the cartesian product (tuple) type $bool \times bool$ it guesses $type_scope$. Occasionally you have to help it out with percent-notation by writing $(x \times y)\% nat$, and sometimes in Coq's feedback to you it will use % nat to indicate what scope a notation is in.

Notation scopes also apply to numeral notation (3,4,5, etc.), so you may sometimes see 0%nat which means O, or 0%Z which means the Integer zero.

When we say that Coq comes with nothing built-in, we really mean it: even equality testing for numbers is a user-defined operation! The beq_nat function tests natural numbers for equality, yielding a boolean. Note the use of nested matches (we could also have used a simultaneous match, as we did in minus.)

```
Fixpoint beq_nat (n \ m : nat) : bool := match \ n \ with
| \ O \Rightarrow match \ m \ with
| \ O \Rightarrow true
| \ S \ m' \Rightarrow false
end
| \ S \ n' \Rightarrow match \ m \ with
| \ O \Rightarrow false
| \ S \ m' \Rightarrow beq_nat \ n' \ m'
end
end.
```

Similarly, the ble_nat function tests natural numbers for less-or-equal, yielding a boolean.

```
Fixpoint ble_nat (n m : nat) : bool :=
  match n with
  | O ⇒ true
  | S n' ⇒
       match m with
       | O ⇒ false
       | S m' ⇒ ble_nat n' m'
       end
  end.

Example test_ble_nat1: (ble_nat 2 2) = true.
Proof. simpl. reflexivity. Qed.
Example test_ble_nat2: (ble_nat 2 4) = true.
Proof. simpl. reflexivity. Qed.
Example test_ble_nat3: (ble_nat 4 2) = false.
```

Proof. simpl. reflexivity. Qed.

Exercise: 2 stars (blt_nat) The blt_nat function tests natural numbers for less-than, yielding a boolean. Instead of making up a new Fixpoint for this one, define it in terms of a previously defined function.

Note: If you have trouble with the simpl tactic, try using compute, which is like simpl on steroids. However, there is a simple, elegant solution for which simpl suffices.

```
Definition blt_nat (n \ m : nat) : bool := admit.

Example test_blt_nat1: (blt_nat 2 2) = false. Admitted.

Example test_blt_nat2: (blt_nat 2 4) = true. Admitted.

Example test_blt_nat3: (blt_nat 4 2) = false. Admitted.

\Box
```

3.3 Proof By Simplification

Now that we've defined a few datatypes and functions, let's turn to the question of how to state and prove properties of their behavior. Actually, in a sense, we've already started doing this: each Example in the previous sections makes a precise claim about the behavior of some function on some particular inputs. The proofs of these claims were always the same: use the function's definition to simplify the expressions on both sides of the = and notice that they become identical.

The same sort of "proof by simplification" can be used to prove more interesting properties as well. For example, the fact that 0 is a "neutral element" for + on the left can be proved just by observing that 0 + n reduces to n no matter what n is, since the definition of + is recursive in its first argument.

```
Theorem plus_O_n : \forall n:nat, 0 + n = n.
Proof.
simpl. reflexivity. Qed.
```

The reflexivity command implicitly simplifies both sides of the equality before testing to see if they are the same, so we can shorten the proof a little. (It will be useful later to know that reflexivity actually does somwhat more than simpl – for example, it tries "unfolding" defined terms, replacing them with their right-hand sides. The reason for this difference is that, when reflexivity succeeds, the whole goal is finished and we don't need to look at whatever expanded expressions reflexivity has found; by contrast, simpl is used in situations where we may have to read and understand the new goal, so we would not want it blindly expanding definitions.)

```
Theorem plus_O_n': \forall n:nat, 0 + n = n.
Proof.
reflexivity. Qed.
```

The form of this theorem and proof are almost exactly the same as the examples above: the only differences are that we've added the quantifier $\forall n:nat$ and that we've used the keyword Theorem instead of Example. Indeed, the latter difference is purely a matter of style; the keywords Example and Theorem (and a few others, including Lemma, Fact, and Remark) mean exactly the same thing to Coq.

The keywords simpl and reflexivity are examples of *tactics*. A tactic is a command that is used between Proof and Qed to tell Coq how it should check the correctness of some claim we are making. We will see several more tactics in the rest of this lecture, and yet more in future lectures.

Exercise: 1 star, optional (simpl_plus) What will Coq print in response to this query?

What about this one?

Explain the difference. \square

3.4 The intros Tactic

Aside from unit tests, which apply functions to particular arguments, most of the properties we will be interested in proving about programs will begin with some quantifiers (e.g., "for all numbers n, ...") and/or hypothesis ("assuming m=n, ..."). In such situations, we will need to be able to reason by assuming the hypothesis – i.e., we start by saying "OK, suppose n is some arbitrary number," or "OK, suppose m=n."

The intros tactic permits us to do this by moving one or more quantifiers or hypotheses from the goal to a "context" of current assumptions.

For example, here is a slightly different proof of the same theorem.

```
Theorem plus_O_n'' : ∀ n:nat, 0 + n = n.
Proof.
  intros n. reflexivity. Qed.
  Step through this proof in Coq and notice how the goal and context change.
Theorem plus_1_l : ∀ n:nat, 1 + n = S n.
Proof.
  intros n. reflexivity. Qed.
Theorem mult_O_l : ∀ n:nat, 0 × n = 0.
Proof.
  intros n. reflexivity. Qed.
```

The -l suffix in the names of these theorems is pronounced "on the left."

3.5 Proof by Rewriting

Here is a slightly more interesting theorem:

```
Theorem plus_id_example : \forall n m:nat,

n = m \rightarrow

n + n = m + m.
```

Instead of making a completely universal claim about all numbers n and m, this theorem talks about a more specialized property that only holds when n=m. The arrow symbol is pronounced "implies."

Since n and m are arbitrary numbers, we can't just use simplification to prove this theorem. Instead, we prove it by observing that, if we are assuming n = m, then we can replace n with m in the goal statement and obtain an equality with the same expression on both sides. The tactic that tells Coq to perform this replacement is called **rewrite**.

Proof.

```
intros n m. intros H. rewrite \rightarrow H. reflexivity. Qed.
```

The first line of the proof moves the universally quantified variables n and m into the context. The second moves the hypothesis n=m into the context and gives it the name H. The third tells Coq to rewrite the current goal (n+n=m+m) by replacing the left side of the equality hypothesis H with the right side.

(The arrow symbol in the rewrite has nothing to do with implication: it tells Coq to apply the rewrite from left to right. To rewrite from right to left, you can use rewrite ←. Try making this change in the above proof and see what difference it makes in Coq's behavior.)

Exercise: 1 star (plus_id_exercise) Remove "Admitted." and fill in the proof.

```
Theorem plus_id_exercise : \forall n \ m \ o : nat, n = m \rightarrow m = o \rightarrow n + m = m + o.

Proof.

Admitted.
```

The Admitted command tells Coq that we want to give up trying to prove this theorem and just accept it as a given. This can be useful for developing longer proofs, since we can state subsidiary facts that we believe will be useful for making some larger argument, use Admitted to accept them on faith for the moment, and continue thinking about the larger argument until we are sure it makes sense; then we can go back and fill in the proofs we skipped. Be careful, though: every time you say admit or Admitted you are leaving a door open for total nonsense to enter Coq's nice, rigorous, formally checked world!

We can also use the **rewrite** tactic with a previously proved theorem instead of a hypothesis from the context.

```
Theorem mult_0_plus : \forall n \ m : nat,

(0 + n) \times m = n \times m.
```

```
Proof.

intros n m.

rewrite \rightarrow plus_O_n.

reflexivity. Qed.

Exercise: 2 stars, recommended (mult_1_plus) Theorem mult_1_plus: \forall n \ m: nat, (1+n) \times m = m + (n \times m).

Proof.

Admitted.
```

3.6 Case Analysis

Of course, not everything can be proved by simple calculation: In general, unknown, hypothetical values (arbitrary numbers, booleans, lists, etc.) can show up in the "head position" of functions that we want to reason about, blocking simplification. For example, if we try to prove the following fact using the simpl tactic as above, we get stuck.

```
Theorem plus_1_neq_0_firsttry : \forall n : \mathbf{nat}, beq_nat (n+1) 0 = false.

Proof.

intros n. simpl. Admitted.
```

The reason for this is that the definitions of both beq_nat and + begin by performing a match on their first argument. But here, the first argument to + is the unknown number n and the argument to beq_nat is the compound expression n+1; neither can be simplified.

What we need is to be able to consider the possible forms of n separately. If n is O, then we can calculate the final result of beq_nat (n+1) 0 and check that it is, indeed, false. And if n = S n' for some n', then, although we don't know exactly what number n+1 yields, we can calculate that, at least, it will begin with one S, and this is enough to calculate that, again, beq_nat (n+1) 0 will yield false.

The tactic that tells Coq to consider, separately, the cases where n = O and where n = S n' is called destruct.

```
Theorem plus_1_neq_0 : \forall n : nat, beq_nat (n+1) 0 = false. Proof. intros n. destruct n as [\mid n']. reflexivity. qed.
```

The destruct generates two subgoals, which we must then prove, separately, in order to get Coq to accept the theorem as proved. (No special command is needed for moving from one subgoal to the other. When the first subgoal has been proved, it just disappears and we

are left with the other "in focus.") In this proof, each of the subgoals is easily proved by a single use of reflexivity.

The annotation "as [|n']" is called an "intro pattern." It tells Coq what variable names to introduce in each subgoal. In general, what goes between the square brackets is a *list* of lists of names, separated by |. Here, the first component is empty, since the O constructor is nullary (it doesn't carry any data). The second component gives a single name, n, since S is a unary constructor.

The destruct tactic can be used with any inductively defined datatype. For example, we use it here to prove that boolean negation is involutive - i.e., that negation is its own inverse.

```
Theorem negb_involutive : ∀ b : bool,
  negb (negb b) = b.
Proof.
  intros b. destruct b.
  reflexivity.
  reflexivity. Qed.
```

Note that the destruct here has no as clause because none of the subcases of the destruct need to bind any variables, so there is no need to specify any names. (We could also have written "as [|]", or "as []".) In fact, we can omit the as clause from any destruct and Coq will fill in variable names automatically. Although this is convenient, it is arguably bad style, since Coq often makes confusing choices of names when left to its own devices.

```
Exercise: 1 star (zero_nbeq_plus_1) Theorem zero_nbeq_plus_1 : \forall n : nat, beq_nat 0 (n + 1) = false.

Proof.

Admitted.
```

3.7 Naming Cases

The fact that there is no explicit command for moving from one branch of a case analysis to the next can make proof scripts rather hard to read. In larger proofs, with nested case analyses, it can even become hard to stay oriented when you're sitting with Coq and stepping through the proof. (Imagine trying to remember that the first five subgoals belong to the inner case analysis and the remaining seven cases are what remains of the outer one...) Disciplined use of indentation and comments can help, but a better way is to use the *Case* tactic.

Case is not built into Coq: we need to define it ourselves. There is no need to understand how it works – just skip over the definition to the example that follows. It uses some facilities of Coq that we have not discussed – the string library (just for the concrete syntax of quoted

strings) and the Ltac command, which allows us to declare custom tactics. Kudos to Aaron Bohannon for this nice hack!

```
Require String. Open Scope string_scope.
Ltac move\_to\_top \ x :=
  match reverse goal with
  \mid H: \_ \vdash \_ \Rightarrow \mathsf{try} \; \mathsf{move} \; x \; \mathsf{after} \; H
  end.
Tactic Notation "assert_eq" ident(x) constr(v) :=
  let H := fresh in
  assert (x = v) as H by reflexivity;
  clear H.
Tactic Notation "Case_aux" ident(x) constr(name) :=
  first
    set (x := name); move\_to\_top x
  | assert_eq x name; move_to_top x
  fail 1 "because we are working on a different case" ].
Tactic Notation "Case" constr(name) := Case\_aux Case name.
Tactic Notation "SCase" constr(name) := Case\_aux\ SCase\ name.
Tactic Notation "SSCase" constr(name) := Case\_aux SSCase name.
Tactic Notation "SSSCase" constr(name) := Case\_aux SSSCase name.
Tactic Notation "SSSSCase" constr(name) := Case\_aux SSSSCase name.
Tactic Notation "SSSSSCase" constr(name) := Case\_aux SSSSSCase name.
Tactic Notation "SSSSSSCase" constr(name) := Case\_aux SSSSSSCase name.
Tactic Notation "SSSSSSCase" constr(name) := Case\_aux SSSSSSCase name.
```

Here's an example of how Case is used. Step through the following proof and observe how the context changes.

```
Theorem andb_true_elim1 : \forall \ b \ c : bool, andb b \ c = true \rightarrow b = true.

Proof.
intros b \ c \ H.
destruct b.
Case \ "b = true".
reflexivity.
Case \ "b = false".
rewrite \leftarrow H. reflexivity. Qed.
```

Case does something very trivial: It simply adds a string that we choose (tagged with the identifier "Case") to the context for the current goal. When subgoals are generated, this string is carried over into their contexts. When the last of these subgoals is finally proved and the next top-level goal (a sibling of the current one) becomes active, this string will no longer appear in the context and we will be able to see that the case where we introduced it

is complete. Also, as a sanity check, if we try to execute a new *Case* tactic while the string left by the previous one is still in the context, we get a nice clear error message.

For nested case analyses (i.e., when we want to use a destruct to solve a goal that has itself been generated by a destruct), there is an *SCase* ("subcase") tactic.

Exercise: 2 stars (andb_true_elim2) Prove andb_true_elim2, marking cases (and subcases) when you use destruct.

```
Theorem andb_true_elim2 : \forall \ b \ c : bool, andb b \ c = true \rightarrow c = true. Proof. Admitted.
```

There are no hard and fast rules for how proofs should be formatted in Coq – in particular, where lines should be broken and how sections of the proof should be indented to indicate their nested structure. However, if the places where multiple subgoals are generated are marked with explicit *Case* tactics placed at the beginning of lines, then the proof will be readable almost no matter what choices are made about other aspects of layout.

This is a good place to mention one other piece of (possibly obvious) advice about line lengths. Beginning Coq users sometimes tend to the extremes, either writing each tactic on its own line or entire proofs on one line. Good style lies somewhere in the middle. In particular, one reasonable convention is to limit yourself to 80-character lines. Lines longer than this are hard to read and can be inconvenient to display and print. Many editors have features that help enforce this.

3.8 Induction

We proved above that 0 is a neutral element for + on the left using a simple partial evaluation argument. The fact that it is also a neutral element on the right...

```
Theorem plus_0_r_firsttry : \forall n:nat,
 n + 0 = n.
```

... cannot be proved in the same simple way. Just applying reflexivity doesn't work: the n in n+0 is an arbitrary unknown number, so the match in the definition of + can't be simplified. And reasoning by cases using destruct n doesn't get us much further: the branch of the case analysis where we assume n=0 goes through, but in the branch where n=S n' for some n' we get stuck in exactly the same way. We could use destruct n' to get one step further, but since n can be arbitrarily large, if we try to keep on going this way we'll never be done.

```
Proof.
intros n.
simpl. Admitted.
```

Case analysis gets us a little further, but not all the way:

```
Theorem plus_0_r_secondtry: \forall n:nat, n + 0 = n.

Proof.

intros n. destruct n as [\mid n'].

Case \text{ "}n = 0\text{"}.

reflexivity. Case \text{ "}n = S \text{ n'}".

simpl. Admitted.
```

To prove such facts – indeed, to prove most interesting facts about numbers, lists, and other inductively defined sets – we need a more powerful reasoning principle: *induction*.

Recall (from high school) the principle of induction over natural numbers: If P(n) is some proposition involving a natural number n and we want to show that P holds for all numbers n, we can reason like this:

- show that P(O) holds;
- show that, for any n', if P(n') holds, then so does P(S n');
- conclude that P(n) holds for all n.

In Coq, the steps are the same but the order is backwards: we begin with the goal of proving P(n) for all n and break it down (by applying the induction tactic) into two separate subgoals: first showing P(O) and then showing $P(n') \to P(S n')$. Here's how this works for the theorem we are trying to prove at the moment:

```
Theorem plus_0_r: \forall n:nat, n + 0 = n.

Proof.

intros n. induction n as [\mid n'].

Case \text{"} n = 0 \text{". reflexivity.}

Case \text{"} n = S \text{ n'". simpl. rewrite} \rightarrow IHn'. \text{ reflexivity.} Qed.
```

Like destruct, the induction tactic takes an as... clause that specifies the names of the variables to be introduced in the subgoals. In the first branch, n is replaced by 0 and the goal becomes 0 + 0 = 0, which follows by simplification. In the second, n is replaced by S n' and the assumption n' + 0 = n' is added to the context (with the name IHn', i.e., the Induction Hypothesis for n'). The goal in this case becomes (S n') + 0 = S n', which simplifies to S(n' + 0) = S n', which in turn follows from the induction hypothesis.

```
Theorem minus_diag : \forall n, minus n n = 0.

Proof.

intros n. induction n as [\mid n'].

Case \text{ "} n = 0 \text{ ".}

simpl. reflexivity.

Case \text{ "} n = S \text{ n'".}

simpl. rewrite \rightarrow IHn'. reflexivity. Qed.
```

```
Exercise: 2 stars, recommended (basic_induction) Theorem mult_0_r: \forall n:nat,
  n \times 0 = 0.
Proof.
   Admitted.
Theorem plus_n_Sm : \forall n m : nat,
  S(n + m) = n + (S m).
Proof.
   Admitted.
Theorem plus_comm : \forall n m : nat,
  n + m = m + n.
Proof.
   Admitted.
Fixpoint double (n:nat) :=
  match n with
  \mid 0 \Rightarrow 0
  | S n' \Rightarrow S (S (double n'))
  end.
Exercise: 2 stars (double_plus) Lemma double_plus: \forall n, double n = n + n.
Proof.
   Admitted.
```

Exercise: 1 star (destruct_induction) Briefly explain the difference between the tactics destruct and induction.

3.9 Formal vs. Informal Proof

"Informal proofs are algorithms; formal proofs are code."

The question of what, exactly, constitutes a "proof" of a mathematical claim has challenged philosophers for millenia. A rough and ready definition, though, could be this: a proof of a mathematical proposition P is a written (or spoken) text that instills in the reader or hearer the certainty that P is true. That is, a proof is an act of communication.

Now, acts of communication may involve different sorts of readers. On one hand, the "reader" can be a program like Coq, in which case the "belief" that is instilled is a simple mechanical check that P can be derived from a certain set of formal logical rules, and the proof is a recipe that guides the program in performing this check. Such recipes are formal proofs.

Alternatively, the reader can be a human being, in which case the proof will be written in English or some other natural language, thus necessarily informal. Here, the criteria for success are less clearly specified. A "good" proof is one that makes the reader believe P. But the same proof may be read by many different readers, some of whom may be convinced by a particular way of phrasing the argument, while others may not be. One reader may be particularly pedantic, inexperienced, or just plain thick-headed; the only way to convince them will be to make the argument in painstaking detail. But another reader, more familiar in the area, may find all this detail so overwhelming that they lose the overall thread. All they want is to be told the main ideas, because it is easier to fill in the details for themselves. Ultimately, there is no universal standard, because there is no single way of writing an informal proof that is guaranteed to convince every conceivable reader. In practice, however, mathematicians have developed a rich set of conventions and idioms for writing about complex mathematical objects that, within a certain community, make communication fairly reliable. The conventions of this stylized form of communication give a fairly clear standard for judging proofs good or bad.

Because we are using Coq in this course, we will be working heavily with formal proofs. But this doesn't mean we can ignore the informal ones! Formal proofs are useful in many ways, but they are *not* very efficient ways of communicating ideas between human beings.

For example, here is a proof that addition is associative:

```
Theorem plus_assoc' : \forall n \ m \ p : \mathbf{nat}, n + (m + p) = (n + m) + p.

Proof. intros n \ m \ p. induction n as [| \ n']. reflexivity. simpl. rewrite \rightarrow \mathit{IHn'}. reflexivity. Qed.
```

Coq is perfectly happy with this as a proof. For a human, however, it is difficult to make much sense of it. If you're used to Coq you can probably step through the tactics one after the other in your mind and imagine the state of the context and goal stack at each point, but if the proof were even a little bit more complicated this would be next to impossible. Instead, a mathematician mighty write it like this:

- Theorem: For any n, m and p, n + (m + p) = (n + m) + p. Proof: By induction on n.
 - First, suppose n = 0. We must show 0 + (m + p) = (0 + m) + p. This follows directly from the definition of +.
 - Next, suppose n = S n', where n' + (m + p) = (n' + m) + p. We must show (S n') + (m + p) = ((S n') + m) + p. By the definition of +, this follows from S (n' + (m + p)) = S ((n' + m) + p), which is immediate from the induction hypothesis. □

The overall form of the proof is basically similar. This is no accident, of course: Coq has been designed so that its induction tactic generates the same sub-goals, in the same order, as the bullet points that a mathematician would write. But there are significant differences

of detail: the formal proof is much more explicit in some ways (e.g., the use of reflexivity) but much less explicit in others; in particular, the "proof state" at any given point in the Coq proof is completely implicit, whereas the informal proof reminds the reader several times where things stand.

Here is a formal proof that shows the structure more clearly:

```
Theorem plus_assoc : \forall n \ m \ p : nat,
  n + (m + p) = (n + m) + p.
Proof.
  intros n m p. induction n as [ | n' ].
  Case "n = 0".
    reflexivity.
  Case "n = S n".
    simpl. rewrite \rightarrow IHn'. reflexivity. Qed.
Exercise: 2 stars (plus_comm_informal) Translate your solution for plus_comm into
an informal proof.
   Theorem: Addition is commutative.
   Proof: \square
Exercise: 2 stars, optional (beq_nat_refl_informal) Write an informal proof of the
following theorem, using the informal proof of plus_assoc as a model. Don't just paraphrase
the Coq tactics into English!
   Theorem: true = beq\_nat \ n \ n for any n.
   Proof: \square
Exercise: 1 star, optional (beq_nat_refl) Theorem beq_nat_refl: \forall n : nat,
  true = beq_nat n n.
Proof.
   Admitted.
```

3.10 Proofs Within Proofs

In Coq, as in informal mathematics, large proofs are very often broken into a sequence of theorems, with later proofs referring to earlier theorems. Occasionally, however, a proof will need some miscellaneous fact that is too trivial (and of too little general interest) to bother giving it its own top-level name. In such cases, it is convenient to be able to simply state and prove the needed "sub-theorem" right at the point where it is used. The assert tactic allows us to do this. For example, our earlier proof of the $mult_-\theta_-plus$ theorem referred to a previous theorem named $plus_-\theta_-n$. We can also use assert to state and prove $plus_-\theta_-n$ in-line:

```
Theorem mult_0_plus': \forall n \ m: nat, (0+n) \times m = n \times m.

Proof.

intros n \ m.

assert (H: 0+n=n).

Case "Proof of assertion". reflexivity. rewrite \rightarrow H.

reflexivity. Qed.
```

The assert tactic introduces two sub-goals. The first is the assertion itself; by prefixing it with H: we name the assertion H. (Note that we could also name the assertion with as just as we did above with destruct and induction, i.e., assert (0 + n = n) as H. Also note that we mark the proof of this assertion with a Case, both for readability and so that, when using Coq interactively, we can see when we're finished proving the assertion by observing when the "Proof of assertion" string disappears from the context.) The second goal is the same as the one at the point where we invoke assert, except that, in the context, we have the assumption H that 0 + n = n. That is, assert generates one subgoal where we must prove the asserted fact and a second subgoal where we can use the asserted fact to make progress on whatever we were trying to prove in the first place.

Actually, assert will turn out to be handy in many sorts of situations. For example, suppose we want to prove that (n + m) + (p + q) = (m + n) + (p + q). The only difference between the two sides of the = is that the arguments m and n to the first inner + are swapped, so it seems we should be able to use the commutativity of addition $(plus_comm)$ to rewrite one into the other. However, the rewrite tactic is a little stupid about where it applies the rewrite. There are three uses of + here, and it turns out that doing rewrite $\rightarrow plus_comm$ will affect only the outer one.

```
Theorem plus_rearrange_firsttry: \forall n \ m \ p \ q: nat, (n+m)+(p+q)=(m+n)+(p+q). Proof. intros n \ m \ p \ q. rewrite \rightarrow plus\_comm. Admitted.
```

To get $plus_comm$ to apply at the point where we want it, we can introduce a local lemma stating that n + m = m + n (for the particular m and n that we are talking about here), prove this lemma using $plus_comm$, and then use this lemma to do the desired rewrite.

```
Theorem plus_rearrange : \forall n \ m \ p \ q : nat, (n+m)+(p+q)=(m+n)+(p+q). Proof.

intros n \ m \ p \ q.

assert (H\colon n+m=m+n).

Case "Proof of assertion".

rewrite \rightarrow plus\_comm. reflexivity.
```

```
rewrite \rightarrow H. reflexivity. Qed.
```

Exercise: 4 stars, recommended (mult_comm) Use assert to help prove this theorem. You shouldn't need to use induction.

```
Theorem plus_swap : \forall n \ m \ p : nat,
 n + (m + p) = m + (n + p).
Proof.
Admitted.
```

Now prove commutativity of multiplication. (You will probably need to define and prove a separate subsidiary theorem to be used in the proof of this one.) You may find that plus_swap comes in handy.

3.11 More Exercises

Exercise: 3 stars, optional (more_exercises) Take a piece of paper. For each of the following theorems, first *think* about whether (a) it can be proved using only simplification and rewriting, (b) it also requires case analysis (destruct), or (c) it also requires induction. Write down your prediction. Then fill in the proof. (There is no need to turn in your piece of paper; this is just to encourage you to reflect before hacking!)

```
Theorem ble_nat_refl : \forall n:nat, true = ble_nat n n.

Proof.

Admitted.

Theorem zero_nbeq_S : \forall n:nat, beq_nat 0 (S n) = false.

Exercise: 2 stars, optional (plus_swap') The replace tactic allows you to specify a particular subterm to rewrite and what you want it rewritten to. More precisely, replace (t) with (u) replaces (all copies of) expression t in the goal by expression u, and generates t = u as an additional subgoal. This is often useful when a plain rewrite acts on the wrong part of the goal.

Use the replace tactic to do a proof of $plus_swap$ ', just like $plus_swap$ but without needing assert (n + m = m + n).

Theorem plus_swap': $\forall n \ m \ p : nat$,

```
n + (m + p) = m + (n + p).
Proof.
   Admitted.
   Exercise: 3 stars, optional Theorem bool_fn_applied_thrice:
  \forall (f : \mathsf{bool} \to \mathsf{bool}) (b : \mathsf{bool}),

         symmetry.
          apply Heaftrue.
       SSCase "f true = false".
          symmetry.
          apply Heaffalse.
     SCase "f false = false".
       rewrite \leftarrow Heaffalse.
       symmetry.
       apply Heaffalse.
```

Qed.

Exercise: 4 stars, recommended (binary) Consider a different, more efficient representation of natural numbers using a binary rather than unary system. That is, instead of saying that each natural number is either zero or the successor of a natural number, we can say that each binary number is either

- zero,
- twice a binary number, or
- one more than twice a binary number.
- (a) First, write an inductive definition of the type *bin* corresponding to this description of binary numbers.

(Hint: recall that the definition of nat from class, Inductive nat: Type := |O:nat|S:nat->nat. says nothing about what O and S "mean". It just says "O is a nat (whatever that is), and if n is a nat then so is S n". The interpretation of O as zero and S as successor/plus one comes from the way that we use nat values, by writing functions to do things with them, proving things about them, and so on. Your definition of bin should be correspondingly simple; it is the functions you will write next that will give it mathematical meaning.)

- (b) Next, write an increment function for binary numbers, and a function to convert binary numbers to unary numbers.
- (c) Finally, prove that your increment and binary-to-unary functions commute: that is, incrementing a binary number and then converting it to unary yields the same result as first converting it to unary and then incrementing.

Exercise: 5 stars (binary_inverse) This exercise is a continuation of the previous exercise about binary numbers. You will need your definitions and theorems from the previous exercise to complete this one.

- (a) First, write a function to convert natural numbers to binary numbers. Then prove that starting with any natural number, converting to binary, then converting back yields the same natural number you started with.
- (b) You might naturally think that we should also prove the opposite direction: that starting with a binary number, converting to a natural, and then back to binary yields the same number we started with. However, it is not true! Explain what the problem is.
- (c) Define a function *normalize* from binary numbers to binary numbers such that for any binary number b, converting to a natural and then back to binary yields (*normalize b*). Prove it.

Exercise: 2 stars, optional (decreasing) The requirement that some argument to each function be "decreasing" is a fundamental feature of Coq's design: In particular, it guarantees that every function that can be defined in Coq will terminate on all inputs. However, because Coq's "decreasing analysis" is not very sophisticated, it is sometimes necessary to write functions in slightly unnatural ways.

To get a concrete sense of this, find a way to write a sensible Fixpoint definition (of a simple function on numbers, say) that *does* terminate on all inputs, but that Coq will *not* accept because of this restriction.

Chapter 4

Library Lists

4.1 Lists: Working with Structured Data

The next line imports all of our definitions from the previous chapter.

Require Export Basics.

For it to work, you need to use *coqc* to compile *Basics.v* into *Basics.vo*. (This is like making a .class file from a .java file, or a .o file from a .c file.)

Here are two ways to compile your code:

• CoqIDE:

Open Basics.v. In the "Compile" menu, click on "Compile Buffer".

• Command line:

Run coqc Basics.v

In this file, we again use the Module feature to wrap all of the definitions for pairs and lists of numbers in a module so that, later, we can reuse the same names for improved (generic) versions of the same operations.

Module NATLIST.

4.2 Pairs of Numbers

In an Inductive type definition, each constructor can take any number of parameters – none (as with true and O), one (as with S), or more than one, as in this definition:

```
\label{eq:inductive natprod} \begin{split} \text{Inductive natprod}: & \texttt{Type} := \\ & \texttt{pair}: & \textbf{nat} \rightarrow \textbf{nat} \rightarrow \textbf{natprod}. \end{split}
```

This declaration can be read: "There is just one way to construct a pair of numbers: by applying the constructor pair to two arguments of type nat."

We can construct an element of *natprod* like this:

```
Eval simpl in (pair 35).
```

Here are two simple function definitions for extracting the first and second components of a pair. (The definitions also illustrate how to do pattern matching on two-argument constructors.)

```
Definition fst (p: \mathbf{natprod}): \mathbf{nat} :=  match p with | pair x \ y \Rightarrow x end. Definition snd (p: \mathbf{natprod}): \mathbf{nat} :=  match p with | pair x \ y \Rightarrow y end. Eval simpl in (fst (pair 3 \ 5)).
```

Since pairs are used quite a bit, it is nice to be able to write them with the standard mathematical notation (x,y) instead of pair x y. We can tell Coq to allow this with a Notation declaration.

```
Notation "(x, y)" := (pair x y).
```

The new notation can be used both in expressions and in pattern matches (indeed, we've seen it already in the previous chapter – this notation is provided as part of the standard library):

```
Eval simpl in (fst (3,5)).

Definition fst' (p: \mathsf{natprod}) : \mathsf{nat} := \mathsf{match} \ p \ \mathsf{with} 
|\ (x,y) \Rightarrow x 
\mathsf{end}.

Definition \mathsf{snd}' (p: \mathsf{natprod}) : \mathsf{nat} := \mathsf{match} \ p \ \mathsf{with} 
|\ (x,y) \Rightarrow y 
\mathsf{end}.

Definition \mathsf{swap\_pair} \ (p: \mathsf{natprod}) : \mathsf{natprod} := \mathsf{match} \ p \ \mathsf{with} 
|\ (x,y) \Rightarrow (y,x) 
\mathsf{end}
```

Let's try and prove a few simple facts about pairs. If we state the lemmas in a particular (and slightly peculiar) way, we can prove them with just reflexivity (and its built-in simplification):

```
Theorem surjective_pairing': \forall (n \ m : nat), (n,m) = (fst (n,m), snd (n,m)).
```

```
Proof.
```

```
reflexivity. Qed.
```

But reflexivity is not enough if we state the lemma in a more natural way:

```
Theorem surjective_pairing_stuck : \forall (p : natprod), p = (fst p, snd p).

Proof.
simpl. Admitted.
```

We have to expose the structure of p so that simpl can perform the pattern match in fst and snd. We can do this with destruct.

Notice that, unlike for *nats*, **destruct** doesn't generate an extra subgoal here. That's because *natprods* can only be constructed in one way.

```
Theorem surjective_pairing : \forall (p : natprod), p = (fst p, snd p).

Proof.

intros p. destruct p as (n,m). simpl. reflexivity. Qed.
```

Notice that Coq allows us to use the notation we introduced for pairs in the "as..." pattern that tells it what variables to bind.

```
Exercise: 1 star (snd_fst_is_swap) Theorem snd_fst_is_swap : \forall (p : natprod), (snd p, fst p) = swap_pair p.

Proof.

Admitted.
```

```
Exercise: 1 star, optional (fst_swap_is_snd) Theorem fst_swap_is_snd : \forall (p : nat-prod), fst (swap_pair p) = snd p.

Proof.

Admitted.
```

4.3 Lists of Numbers

Generalizing the definition of pairs a little, we can describe the type of *lists* of numbers like this: "A list is either the empty list or else a pair of a number and another list."

```
Inductive natlist : Type :=
  | nil : natlist
  | cons : nat → natlist → natlist.
  For example, here is a three-element list:
```

```
Definition mylist := cons 1 (cons 2 (cons 3 nil)).
```

As with pairs, it is more convenient to write lists in familiar programming notation. The following two declarations allow us to use :: as an infix *cons* operator and square brackets as an "outfix" notation for constructing lists.

```
Notation "x :: l" := (cons x l) (at level 60, right associativity). Notation "[]" := nil.

Notation "[x, ..., y]" := (cons x ... (cons y nil) ..).
```

It is not necessary to fully understand these declarations, but in case you are interested, here is roughly what's going on.

The right associativity annotation tells Coq how to parenthesize expressions involving several uses of :: so that, for example, the next three declarations mean exactly the same thing:

```
Definition mylist1 := 1 :: (2 :: (3 :: nil)).
Definition mylist2 := 1 :: 2 :: 3 :: nil.
Definition mylist3 := [1,2,3].
```

The at level 60 part tells Coq how to parenthesize expressions that involve both :: and some other infix operator. For example, since we defined + as infix notation for the *plus* function at level 50, Notation "x + y" := (plus x y) (at level 50, left associativity). The + operator will bind tighter than ::, so 1 + 2 :: [3] will be parsed, as we'd expect, as (1 + 2) :: [3] rather than 1 + (2 :: [3]).

(By the way, it's worth noting in passing that expressions like "1 + 2 :: [3]" can be a little confusing when you read them in a .v file. The inner brackets, around 3, indicate a list, but the outer brackets are there to instruct the "coqdoc" tool that the bracketed part should be displayed as Coq code rather than running text. These brackets don't appear in the generated HTML.)

The second and third Notation declarations above introduce the standard square-bracket notation for lists; the right-hand side of the third one illustrates Coq's syntax for declaring n-ary notations and translating them to nested sequences of binary constructors.

A number of functions are useful for manipulating lists. For example, the **repeat** function takes a number n and a count and returns a list of length count where every element is n.

```
Fixpoint repeat (n\ count: nat): natlist:= match count with | \ O \Rightarrow nil \ | \ S\ count' \Rightarrow n:: (repeat\ n\ count') end.

The length function calculates the length of a list.

Fixpoint length (l:natlist): nat:= match l with |\ nil \Rightarrow O \ |\ h:: t \Rightarrow S\ (length\ t)
```

end.

The app ("append") function concatenates two lists.

```
Fixpoint app (l1\ l2: \mathbf{natlist}): \mathbf{natlist}:= match l1 with |\ \mathsf{nil} \Rightarrow l2 |\ h::\ t \Rightarrow h::\ (\mathsf{app}\ t\ l2) end.
```

Actually, *app* will be used a lot in some parts of what follows, so it is convenient to have an infix operator for it.

```
Notation "x ++ y" := (app x y) (right associativity, at level 60). Example test_app1: [1,2,3] ++ [4,5] = [1,2,3,4,5]. Proof. reflexivity. Qed. Example test_app2: nil ++ [4,5] = [4,5]. Proof. reflexivity. Qed. Example test_app3: [1,2,3] ++ nil = [1,2,3]. Proof. reflexivity. Qed.
```

Here are two smaller examples of programming with lists. The *hd* function returns the first element (the "head") of the list, while *tail* returns everything but the first element. Of course, the empty list has no first element, so we must pass a default value to be returned in that case.

```
Definition hd (default:nat) (l:natlist) : nat :=
  match l with
  | \text{ nil} \Rightarrow default
  |h::t\Rightarrow h
  end.
Definition tail (l:natlist): natlist:=
  match l with
   nil \Rightarrow nil
  |h::t\Rightarrow t
  end.
Example test_hd1: hd 0 [1,2,3] = 1.
Proof. reflexivity. Qed.
Example test_hd2: hd 0 = 0.
Proof. reflexivity. Qed.
Example test_tail: tail [1,2,3] = [2,3].
Proof. reflexivity. Qed.
```

Exercise: 2 stars, recommended (list_funs) Complete the definitions of nonzeros, oddmembers and counteddmembers below.

```
Fixpoint nonzeros (l:natlist) : natlist :=
  admit.
Example test_nonzeros: nonzeros [0,1,0,2,3,0,0] = [1,2,3].
   Admitted.
Fixpoint oddmembers (l:natlist) : natlist :=
Example test_oddmembers: oddmembers [0,1,0,2,3,0,0] = [1,3].
   Admitted.
Fixpoint countoddmembers (l:natlist) : nat :=
  admit.
Example test_countoddmembers1: countoddmembers [1,0,3,1,4,5] = 4.
   Admitted.
Example test_countoddmembers2: countoddmembers [0,2,4] = 0.
   Admitted.
Example test_countoddmembers3: countoddmembers nil = 0.
   Admitted.
```

Exercise: 3 stars, recommended (alternate) Complete the definition of alternate, which "zips up" two lists into one, alternating between elements taken from the first list and elements from the second. See the tests below for more specific examples.

Note: one natural and elegant way of writing *alternate* will fail to satisfy Coq's requirement that all Fixpoint definitions be "obviously terminating." If you find yourself in this rut, look for a slightly more verbose solution that considers elements of both lists at the same time. (One possible solution requires defining a new kind of pairs, but this is not the only way.)

```
Fixpoint alternate (l1\ l2: natlist): natlist:= admit.

Example test_alternate1: alternate [1,2,3] [4,5,6] = [1,4,2,5,3,6]. Admitted.

Example test_alternate2: alternate [1] [4,5,6] = [1,4,5,6]. Admitted.

Example test_alternate3: alternate [1,2,3] [4] = [1,4,2,3]. Admitted.

Example test_alternate4: alternate [] [20,30] = [20,30]. Admitted.

\square
```

4.3.1 Bags via Lists

A bag (or multiset) is like a set, but each element can appear multiple times instead of just once. One reasonable implementation of bags is to represent a bag of numbers as a list.

```
Definition bag := natlist.
```

Exercise: 3 stars, recommended (bag_functions) Complete the following definitions for the functions *count*, *sum*, *add*, and *member* for bags.

```
Fixpoint count (v:nat) (s:bag) : nat :=
   admit.

All these proofs can be done just by reflexivity.
Example test_count1: count 1 [1,2,3,1,4,1] = 3.
   Admitted.
Example test_count2: count 6 [1,2,3,1,4,1] = 0.
   Admitted.
```

Multiset sum is similar to set union: sum a b contains all the elements of a and of b. (Mathematicians usually define union on multisets a little bit differently, which is why we don't use that name for this operation.) For sum we're giving you a header that does not give explicit names to the arguments. Moreover, it uses the keyword Definition instead of Fixpoint, so even if you had names for the arguments, you wouldn't be able to process them recursively. The point of stating the question this way is to encourage you to think about whether sum can be implemented in another way – perhaps by using functions that have already been defined.

```
Definition sum : bag \rightarrow bag \rightarrow bag :=
  admit.
Example test_sum1: count 1 (sum [1,2,3] [1,4,1]) = 3.
   Admitted.
Definition add (v:nat) (s:bag) : bag :=
  admit.
Example test_add1: count 1 (add 1 [1,4,1]) = 3.
   Admitted.
Example test_add2: count 5 (add 1 [1,4,1]) = 0.
   Admitted.
Definition member (v:nat) (s:bag) : bool :=
  admit.
Example test_member1: member 1 [1,4,1] = true.
   Admitted.
Example test_member2: member 2[1,4,1] = false.
   Admitted.
```

Exercise: 3 stars, optional (bag_more_functions) Here are some more bag functions for you to practice with.

```
Fixpoint remove_one (v:nat) (s:bag) : bag :=
  admit.
Example test_remove_one1: count 5 (remove_one 5 [2,1,5,4,1]) = 0.
   Admitted.
Example test_remove_one2: count 5 (remove_one 5 [2,1,4,1]) = 0.
   Admitted.
Example test_remove_one3: count 4 (remove_one 5 [2,1,4,5,1,4]) = 2.
   Admitted.
Example test_remove_one4:
  count 5 (remove_one 5 [2,1,5,4,5,1,4]) = 1.
   Admitted.
Fixpoint remove_all (v:nat) (s:bag) : bag :=
  admit.
Example test_remove_all1: count 5 (remove_all 5 [2,1,5,4,1]) = 0.
   Admitted.
Example test_remove_all2: count 5 (remove_all 5 [2,1,4,1]) = 0.
   Admitted.
Example test_remove_all3: count 4 (remove_all 5 [2,1,4,5,1,4]) = 2.
   Admitted.
Example test_remove_all4: count 5 (remove_all 5 [2,1,5,4,5,1,4,5,1,4]) = 0.
   Admitted.
Fixpoint subset (s1:bag) (s2:bag) : bool :=
  admit.
Example test_subset1: subset [1,2] [2,1,4,1] = true.
   Admitted.
Example test_subset2: subset [1,2,2] [2,1,4,1] = false.
   Admitted.
```

Exercise: 3 stars, recommended (bag_theorem) Write down an interesting theorem about bags involving the functions *count* and *add*, and prove it. Note that, since this problem is somewhat open-ended, it's possible that you may come up with a theorem which is true, but whose proof requires techniques you haven't learned yet. Feel free to ask for help if you get stuck!

4.4 Reasoning About Lists

Just as with numbers, simple facts about list-processing functions can sometimes be proved entirely by simplification. For example, the simplification performed by reflexivity is enough for this theorem...

```
Theorem nil_app : \forall l:natlist,

[] ++ l = l.

Proof.

reflexivity. Qed.
```

... because the [] is substituted into the match position in the definition of app, allowing the match itself to be simplified.

Also, as with numbers, it is sometimes helpful to perform case analysis on the possible shapes (empty or non-empty) of an unknown list.

```
Theorem tl_length_pred : \forall l:natlist, pred (length l) = length (tail l).

Proof.

intros l. destruct l as [| \ n \ l'].

Case \ "l = nil".

reflexivity.

Case \ "l = cons \ n \ l'".

reflexivity. Qed.
```

Here, the nil case works because we've chosen to define tail nil = nil. Notice that the as annotation on the destruct tactic here introduces two names, n and l', corresponding to the fact that the cons constructor for lists takes two arguments (the head and tail of the list it is constructing).

Usually, though, interesting theorems about lists require induction for their proofs.

4.4.1 Micro-Sermon

Simply reading example proofs will not get you very far! It is very important to work through the details of each one, using Coq and thinking about what each step of the proof achieves. Otherwise it is more or less guaranteed that the exercises will make no sense.

4.4.2 Induction on Lists

Proofs by induction over datatypes like *natlist* are perhaps a little less familiar than standard natural number induction, but the basic idea is equally simple. Each **Inductive** declaration defines a set of data values that can be built up from the declared constructors: a boolean can be either *true* or *false*; a number can be either *O* or *S* applied to a number; a list can be either *nil* or *cons* applied to a number and a list.

Moreover, applications of the declared constructors to one another are the *only* possible shapes that elements of an inductively defined set can have, and this fact directly gives rise

to a way of reasoning about inductively defined sets: a number is either O or else it is S applied to some smaller number; a list is either nil or else it is cons applied to some number and some smaller list; etc. So, if we have in mind some proposition P that mentions a list l and we want to argue that P holds for all lists, we can reason as follows:

- First, show that P is true of l when l is nil.
- Then show that P is true of l when l is $cons \ n \ l'$ for some number n and some smaller list l', assuming that P is true for l'.

Since larger lists can only be built up from smaller ones, eventually reaching nil, these two things together establish the truth of P for all lists l. Here's a concrete example:

```
Theorem app_ass: \forall \ l1 \ l2 \ l3 : \mathbf{natlist}, (l1 ++ l2) ++ l3 = l1 ++ (l2 ++ l3). Proof.

intros l1 \ l2 \ l3. induction l1 \ as \ [| \ n \ l1']. Case \ "l1 = nil". reflexivity.

Case \ "l1 = \cos n \ l1'". simpl. rewrite \rightarrow \mathit{IHl1'}. reflexivity. Qed.
```

Again, this Coq proof is not especially illuminating as a static written document – it is easy to see what's going on if you are reading the proof in an interactive Coq session and you can see the current goal and context at each point, but this state is not visible in the written-down parts of the Coq proof. So a natural-language proof – one written for human readers – will need to include more explicit signposts; in particular, it will help the reader stay oriented if we remind them exactly what the induction hypothesis is in the second case.

Theorem: For all lists l1, l2, and l3, (l1 ++ l2) ++ l3 = l1 ++ (l2 ++ l3). Proof: By induction on l1.

- First, suppose l1 = []. We must show $(\Box ++ 12) ++ 13 = \Box ++ (12 ++ 13)$, which follows directly from the definition of ++.
- Next, suppose l1 = n:: l1', with (l1' ++ l2) ++ l3 = l1' ++ (l2 ++ l3) (the induction hypothesis). We must show ((n:: l1') ++ l2) ++ l3 = (n:: l1') ++ (l2 ++ l3).

]] By the definition of ++, this follows from n :: ((l1'++l2)++l3) = n :: (l1'++(l2++l3)), which is immediate from the induction hypothesis. \square Here is an exercise to be worked together in class:

```
Theorem app_length : \forall l1 l2 : natlist, length (l1 ++ l2) = (length l1) + (length l2). Proof.

intros l1 l2. induction l1 as [| n l1']. Case "l1 = nil".
```

```
reflexivity. 
 Case "l1 = cons". 
 simpl. rewrite \rightarrow IHl1'. reflexivity. Qed.
```

For a slightly more involved example of an inductive proof over lists, suppose we define a "cons on the right" function *snoc* like this...

```
Fixpoint snoc (l:natlist) (v:nat) : natlist := match l with |\operatorname{nil} \Rightarrow [v]| |h::t\Rightarrow h:: (snoc t v) end.

... and use it to define a list-reversing function rev like this: Fixpoint rev (l:natlist) : natlist := match l with |\operatorname{nil} \Rightarrow \operatorname{nil}| |h::t\Rightarrow \operatorname{snoc}(\operatorname{rev} t)|h end.

Example test_rev1: rev [1,2,3] = [3,2,1]. Proof. reflexivity. Qed. Example test_rev2: rev nil = nil. Proof. reflexivity. Qed.
```

Now let's prove some more list theorems using our newly defined *snoc* and *rev*. For something a little more challenging than the inductive proofs we've seen so far, let's prove that reversing a list does not change its length. Our first attempt at this proof gets stuck in the successor case...

```
Theorem rev_length_firsttry : \forall l : natlist, length (rev l) = length l.

Proof.

intros l. induction l as [|n|l'].

Case "l = []".

reflexivity.

Case "l = n :: l'".

simpl.

rewrite \leftarrow IHl'.

Admitted.
```

So let's take the equation about *snoc* that would have enabled us to make progress and prove it as a separate lemma.

```
Case "l = nil".
    reflexivity.
  Case "l = \cos n' l'".
     simpl. rewrite \rightarrow IHl'. reflexivity. Qed.
   Now we can complete the original proof.
Theorem rev_length : \forall l : natlist,
  length (rev l) = length l.
Proof.
  intros l. induction l as [|n|l'].
  Case "l = nil".
    reflexivity.
  Case "l = cons".
    simpl. rewrite \rightarrow length_snoc.
    rewrite \rightarrow IHl'. reflexivity. Qed.
   For comparison, here are informal proofs of these two theorems:
   Theorem: For all numbers n and lists l, length (snoc l n) = S (length l).
   Proof: By induction on l.
```

- First, suppose l = []. We must show length (snoc \square n) = S (length \square), which follows directly from the definitions of *length* and *snoc*.
- Next, suppose l = n'::l', with length (snoc l' n) = S (length l'). We must show length (snoc (n' :: l') n) = S (length (n' :: l')). By the definitions of *length* and *snoc*, this follows from S (length (snoc l' n)) = S (S (length l')),

]] which is immediate from the induction hypothesis. \square Theorem: For all lists l, length $(rev \ l) = length \ l$. Proof: By induction on l.

- First, suppose l = []. We must show length (rev \square) = length \square , which follows directly from the definitions of *length* and *rev*.
- Next, suppose l = n::l', with length (rev l') = length l'. We must show length (rev (n :: l')) = length (n :: l'). By the definition of rev, this follows from length (snoc (rev l') n) = S (length l') which, by the previous lemma, is the same as S (length (rev l')) = S (length l'). This is immediate from the induction hypothesis. \square

Obviously, the style of these proofs is rather longwinded and pedantic. After the first few, we might find it easier to follow proofs that give a little less detail overall (since we can easily work them out in our own minds or on scratch paper if necessary) and just highlight the non-obvious steps. In this more compressed style, the above proof might look more like this:

Theorem: For all lists l, length (rev l) = length l.

Proof: First, observe that length (snoc l n) = S (length l) for any l. This follows by a straightforward induction on l. The main property now follows by another straightforward induction on l, using the observation together with the induction hypothesis in the case where l = n'::l'. \square

Which style is preferable in a given situation depends on the sophistication of the expected audience and on how similar the proof at hand is to ones that the audience will already be familiar with. The more pedantic style is a good default for present purposes.

4.4.3 SearchAbout

We've seen that proofs can make use of other theorems we've already proved, using rewrite, and later we will see other ways of reusing previous theorems. But in order to refer to a theorem, we need to know its name, and remembering the names of all the theorems we might ever want to use can become quite difficult! It is often hard even to remember what theorems have been proven, much less what they are named.

Coq's SearchAbout command is quite helpful with this. Typing SearchAbout foo will cause Coq to display a list of all theorems involving foo. For example, try uncommenting the following to see a list of theorems that we have proved about rev:

Keep SearchAbout in mind as you do the following exercises and throughout the rest of the course; it can save you a lot of time!

Also, if you are using ProofGeneral, you can run SearchAbout with C-c C-a C-a. Pasting its response into your buffer can be accomplished with C-c C-;.

4.4.4 List Exercises, Part 1

Exercise: 3 stars, recommended (list_exercises) More practice with lists.

```
Theorem app_nil_end : \forall l : natlist, l ++ [] = l.

Proof. Admitted.

Theorem rev_involutive : \forall l : natlist, rev (rev l) = l.

Proof. Admitted.
```

There is a short solution to the next exercise. If you find yourself getting tangled up, step back and try to look for a simpler way.

```
Theorem app_ass4 : \forall \ l1 \ l2 \ l3 \ l4 : natlist, l1 ++ (l2 ++ (l3 ++ l4)) = ((l1 ++ l2) ++ l3) ++ l4. Proof. Admitted.

Theorem snoc_append : \forall \ (l:natlist) \ (n:nat),
```

```
snoc l n = l ++ [n].

Proof.

Admitted.

Theorem distr_rev : \forall l1 l2 : natlist,
rev (l1 ++ l2) = (rev l2) ++ (rev l1).

Proof.

Admitted.

An exercise about your implementation of nonzeros:

Lemma nonzeros_length : \forall l1 l2 : natlist,
nonzeros (l1 ++ l2) = (nonzeros l1) ++ (nonzeros l2).

Proof.

Admitted.
```

4.4.5 List Exercises, Part 2

Exercise: 2 stars, recommended (list_design) Design exercise:

- Write down a non-trivial theorem involving cons (::), snoc, and append (++).
- Prove it.

Exercise: 2 stars, optional (bag_proofs) If you did the optional exercise about bags above, here are a couple of little theorems to prove about your definitions.

```
Theorem count_member_nonzero : \forall (s : bag), ble_nat 1 (count 1 (1 :: s)) = true.

Proof.

Admitted.

The following lemma about ble_nat might help you in the next proof.

Theorem ble_n_Sn : \forall n, ble_nat n (S n) = true.

Proof.

intros n. induction n as [| n'].

Case "0".

simpl. reflexivity.

Case "S n'".

simpl. rewrite IHn'. reflexivity. Qed.

Theorem remove_decreases_count: \forall (s : bag).
```

ble_nat (count 0 (remove_one 0 s)) (count 0 s) = true.

```
Proof. Admitted.
```

Exercise: 3 stars, optional (bag_count_sum) Write down an interesting theorem about bags involving the functions *count* and *sum*, and prove it.

Exercise: 4 stars, optional (rev_injective) Prove that the *rev* function is injective, that is,

```
for
all (l1 l2 : natlist), rev l1 = rev l2 -> l1 = l2. There is a hard way and an easy way to solve this exercise.
 \Box
```

4.5 Options

Here is another type definition that is often useful in day-to-day programming:

```
Inductive natoption : Type := | Some : nat \rightarrow natoption | None : natoption.
```

One use of *natoption* is as a way of returning "error codes" from functions. For example, suppose we want to write a function that returns the *n*th element of some list. If we give it type $nat \rightarrow nat$ is then we'll have to return some number when the list is too short!

```
Fixpoint index_bad (n:\mathbf{nat}) (l:\mathbf{natlist}) : \mathbf{nat} :=  match l with | \ \mathsf{nil} \Rightarrow 42  | \ a :: \ l' \Rightarrow \mathsf{match} \ \mathsf{beq\_nat} \ n \ \mathsf{O} \ \mathsf{with}  | \ \mathsf{true} \Rightarrow a  | \ \mathsf{false} \Rightarrow \mathsf{index\_bad} \ (\mathsf{pred} \ n) \ l'  end end.
```

On the other hand, if we give it type $nat \to natlist \to natoption$, then we can return None when the list is too short and $Some\ a$ when the list has enough members and a appears at position n.

```
Fixpoint index (n:\mathbf{nat}) (l:\mathbf{natlist}): \mathbf{natoption} :=  \mathbf{match}\ l with |\ \mathsf{nil} \Rightarrow \mathsf{None}\ |\ a :: \ l' \Rightarrow \mathsf{match}\ \mathsf{beq\_nat}\ n \ \mathsf{O} with |\ \mathsf{true} \Rightarrow \mathsf{Some}\ a |\ \mathsf{false} \Rightarrow \mathsf{index}\ (\mathsf{pred}\ n)\ l'
```

end

```
end.
```

```
Example test_index1: index 0 [4,5,6,7] = Some 4. Proof. reflexivity. Qed.

Example test_index2: index 3 [4,5,6,7] = Some 7. Proof. reflexivity. Qed.

Example test_index3: index 10 [4,5,6,7] = None.

Proof. reflexivity. Qed.
```

This example is also an opportunity to introduce one more small feature of Coq's programming language: conditional expressions...

```
Fixpoint index' (n:\mathbf{nat}) (l:\mathbf{natlist}): \mathbf{natoption} :=  \mathbf{match}\ l with |\ \mathsf{nil} \Rightarrow \mathsf{None}\ |\ a :: \ l' \Rightarrow \mathsf{if}\ \mathsf{beq\_nat}\ n O then Some a else index' (\mathsf{pred}\ n)\ l' end.
```

Coq's conditionals are exactly like those found in any other language, with one small generalization. Since the boolean type is not built in, Coq actually allows conditional expressions over *any* inductively defined type with exactly two constructors. The guard is considered true if it evaluates to the first constructor in the Inductive definition and false if it evaluates to the second.

The function below pulls the nat out of a natoption, returning a supplied default in the None case.

```
\begin{array}{l} {\rm Definition\ option\_elim\ }(d:{\bf nat})\ (o:{\bf natoption}):{\bf nat}:=\\ {\rm match\ }o\ {\rm with}\\ {\rm |\ Some\ }n'\Rightarrow n'\\ {\rm |\ None}\Rightarrow d\\ {\rm end.} \end{array}
```

Exercise: 2 stars (hd_opt) Using the same idea, fix the hd function from earlier so we don't have to pass a default element for the nil case.

```
Definition hd_opt (l: natlist) : natoption :=
   admit.

Example test_hd_opt1 : hd_opt [] = None.
   Admitted.

Example test_hd_opt2 : hd_opt [1] = Some 1.
   Admitted.

Example test_hd_opt3 : hd_opt [5,6] = Some 5.
   Admitted.
```

Exercise: 1 star, optional (option_elim_hd) This exercise relates your new hd_-opt to the old hd.

```
Theorem option_elim_hd : \forall (l:natlist) (default:nat), hd default l = option_elim default (hd_opt l).

Proof.

Admitted.
```

Exercise: 2 stars, recommended (beq_natlist) Fill in the definition of $beq_natlist$, which compares lists of numbers for equality. Prove that $beq_natlist\ l\ l$ yields true for every list l.

```
Fixpoint beq_natlist (l1\ l2: natlist): bool:= admit.

Example test_beq_natlist1: (beq_natlist nil nil = true). Admitted.

Example test_beq_natlist2: beq_natlist [1,2,3] [1,2,3] = true. Admitted.

Example test_beq_natlist3: beq_natlist [1,2,3] [1,2,4] = false. Admitted.

Theorem beq_natlist_refl: \forall \ l:natlist, true = beq_natlist l.

Proof. Admitted.
```

4.6 Extended Exercise: Dictionaries

As a final illustration of how fundamental data structures can be defined in Coq, here is the declaration of a simple *dictionary* data type, using numbers for both the keys and the values stored under these keys. (That is, a dictionary represents a finite map from numbers to numbers.)

Module DICTIONARY.

```
\begin{array}{l} \text{Inductive dictionary}: \ \text{Type} := \\ | \ \text{empty}: \ \text{dictionary} \\ | \ \text{record}: \ \text{nat} \rightarrow \text{nat} \rightarrow \text{dictionary} \rightarrow \text{dictionary}. \end{array}
```

This declaration can be read: "There are two ways to construct a dictionary: either using the constructor *empty* to represent an empty dictionary, or by applying the constructor record to a key, a value, and an existing dictionary to construct a dictionary with an additional key to value mapping."

```
Definition insert (key value : nat) (d : dictionary) : dictionary :=
```

```
(record key \ value \ d).
```

Here is a function *find* that searches a *dictionary* for a given key. It evaluates evaluates to *None* if the key was not found and *Some val* if the key was mapped to *val* in the dictionary. If the same key is mapped to multiple values, *find* will return the first one it finds.

```
Fixpoint find (key : nat) (d : dictionary) : natoption :=
  match d with
    empty \Rightarrow None
   | record k \ v \ d' \Rightarrow \text{if } (\text{beq\_nat } key \ k) \text{ then } (\text{Some } v) \text{ else } (\text{find } key \ d')
  end.
Exercise: 1 star (dictionary_invariant1) Complete the following proof.
Theorem dictionary_invariant1 : \forall (d : dictionary) (k \ v : nat),
   (find k (insert k \ v \ d)) = Some v.
Proof.
    Admitted.
    Exercise: 1 star (dictionary_invariant2) Complete the following proof.
Theorem dictionary_invariant2 : \forall (d : dictionary) (m \ n \ o : nat),
   (beq_nat m n) = false \rightarrow (find m d) = (find m (insert n o d)).
Proof.
    Admitted.
    End DICTIONARY.
End NATLIST.
```

Chapter 5

Library Poly

5.1 Poly: Polymorphism and Higher-Order Functions

Require Export Lists.

5.2 Polymorphism

5.2.1 Polymorphic Lists

Up to this point, we've been working with lists of numbers. Of course, interesting programs also need to be able to manipulate lists whose elements are drawn from other types – lists of strings, lists of booleans, lists of lists, etc. We *could* just define a new inductive datatype for each of these, for example...

```
Inductive boollist : Type :=
  | bool_nil : boollist
  | bool_cons : bool → boollist → boollist.
```

... but this would quickly become tedious, partly because we have to make up different constructor names for each datatype, but mostly because we would also need to define new versions of all our list manipulating functions (*length*, *rev*, etc.) for each new datatype definition.

To avoid all this repetition, Coq supports *polymorphic* inductive type definitions. For example, here is a polymorphic list datatype.

```
Inductive list (X:Type): Type :=  | nil : list X | cons : X \to  list X \to  list X.
```

This is exactly like the definition of natlist from the previous chapter, except that the nat argument to the cons constructor has been replaced by an arbitrary type X, a binding for X has been added to the header, and the occurrences of natlist in the types of the constructors

have been replaced by *list X*. (We can re-use the constructor names *nil* and *cons* because the earlier definition of *natlist* was inside of a Module definition that is now out of scope.)

What sort of thing is *list* itself? One good way to think about it is that *list* is a function from Types to Inductive definitions; or, to put it another way, *list* is a function from Types to Types. For any particular type X, the type *list* X is an Inductively defined set of lists whose elements are things of type X.

With this definition, when we use the constructors nil and cons to build lists, we need to tell Coq the type of the elements in the lists we are building – that is, nil and cons are now polymorphic constructors. Observe the types of these constructors:

Check nil.

Check cons.

(Side note on notation: In .v files, the "forall" quantifier is spelled out in letters. In the generated HTML files, \forall is usually typeset as the usual mathematical "upside down A," but you'll see the spelled-out "forall" in a few places. This is just a quirk of typesetting: there is no difference in meaning.

The " \forall X" in these types should be read as an additional argument to the constructors that determines the expected types of the arguments that follow. When nil and cons are used, these arguments are supplied in the same way as the others. For example, the list containing 2 and 1 is written like this:

```
Check (cons nat 2 (cons nat 1 (nil nat))).
```

(We've gone back to writing nil and cons explicitly here because we haven't yet defined the [] and :: notations for the new version of lists. We'll do that in a bit.)

We can now go back and make polymorphic (or "generic") versions of all the list-processing functions that we wrote before. Here is *length*, for example:

```
Fixpoint length (X: \mathsf{Type}) (l: \mathsf{list}\ X) : \mathsf{nat} := \mathsf{match}\ l \ \mathsf{with} |\ \mathsf{nil} \Rightarrow 0 |\ \mathsf{cons}\ h\ t \Rightarrow \mathsf{S}\ (\mathsf{length}\ X\ t) \ \mathsf{end}.
```

Note that the uses of nil and cons in match patterns do not require any type annotations: we already know that the list l contains elements of type X, so there's no reason to include X in the pattern. (More formally, the type X is a parameter of the whole definition of list, not of the individual constructors. We'll come back to this point later.)

As with *nil* and *cons*, we can use *length* by applying it first to a type and then to its list argument:

```
Example test_length1: length nat (cons nat 1 (cons nat 2 (nil nat))) = 2. Proof. reflexivity. Qed.
```

To use our length with other kinds of lists, we simply instantiate it with an appropriate type parameter:

```
Example test_length2 :
    length bool (cons bool true (nil bool)) = 1.
Proof. reflexivity. Qed.
```

Let's close this subsection by re-implementing a few other standard list functions on our new polymorphic lists:

```
Fixpoint app (X : Type) (l1 l2 : list X)
                       : (list X) :=
  match l1 with
    nil \Rightarrow l2
  | cons h t \Rightarrow cons X h (app X t l2) |
  end.
Fixpoint snoc (X:Type) (l:list X) (v:X) : (list X) :=
  match l with
   | \text{ nil} \Rightarrow \text{cons } X \ v \ (\text{nil } X)
   | cons h t \Rightarrow cons X h (snoc X t v) |
Fixpoint rev (X:Type) (l:list X):list X:=
  \mathtt{match}\ l with
   \mid \mathsf{nil} \Rightarrow \mathsf{nil} \ X
  |\cos h| t \Rightarrow \operatorname{snoc} X (\operatorname{rev} X t) h
  end.
Example test_rev1 :
     rev nat (cons nat 1 (cons nat 2 (nil nat)))
  = (cons nat 2 (cons nat 1 (nil nat))).
Proof. reflexivity. Qed.
Example test_rev2:
  rev bool (nil bool) = nil bool.
Proof. reflexivity. Qed.
```

Type Annotation Inference

Let's write the definition of app again, but this time we won't specify the types of any of the arguments. Will Coq still accept it?

```
Fixpoint app' X l1 l2: list X := match l1 with |\operatorname{nil} \Rightarrow l2 |\operatorname{cons} h \ t \Rightarrow \operatorname{cons} X \ h \ (\operatorname{app'} X \ t \ l2) end. Indeed it will. Let's see what type Coq has assigned to app': Check app'.
```

Check app.

It has exactly the same type type as app. Coq was able to use a process called type inference to deduce what the types of X, l1, and l2 must be, based on how they are used. For example, since X is used as an argument to cons, it must be a Type, since cons expects a Type as its first argument; matching l1 with nil and cons means it must be a list; and so on.

This powerful facility means we don't always have to write explicit type annotations everywhere, although explicit type annotations are still quite useful as documentation and sanity checks. You should try to find a balance in your own code between too many type annotations (so many that they clutter and distract) and too few (which forces readers to perform type inference in their heads in order to understand your code).

Type Argument Synthesis

Whenever we use a polymorphic function, we need to pass it one or more types in addition to its other arguments. For example, the recursive call in the body of the length function above must pass along the type X. But just like providing explicit type annotations everywhere, this is heavy and verbose. Since the second argument to length is a list of Xs, it seems entirely obvious that the first argument can only be X – why should we have to write it explicitly?

Fortunately, Coq permits us to avoid this kind of redundancy. In place of any type argument we can write the "implicit argument" _, which can be read as "Please figure out for yourself what type belongs here." More precisely, when Coq encounters a _, it will attempt to *unify* all locally available information – the type of the function being applied, the types of the other arguments, and the type expected by the context in which the application appears – to determine what concrete type should replace the _.

This may sound similar to type annotation inference – and, indeed, the two procedures rely on the same underlying mechanisms. Instead of simply omitting the types of some arguments to a function, like app' X l1 l2 : list X := we can also replace the types with $_$, like app' $(X : _)$ (l1 l2 : $_$) : list X := which tells Coq to attempt to infer the missing information, just as with argument synthesis.

Using implicit arguments, the *length* function can be written like this:

```
Fixpoint length' (X: \mathsf{Type}) (l: \mathsf{list}\ X): \mathsf{nat}:= \mathsf{match}\ l with |\mathsf{nil}\Rightarrow 0 |\mathsf{cons}\ h\ t\Rightarrow \mathsf{S} (length' _{-} t) end.
```

In this instance, we don't save much by writing $_$ instead of X. But in many cases the difference can be significant. For example, suppose we want to write down a list containing the numbers 1, 2, and 3. Instead of writing this...

```
Definition list123 := cons nat 1 (cons nat 2 (cons nat 3 (nil nat))).
```

...we can use argument synthesis to write this:

```
Definition list123' := cons _1 (cons _2 (cons _3 (nil _))).
```

Implicit Arguments

If fact, we can go further. To avoid having to sprinkle _'s throughout our programs, we can tell Coq always to infer the type argument(s) of a given function.

```
Implicit Arguments nil [[X]].
Implicit Arguments cons [[X]].
Implicit Arguments length [[X]].
Implicit Arguments app [[X]].
Implicit Arguments rev [[X]].
Implicit Arguments snoc [[X]].
Definition list123'' := cons 1 (cons 2 (cons 3 nil)).
Check (length list123'').
```

Alternatively, we can declare an argument to be implicit while defining the function itself, by surrounding the argument in curly braces. For example:

```
Fixpoint length" \{X: \mathsf{Type}\}\ (l: \mathsf{list}\ X) : \mathsf{nat} := \mathsf{match}\ l \ \mathsf{with} \ |\ \mathsf{nil} \Rightarrow 0 \ |\ \mathsf{cons}\ h\ t \Rightarrow \mathsf{S}\ (\mathsf{length}''\ t) \ \mathsf{end}.
```

(Note that we didn't even have to provide a type argument to the recursive call to length''.) We will use this style whenever possible, although we will continue to use use explicit Implicit Argument declarations for Inductive constructors.

One small problem with declaring arguments Implicit is that, occasionally, Coq does not have enough local information to determine a type argument; in such cases, we need to tell Coq that we want to give the argument explicitly this time, even though we've globally declared it to be Implicit. For example, if we write:

If we uncomment this definition, Coq will give us an error, because it doesn't know what type argument to supply to *nil*. We can help it by providing an explicit type declaration (so that Coq has more information available when it gets to the "application" of *nil*):

```
Definition mynil: list nat := nil.
```

Alternatively, we can force the implicit arguments to be explicit by prefixing the function name with @.

```
Check @nil.
```

```
Definition mynil' := @nil nat.
```

Using argument synthesis and implicit arguments, we can define convenient notation for lists, as before. Since we have made the constructor type arguments implicit, Coq will know to automatically infer these when we use the notations.

```
Notation "x :: y" := (cons x y)
                       (at level 60, right associativity).
Notation "[]" := nil.
Notation "[x, ..., y]" := (cons x .. (cons y []) ..).
Notation "x ++ y" := (app x y)
                       (at level 60, right associativity).
   Now lists can be written just the way we'd hope:
Definition list 123 := [1, 2, 3].
```

Exercises: Polymorphic Lists

Exercise: 2 stars, optional (poly_exercises) Here are a few simple exercises, just like ones in the *Lists* chapter, for practice with polymorphism. Fill in the definitions and complete the proofs below.

```
Fixpoint repeat (X : Type) (n : X) (count : nat) : list X :=
  admit.
Example test_repeat1:
  repeat bool true 2 = \cos true (cons true nil).
   Admitted.
Theorem nil_app : \forall X:Type, \forall l:list X,
  app [] l = l.
Proof.
    Admitted.
Theorem rev_snoc : \forall X : Type,
                           \forall v: X
                           \forall s :  list X,
  rev (snoc s v) = v :: (rev s).
Proof.
    Admitted.
Theorem rev_involutive : \forall X : Type, \forall l : list X,
  rev (rev l) = l.
Proof.
    Admitted.
Theorem snoc_with_append : \forall X : Type,
                               \forall l1 l2 : list X,
                                \forall v: X
  snoc (l1 ++ l2) v = l1 ++ (snoc l2 v).
Proof.
   Admitted.
```

5.2.2 Polymorphic Pairs

Following the same pattern, the type definition we gave in the last chapter for pairs of numbers can be generalized to *polymorphic pairs* (or *products*):

```
Inductive prod (X \ Y : \mathsf{Type}) : \mathsf{Type} := \mathsf{pair} : X \to Y \to \mathsf{prod} \ X \ Y. Implicit Arguments pair [[X] \ [Y]].
```

As with lists, we make the type arguments implicit and define the familiar concrete notation.

```
Notation "(x, y)" := (pair x y).
```

We can also use the Notation mechanism to define the standard notation for pair types:

```
Notation "X * Y" := (\operatorname{prod} X Y) : type\_scope.
```

(The annotation: type_scope tells Coq that this abbreviation should be used when parsing types. This avoids a clash with the multiplication symbol.)

A note of caution: it is easy at first to get (x,y) and $X \times Y$ confused. Remember that (x,y) is a value built from two other values; $X \times Y$ is a type built from two other types. If x has type X and y has type Y, then (x,y) has type $X \times Y$.

The first and second projection functions now look pretty much as they would in any functional programming language.

```
Definition fst \{X \mid Y : \mathsf{Type}\}\ (p:X\times Y):X:= match p with (x,y)\Rightarrow x end.

Definition snd \{X\mid Y : \mathsf{Type}\}\ (p:X\times Y):Y:= match p with (x,y)\Rightarrow y end.
```

The following function takes two lists and combines them into a list of pairs. In many functional programming languages, it is called *zip*. We call it *combine* for consistency with Coq's standard library. Note that the pair notation can be used both in expressions and in patterns...

```
Fixpoint combine \{X \mid Y : \mathsf{Type}\}\ (lx : \mathsf{list} \mid X) \ (ly : \mathsf{list} \mid Y)
: \mathsf{list} \ (X \times Y) :=
\mathsf{match} \ (lx, ly) \ \mathsf{with}
|\ ([], \_) \Rightarrow []
|\ (\_, []) \Rightarrow []
|\ (x :: tx, \ y :: ty) \Rightarrow (x, y) :: \ (\mathsf{combine} \ tx \ ty)
\mathsf{end}.
```

Indeed, when no ambiguity results, we can even drop the enclosing parens:

```
Fixpoint combine' \{X \mid Y : \mathtt{Type}\}\ (lx : \mathtt{list} \mid X)\ (ly : \mathtt{list} \mid Y) : list (X \times Y) := match (lx, ly) with [], - \Rightarrow []
```

```
| \_,[] \Rightarrow []
| x::tx, y::ty \Rightarrow (x,y) :: (combine' tx ty)
end.
```

Exercise: 1 star, optional (combine_checks) Try answering the following questions on paper and checking your answers in coq:

- What is the type of combine (i.e., what does Check @combine print?)
- What does Eval simpl in (combine 1,2 false, false, true, true). print? \square

Exercise: 2 stars, recommended (split) The function split is the right inverse of combine: it takes a list of pairs and returns a pair of lists. In many functional programing languages, this function is called *unzip*.

Uncomment the material below and fill in the definition of split. Make sure it passes the given unit tests.

(If you're reading the HTML version of this file, note that there's an unresolved type setting problem in the example: several square brackets are missing. Refer to the .v file for the correct version. \Box

5.2.3 Polymorphic Options

One last polymorphic type for now: *polymorphic options*. The type declaration generalizes the one for *natoption* in the previous chapter:

```
Inductive option (X:Type): Type :=
    Some : X \to \mathbf{option} \ X
   None : option X.
Implicit Arguments Some ||X||.
Implicit Arguments None [X].
    We can now rewrite the index function so that it works with any type of lists.
Fixpoint index \{X : \mathsf{Type}\}\ (n : \mathsf{nat})
                    (l: list X): option X:=
  \mathtt{match}\ l\ \mathtt{with}
    [] \Rightarrow \mathsf{None}
  a :: l' \Rightarrow \text{if beq\_nat } n \text{ } \bigcirc \text{ then Some } a \text{ else index } (\text{pred } n) \text{ } l'
  end.
Example test_index1 : index 0 [4,5,6,7] = Some 4.
Proof. reflexivity. Qed.
Example test_index2 : index 1 [[1], [2]] = Some [2].
Proof. reflexivity. Qed.
Example test_index3 : index 2 [true] = None.
Proof. reflexivity. Qed.
```

Exercise: 1 star, optional (hd_opt_poly) Complete the definition of a polymorphic version of the hd_opt function from the last chapter. Be sure that it passes the unit tests below.

```
Definition \mathsf{hd}-opt \{X : \mathsf{Type}\}\ (l : \mathsf{list}\ X) : \mathsf{option}\ X := \mathsf{admit}.
```

Once again, to force the implicit arguments to be explicit, we can use @ before the name of the function.

```
Check @hd_opt.

Example test_hd_opt1 : hd_opt [1,2] = Some 1.

Admitted.

Example test_hd_opt2 : hd_opt [[1],[2]] = Some [1].

Admitted.
```

5.3 Functions as Data

5.3.1 Higher-Order Functions

Like many other modern programming languages – including all functional languages (ML, Haskell, Scheme, etc.) – Coq treats functions as first-class citizens, allowing functions to be passed as arguments to other functions, returned as results, stored in data structures, etc.

Functions that manipulate other functions are often called *higher-order* functions. Here's a simple one:

```
Definition doit3times \{X: \mathtt{Type}\}\ (f:X \to X)\ (n:X): X:=f\ (f\ (f\ n)).
```

The argument f here is itself a function (from X to X); the body of doit3times applies f three times to some value n.

Check @doit3times.

```
Example test_doit3times: doit3times minustwo 9 = 3. 
Proof. reflexivity. Qed. 
Example test_doit3times': doit3times negb true = false. 
Proof. reflexivity. Qed.
```

5.3.2 Partial Application

In fact, the multiple-argument functions we have already seen are also examples of passing functions as data. To see why, recall the type of plus.

Check plus.

Each \rightarrow in this expression is actually a binary operator on types. (This is the same as saying that Coq primitively supports only one-argument functions – do you see why?) This operator is right-associative, so the type of plus is really a shorthand for $nat \rightarrow (nat \rightarrow nat)$ – i.e., it can be read as saying that "plus is a one-argument function that takes a nat and returns a one-argument function that takes another nat and returns a nat." In the examples above, we have always applied plus to both of its arguments at once, but if we like we can supply just the first. This is called partial application.

```
Definition plus3 := plus 3.

Check plus3.

Example test_plus3 : plus3 4 = 7.

Proof. reflexivity. Qed.

Example test_plus3' : doit3times plus3 0 = 9.

Proof. reflexivity. Qed.

Example test_plus3'' : doit3times (plus 3) 0 = 9.

Proof. reflexivity. Qed.
```

5.3.3 Digression: Currying

Exercise: 2 stars, optional (currying) In Coq, a function $f: A \to B \to C$ really has the type $A \to (B \to C)$. That is, if you give f a value of type A, it will give you function $f': B \to C$. If you then give f' a value of type B, it will return a value of type C. This allows for partial application, as in *plus3*. Processing a list of arguments with functions that return functions is called *currying*, in honor of the logician Haskell Curry.

Conversely, we can reinterpret the type $A \to B \to C$ as $(A \times B) \to C$. This is called *uncurrying*. With an uncurried binary function, both arguments must be given at once as a pair; there is no partial application.

We can define currying as follows:

```
Definition prod_curry \{X \ Y \ Z : \mathtt{Type}\} (f: X \times Y \to Z) \ (x: X) \ (y: Y) : Z := f \ (x, y).
```

As an exercise, define its inverse, *prod_uncurry*. Then prove the theorems below to show that the two are inverses.

```
Definition prod_uncurry \{X \ Y \ Z : \mathtt{Type}\} (f: X \to Y \to Z) \ (p: X \times Y) : Z := \mathit{admit}.
```

(Thought exercise: before running these commands, can you calculate the types of $prod_curry$ and $prod_uncurry$?)

```
Check @prod_curry. Check @prod_uncurry. Theorem uncurry_curry: \forall (X \ Y \ Z : \texttt{Type}) \ (f: X \to Y \to Z) \ x \ y,  prod_curry (prod_uncurry f) \ x \ y = f \ x \ y.
```

```
\begin{array}{c} {\sf Proof.} \\ {\it Admitted.} \end{array} Theorem curry_uncurry : \forall \; (X \; Y \; Z : {\sf Type}) \\ \qquad \qquad \qquad (f: (X \times Y) \to Z) \; (p: X \times Y), \\ {\sf prod\_uncurry} \; ({\sf prod\_curry} \; f) \; p = f \; p. \\ {\sf Proof.} \\ {\it Admitted.} \\ \square \end{array}
```

5.3.4 Filter

Here is a useful higher-order function, which takes a list of Xs and a predicate on X (a function from X to bool) and "filters" the list, returning a new list containing just those elements for which the predicate returns true.

```
Fixpoint filter \{X: \mathsf{Type}\}\ (test:\ X \to \mathsf{bool})\ (l: \mathsf{list}\ X) := (\mathsf{list}\ X) := \mathsf{match}\ l \ \mathsf{with} \ |\ [] \Rightarrow [] \ |\ h ::\ t \Rightarrow \mathsf{if}\ test\ h\ \mathsf{then}\ h ::\ (\mathsf{filter}\ test\ t) \ \mathsf{else}\ \mathsf{filter}\ test\ t \ \mathsf{end}.
```

For example, if we apply *filter* to the predicate *evenb* and a list of numbers l, it returns a list containing just the even members of l.

We can use *filter* to give a concise version of the *countoddmembers* function from the *Lists* chapter.

```
Definition countoddmembers' (l:list nat) : nat :=
  length (filter oddb l).

Example test_countoddmembers'1: countoddmembers' [1,0,3,1,4,5] = 4.
Proof. reflexivity. Qed.
Example test_countoddmembers'2: countoddmembers' [0,2,4] = 0.
Proof. reflexivity. Qed.
```

Example test_countoddmembers'3: countoddmembers' nil = 0. Proof. reflexivity. Qed.

5.3.5 Anonymous Functions

It is a little annoying to be forced to define the function $length_is_1$ and give it a name just to be able to pass it as an argument to filter, since we will probably never use it again. Moreover, this is not an isolated example. When using higher-order functions, we often want to pass as arguments "one-off" functions that we will never use again; having to give each of these functions a name would be tedious.

Fortunately, there is a better way. It is also possible to construct a function "on the fly" without declaring it at the top level or giving it a name; this is analogous to the notation we've been using for writing down constant lists, natural numbers, and so on.

```
Example test_anon_fun': doit3times (fun n \Rightarrow n \times n) 2 = 256. Proof. reflexivity. Qed.
```

Here is the motivating example from before, rewritten to use an anonymous function.

Example test_filter2':

```
filter (fun l \Rightarrow \text{beq\_nat} (length l) 1) 
 [ [1, 2], [3], [4], [5,6,7], [], [8] ] 
 = [ [3], [4], [8] ]. 
 Proof. reflexivity. Qed.
```

Exercise: 2 stars (filter_even_gt7) Use filter (instead of Fixpoint) to write a Coq function filter_even_gt7 which takes a list of natural numbers as input and keeps only those numbers which are even and greater than 7.

```
Definition filter_even_gt7 (l : list nat) : list nat := admit.

Example test_filter_even_gt7_1 : filter_even_gt7 [1,2,6,9,10,3,12,8] = [10,12,8]. Admitted.

Example test_filter_even_gt7_2 : filter_even_gt7 [5,2,6,19,129] = []. Admitted.
```

Exercise: 3 stars (partition) Use *filter* to write a Coq function *partition*: partition: forall X : Type, $(X -> bool) -> list X -> list X * list X Given a set X, a test function of type <math>X \to bool$ and a *list X*, *partition* should return a pair of lists. The first member of the pair is the sublist of the original list containing the elements that satisfy the test, and the

second is the sublist containing those that fail the test. The order of elements in the two sublists should be the same as their order in the original list.

```
Definition partition \{X: \mathsf{Type}\}\ (test: X \to \mathbf{bool})\ (l: \mathsf{list}\ X) : \mathsf{list}\ X \times \mathsf{list}\ X := admit. 
 Example test_partition1: partition oddb [1,2,3,4,5] = ([1,3,5],[2,4]). 
 Admitted. 
 Example test_partition2: partition (fun x \Rightarrow \mathsf{false})\ [5,9,0] = ([],[5,9,0]). 
 Admitted. 
 \Box
```

5.3.6 Map

Another handy higher-order function is called *map*.

```
 \begin{array}{c} \texttt{Fixpoint map} \; \{X \; \; Y : \texttt{Type}\} \; (f : X \to Y) \; (l : \textbf{list} \; X) \\ & : \; (\textbf{list} \; \; Y) := \\ \texttt{match} \; l \; \texttt{with} \\ \mid \; [] \; \Rightarrow \; [] \\ \mid \; h \; : \; t \; \Rightarrow \; (f \; h) \; : : \; (\texttt{map} \; f \; t) \\ \texttt{end}. \end{array}
```

It takes a function f and a list l = [n1, n2, n3, ...] and returns the list $[f \ n1, f \ n2, f \ n3,...]$, where f has been applied to each element of l in turn. For example:

```
Example test_map1: map (plus 3) [2,0,2] = [5,3,5]. Proof. reflexivity. Qed.
```

The element types of the input and output lists need not be the same (map takes two type arguments, X and Y). This version of map can thus be applied to a list of numbers and a function from numbers to booleans to yield a list of booleans:

```
Example test_map2: map oddb [2,1,2,5] = [false,true,false,true]. Proof. reflexivity. Qed.
```

It can even be applied to a list of numbers and a function from numbers to *lists* of booleans to yield a list of lists of booleans:

Example test_map3:

```
map (fun n \Rightarrow [evenb n,oddb n]) [2,1,2,5] = [[true,false],[false,true],[true,false],[false,true]]. Proof. reflexivity. Qed.
```

Exercise: 3 stars, optional (map_rev) Show that map and rev commute. You may need to define an auxiliary lemma.

```
Theorem map_rev : \forall (X \ Y : Type) \ (f : X \to Y) \ (l : list X),
```

```
\begin{aligned} & \text{map } f \text{ (rev } l) = \text{rev } (\text{map } f \text{ } l). \\ & \text{Proof.} \\ & & Admitted. \\ & & \Box \end{aligned}
```

Exercise: 2 stars, recommended (flat_map) The function map maps a $list\ X$ to a $list\ Y$ using a function of type $X \to Y$. We can define a similar function, $flat_map$, which maps a $list\ X$ to a $list\ Y$ using a function f of type $X \to list\ Y$. Your definition should work by 'flattening' the results of f, like so: flat_map (fun n = n, n+1, n+2) 1,5,10 = 1, 2, 3, 5, 6, 7, 10, 11, 12.

```
Fixpoint flat_map \{X \ Y : \texttt{Type}\}\ (f : X \to \texttt{list}\ Y)\ (l : \texttt{list}\ X) : (\texttt{list}\ Y) := admit. 
 Example test_flat_map1: flat_map (fun n \Rightarrow [n,n,n]) [1,5,4] = [1,\ 1,\ 1,\ 5,\ 5,\ 5,\ 4,\ 4,\ 4]. Admitted.
```

Lists are not the only inductive type that we can write a map function for. Here is the definition of map for the option type:

```
Definition option_map \{X \mid Y : \mathsf{Type}\}\ (f : X \to Y)\ (xo : \mathsf{option}\ X) : \mathsf{option}\ Y := match xo with |\ \mathsf{None} \Rightarrow \mathsf{None}\ | |\ \mathsf{Some}\ x \Rightarrow \mathsf{Some}\ (f\ x) end.
```

Exercise: 2 stars, optional (implicit_args) The definitions and uses of *filter* and map use implicit arguments in many places. Replace the curly braces around the implicit arguments with parentheses, and then fill in explicit type parameters where necessary and use Coq to check that you've done so correctly. This exercise is not to be turned in; it is probably easiest to do it on a copy of this file that you can throw away afterwards. \square

5.3.7 Fold

An even more powerful higher-order function is called **fold**. This function is the inspiration for the "reduce" operation that lies at the heart of Google's map/reduce distributed programming framework.

```
Fixpoint fold \{X \ Y : \texttt{Type}\}\ (f \colon X \to Y \to Y)\ (l : \texttt{list}\ X)\ (b \colon Y) \colon Y := \texttt{match}\ l \ \texttt{with} \ |\ \texttt{nil} \Rightarrow b
```

```
| h :: t \Rightarrow f \ h \ (\mathsf{fold} \ f \ t \ b) end.
```

Intuitively, the behavior of the fold operation is to insert a given binary operator f between every pair of elements in a given list. For example, fold plus [1,2,3,4] intuitively means 1+2+3+4. To make this precise, we also need a "starting element" that serves as the initial second input to f. So, for example, fold plus 1,2,3,4 0 yields 1 + (2 + (3 + (4 + 0))). Here are some more examples:

```
Check (fold plus).
Eval simpl in (fold plus [1,2,3,4] 0).

Example fold_example1: fold mult [1,2,3,4] 1 = 24.

Proof. reflexivity. Qed.

Example fold_example2: fold andb [true,true,false,true] true = false.

Proof. reflexivity. Qed.

Example fold_example3: fold app [[1],[],[2,3],[4]] [] = [1,2,3,4].

Proof. reflexivity. Qed.
```

Exercise: 1 star, optional (fold_types_different) Observe that the type of fold is parameterized by two type variables, X and Y, and the parameter f is a binary operator that takes an X and a Y and returns a Y. Can you think of a situation where it would be useful for X and Y to be different?

5.3.8 Functions For Constructing Functions

Most of the higher-order functions we have talked about so far take functions as arguments. Now let's look at some examples involving returning functions as the results of other functions.

To begin, here is a function that takes a value x (drawn from some type X) and returns a function from nat to X that yields x whenever it is called, ignoring its nat argument.

```
Definition constfun \{X : \mathsf{Type}\}\ (x : X) : \mathsf{nat} {\to} X := \mathsf{fun}\ (k : \mathsf{nat}) \Rightarrow x.
Definition ftrue := constfun true.

Example constfun_example1 : ftrue 0 = true.

Proof. reflexivity. Qed.

Example constfun_example2 : (constfun 5) 99 = 5.

Proof. reflexivity. Qed.
```

Similarly, but a bit more interestingly, here is a function that takes a function f from numbers to some type X, a number k, and a value x, and constructs a function that behaves exactly like f except that, when called with the argument k, it returns x.

```
Definition override \{X: \mathsf{Type}\}\ (f: \mathsf{nat} \to X)\ (k:\mathsf{nat})\ (x:X): \mathsf{nat} \to X:=
```

```
fun (k':nat) \Rightarrow if beq_nat k k' then x else f k'.
```

For example, we can apply override twice to obtain a function from numbers to booleans that returns false on 1 and 3 and returns true on all other arguments.

```
Definition fmostlytrue := override (override ftrue 1 false) 3 false.
```

```
Example override_example1 : fmostlytrue 0 = \text{true}.
```

Proof. reflexivity. Qed.

Example override_example2 : fmostlytrue 1 = false.

Proof. reflexivity. Qed.

Example override_example3 : fmostlytrue 2 = true.

Proof. reflexivity. Qed.

Example override_example4 : fmostlytrue 3 = false.

Proof. reflexivity. Qed.

Exercise: 1 star (override_example) Before starting to work on the following proof, make sure you understand exactly what the theorem is saying and can paraphrase it in your own words. The proof itself is straightforward.

```
Theorem override_example : \forall (b:bool),
  (override (constfun b) 3 true) 2 = b.
Proof.
    Admitted.
```

We'll use function overriding heavily in parts of the rest of the course, and we will end up needing to know quite a bit about its properties. To prove these properties, though, we need to know about a few more of Coq's tactics; developing these is the main topic of the rest of the chapter.

Optional Material 5.4

5.4.1 Non-Uniform Inductive Families (GADTs)

This section needs more text!

Recall the definition of lists of booleans: Inductive boollist: Type := boolnil: boollist boolcons: bool -> boollist -> boollist.

We saw how it could be generalized to "polymorphic lists" with elements of an arbitrary type X. Here's another way of generalizing it: an inductive family of "length-indexed" lists of booleans:

```
Inductive boolllist : nat \rightarrow Type :=
   boollnil: boolllist ()
 boollons : \forall n, \mathbf{bool} \rightarrow \mathbf{boolllist} \ n \rightarrow \mathbf{boolllist} \ (S \ n).
```

```
Implicit Arguments boolkoons [n].
Check (boolloons true (boolloons false (boolloons true boollnil))).
Fixpoint blapp \{n1\} (l1: boolllist n1)
                    \{n2\} (l2: boolllist n2)
                 : boolllist (n1 + n2) :=
  match l1 with
  | boollnil \Rightarrow l2
   | boollcons _{-}h t \Rightarrow boollcons h (blapp t l2)
    Of course, these generalizions can be combined. Here's the length-indexed polymorphic
version:
Inductive llist (X:Type) : nat \rightarrow Type :=
  lnil: Ilist X \bigcirc
| \text{ lcons} : \forall n, X \rightarrow \text{ llist } X \ n \rightarrow \text{ llist } X \ (S \ n).
Implicit Arguments [X].
Implicit Arguments Icons [X] [n].
Check (Icons true (Icons false (Icons true Inil))).
Fixpoint lapp (X:Type)
                  \{n1\} (l1: llist X n1)
                  \{n2\} (l2: llist X n2)
                : llist X (n1 + n2) :=
  match l1 with
  | \text{Inil} \Rightarrow l2
  | lcons _h t \Rightarrow lcons h (lapp X t l2)
  end.
```

5.5 More About Coq

5.5.1 The apply Tactic

We often encounter situations where the goal to be proved is exactly the same as some hypothesis in the context or some previously proved lemma.

```
Theorem silly1: \forall (n \ m \ o \ p : nat), n = m \rightarrow [n,o] = [n,p] \rightarrow [n,o] = [m,p].

Proof.

intros n \ m \ o \ p \ eq1 \ eq2.

rewrite \leftarrow eq1.
```

```
apply eq2. Qed.
```

The apply tactic also works with *conditional* hypotheses and lemmas: if the statement being applied is an implication, then the premises of this implication will be added to the list of subgoals needing to be proved.

```
Theorem silly2: \forall (n \ m \ o \ p : \mathsf{nat}), n = m \rightarrow (\forall \ (q \ r : \mathsf{nat}), \ q = r \rightarrow [q,o] = [r,p]) \rightarrow [n,o] = [m,p].

Proof.

intros n \ m \ o \ p \ eq1 \ eq2.
apply eq2. apply eq2. apply eq1. Qed.
```

You may find it instructive to experiment with this proof and see if there is a way to complete it using just rewrite instead of apply.

Typically, when we use apply H, the statement H will begin with a \forall binding some universal variables. When Coq matches the current goal against the conclusion of H, it will try to find appropriate values for these variables. For example, when we do apply eq2 in the following proof, the universal variable q in eq2 gets instantiated with n and r gets instantiated with m.

```
Theorem silly2a : \forall (n \ m : nat), (n,n) = (m,m) \rightarrow (\forall (q \ r : nat), (q,q) = (r,r) \rightarrow [q] = [r]) \rightarrow [n] = [m].

Proof.

intros n \ m \ eq1 \ eq2.

apply eq2. apply eq1. Qed.
```

Exercise: 2 stars, optional (silly_ex) Complete the following proof without using simpl.

```
Theorem silly_ex :  (\forall \ n, \ \text{evenb} \ n = \text{true} \rightarrow \text{oddb} \ (\textbf{S} \ n) = \text{true}) \rightarrow \\ \text{evenb} \ 3 = \text{true} \rightarrow \\ \text{oddb} \ 4 = \text{true}.  Proof.
```

Admitted.

To use the apply tactic, the (conclusion of the) fact being applied must match the goal exactly – for example, apply will not work if the left and right sides of the equality are swapped.

```
Theorem silly3_firsttry : \forall (n : nat),
true = beq_nat n 5 \rightarrow
beq_nat (S (S n)) 7 = true.
```

```
Proof. intros n H. simpl. Admitted.
```

In this case we can use the **symmetry** tactic, which switches the left and right sides of an equality in the goal.

```
Theorem silly3 : \forall (n : nat),

true = beq_nat n 5 \rightarrow

beq_nat (S (S n)) 7 = true.

Proof.

intros n H.

symmetry.

simpl. apply H. Qed.

Exercise: 3 stars, recommended (apply_exercise1) Theorem rev_exercise1 : \forall (l l' : list nat),

l = rev l' \rightarrow

l' = rev l.

Proof.

Admitted.
```

Exercise: 1 star (apply_rewrite) Briefly explain the difference between the tactics apply and rewrite. Are there situations where both can usefully be applied?

5.5.2 The unfold Tactic

Sometimes, a proof will get stuck because Coq doesn't automatically expand a function call into its definition. (This is a feature, not a bug: if Coq automatically expanded everything possible, our proof goals would quickly become enormous – hard to read and slow for Coq to manipulate!)

```
Theorem unfold_example_bad : \forall m \ n, 3 + n = m \rightarrow plus 3 n + 1 = m + 1.

Proof.
intros m \ n \ H.

Admitted.
```

The unfold tactic can be used to explicitly replace a defined name by the right-hand side of its definition.

Theorem unfold_example : $\forall m n$,

```
3+n=m \rightarrow \text{plus} 3 \ n+1=m+1. Proof.
intros m \ n \ H.
unfold plus3.
rewrite \rightarrow H.
reflexivity. Qed.
```

Now we can prove a first property of *override*: If we override a function at some argument k and then look up k, we get back the overridden value.

```
Theorem override_eq: \forall \{X: \texttt{Type}\} \ x \ k \ (f: \texttt{nat} \rightarrow X), (override f \ k \ x) \ k = x.

Proof.

intros X \ x \ k \ f.

unfold override.

rewrite \leftarrow beq\_nat\_refl.

reflexivity. Qed.
```

This proof was straightforward, but note that it requires unfold to expand the definition of override.

```
Exercise: 2 stars (override_neq) Theorem override_neq : \forall \{X: \texttt{Type}\} \ x1 \ x2 \ k1 \ k2 \ (f: \texttt{nat} \rightarrow X), f \ k1 = x1 \rightarrow \texttt{beq\_nat} \ k2 \ k1 = \mathsf{false} \rightarrow \texttt{(override} \ f \ k2 \ x2) \ k1 = x1. Proof. Admitted.
```

As the inverse of unfold, Coq also provides a tactic fold, which can be used to "unexpand" a definition. It is used much less often.

5.5.3 Inversion

Recall the definition of natural numbers: Inductive nat : Type := |O:nat|S:nat-> nat. It is clear from this definition that every number has one of two forms: either it is the constructor O or it is built by applying the constructor S to another number. But there is more here than meets the eye: implicit in the definition (and in our informal understanding of how datatype declarations work in other programming languages) are two other facts:

- The constructor S is *injective*. That is, the only way we can have $S \ n = S \ m$ is if n = m.
- The constructors O and S are disjoint. That is, O is not equal to S n for any n.

Similar principles apply to all inductively defined types: all constructors are injective, and the values built from distinct constructors are never equal. For lists, the *cons* constructor is injective and *nil* is different from every non-empty list. For booleans, *true* and *false* are unequal. (Since neither *true* nor *false* take any arguments, their injectivity is not an issue.)

Coq provides a tactic, called inversion, that allows us to exploit these principles in making proofs.

The inversion tactic is used like this. Suppose H is a hypothesis in the context (or a previously proven lemma) of the form c a1 a2 ... an = d b1 b2 ... bm for some constructors c and d and arguments a1 ... an and b1 ... bm. Then inversion H instructs Coq to "invert" this equality to extract the information it contains about these terms:

- If c and d are the same constructor, then we know, by the injectivity of this constructor, that a1 = b1, a2 = b2, etc.; inversion H adds these facts to the context, and tries to use them to rewrite the goal.
- If c and d are different constructors, then the hypothesis H is contradictory. That is, a false assumption has crept into the context, and this means that any goal whatsoever is provable! In this case, inversion H marks the current goal as completed and pops it off the goal stack.

The inversion tactic is probably easier to understand by seeing it in action than from general descriptions like the above. Below you will find example theorems that demonstrate the use of inversion and exercises to test your understanding.

```
Theorem eq_add_S : \forall (n \ m : \mathbf{nat}), S \ n = S \ m \rightarrow n = m.

Proof.

intros n \ m \ eq. inversion eq. reflexivity. Qed.

Theorem silly4 : \forall (n \ m : \mathbf{nat}), [n] = [m] \rightarrow n = m.

Proof.

intros n \ o \ eq. inversion eq. reflexivity. Qed.
```

As a convenience, the inversion tactic can also destruct equalities between complex values, binding multiple variables as it goes.

```
Theorem silly5 : \forall (n \ m \ o : \mathbf{nat}), [n,m] = [o,o] \rightarrow [n] = [m].
```

Proof.

intros n m o eq. inversion eq. reflexivity. Qed.

```
Exercise: 1 star (sillyex1) Example sillyex1: \forall (X : Type) (x \ y \ z : X) (l \ j : list \ X),
      x :: y :: l = z :: j \rightarrow
      y :: l = x :: j \rightarrow
      x = y.
Proof.
    Admitted.
Theorem silly6 : \forall (n : nat),
      S n = O \rightarrow
      2 + 2 = 5.
Proof.
  intros n contra. inversion contra. Qed.
Theorem silly 7: \forall (n \ m : nat),
      false = true \rightarrow
      [n] = [m].
Proof.
  intros n \ m \ contra. inversion contra. Qed.
Exercise: 1 star (sillyex2) Example sillyex2: \forall (X : Type) (x \ y \ z : X) (l \ j : list \ X),
      x :: y :: l = [] \rightarrow
      y :: l = z :: j \rightarrow
      x = z.
Proof.
    Admitted.
    While the injectivity of constructors allows us to reason \forall (n \ m : nat), S \ n = S \ m \to n
= m, the reverse direction of the implication, provable by standard equational reasoning, is
a useful fact to record for cases we will see several times.
Lemma eq_remove_S : \forall n m,
  n = m \rightarrow S n = S m.
Proof. intros n m eq. rewrite \rightarrow eq. reflexivity. Qed.
    Here's another illustration of inversion. This is a slightly roundabout way of stating
a fact that we have already proved above. The extra equalities force us to do a little more
equational reasoning and exercise some of the tactics we've seen recently.
Theorem length_snoc': \forall (X : Type) (v : X)
                                      (l: \mathsf{list}\ X)\ (n: \mathsf{nat}),
      length l = n \rightarrow
      length (snoc l v) = S n.
Proof.
  intros X \ v \ l. induction l as [|\ v'\ l'].
```

Case "l = []". intros n eq. rewrite \leftarrow eq. reflexivity.

```
Case \; "l = v' :: l'". \; intros \; n \; eq. \; simpl. \; destruct \; n \; as \; [| \; n']. SCase \; "n = 0". \; inversion \; eq. SCase \; "n = S \; n'". apply eq_remove_S. apply IHl'. \; inversion \; eq. \; reflexivity. \; Qed.
```

5.5.4 Varying the Induction Hypothesis

Here is a more realistic use of inversion to prove a property that is useful in many places later on...

```
Theorem beq_nat_eq_FAILED: \forall n \ m, true = beq_nat n \ m \to n = m.

Proof.

intros n \ m \ H. induction n as [| \ n'].

Case \ "n = 0".

destruct m as [| \ m'].

SCase \ "m = 0". reflexivity.

SCase \ "m = S \ m'". simpl in H. inversion H.

Case \ "n = S \ n'".

destruct m as [| \ m'].

SCase \ "m = 0". simpl in H. inversion H.

SCase \ "m = S \ m'".

apply eq_remove_S.

Admitted.
```

The inductive proof above fails because we've set up things so that the induction hypothesis (in the second subgoal generated by the induction tactic) is

```
true = beg\_nat \ n' \ m \rightarrow n' = m \ .
```

This hypothesis makes a statement about n' together with the particular natural number m – that is, the number m, which was introduced into the context by the intros at the top of the proof, is "held constant" in the induction hypothesis. This induction hypothesis is not strong enough to make the induction step of the proof go through.

If we set up the proof slightly differently by introducing just n into the context at the top, then we get an induction hypothesis that makes a stronger claim:

```
\forall m : nat, true = beg\_nat \ n' \ m \rightarrow n' = m
```

Setting up the induction hypothesis this way makes the proof of beq_nat_eq go through:

```
Theorem beq_nat_eq : \forall n \ m, true = beq_nat n \ m \to n = m.

Proof.

intros n. induction n as [\mid n'].

Case \ "n = 0".

intros m. destruct m as [\mid m'].

SCase \ "m = 0". reflexivity.

SCase \ "m = S \ m'". simpl. intros contra. inversion contra.
```

```
Case "n = S n'".

intros m. destruct m as [|m'].

SCase "m = 0". simpl. intros contra. inversion contra.

SCase "m = S m'". simpl. intros H.

apply eq_remove_S. apply IHn'. apply H. Qed.
```

Similar issues will come up in *many* of the proofs below. If you ever find yourself in a situation where the induction hypothesis is insufficient to establish the goal, consider going back and doing fewer intros to make the IH stronger.

Exercise: 2 stars (beq_nat_eq_informal) Give an informal proof of beq_nat_eq.

Exercise: 3 stars (beq_nat_eq') We can also prove beq_nat_eq by induction on m, though we have to be a little careful about which order we introduce the variables, so that we get a general enough induction hypothesis — this is done for you below. Finish the following proof. To get maximum benefit from the exercise, try first to do it without looking back at the one above.

```
Theorem beq_nat_eq': \forall m \ n, beq_nat n \ m = \text{true} \rightarrow n = m. Proof.

intros m. induction m as [\mid m']. Admitted.
```

Practice Session

Exercise: 2 stars, optional (practice) Some nontrivial but not-too-complicated proofs to work together in class, and some for you to work as exercises. Some of the exercises may involve applying lemmas from earlier lectures or homeworks.

```
Theorem beq_nat_0_l : \forall n, true = beq_nat 0 \ n \rightarrow 0 = n. Proof. Admitted.

Theorem beq_nat_0_r : \forall n, true = beq_nat 0 \ n \rightarrow 0 = n. Proof. Admitted.
```

Exercise: 3 stars (apply_exercise2) In the following proof opening, notice that we don't introduce m before performing induction. This leaves it general, so that the IH doesn't specify a particular m, but lets us pick. Finish the proof.

```
Theorem beq_nat_sym : \forall (n \ m : nat), beq_nat n \ m = beq_nat m \ n.

Proof.

intros n. induction n as [\mid n'].

Admitted.
```

Exercise: 3 stars (beq_nat_sym_informal) Provide an informal proof of this lemma that corresponds to your formal proof above:

```
Theorem: For any nats n m, beq_nat n m = beq_nat m n.
Proof: \square
```

5.5.5 Using Tactics on Hypotheses

By default, most tactics work on the goal formula and leave the context unchanged. However, most tactics also have a variant that performs a similar operation on a statement in the context.

For example, the tactic simpline H performs simplification in the hypothesis named H in the context.

```
Theorem S_inj : \forall (n \ m : nat) \ (b : bool), beq_nat (S \ n) \ (S \ m) = b \rightarrow beq_nat n \ m = b.

Proof.
```

intros $n \ m \ b \ H$. simpl in H. apply H. Qed.

Similarly, the tactic apply L in H matches some conditional statement L (of the form $L1 \to L2$, say) against a hypothesis H in the context. However, unlike ordinary apply (which rewrites a goal matching L2 into a subgoal L1), apply L in H matches H against L1 and, if successful, replaces it with L2.

In other words, apply L in H gives us a form of "forward reasoning" – from $L1 \to L2$ and a hypothesis matching L1, it gives us a hypothesis matching L2. By contrast, apply L is "backward reasoning" – it says that if we know $L1 \to L2$ and we are trying to prove L2, it suffices to prove L1.

Here is a variant of a proof from above, using forward reasoning throughout instead of backward reasoning.

```
Theorem silly3': \forall (n: nat), (beq_nat n = 5 = true \rightarrow beq_nat (S(S(n))) = true) \rightarrow true = beq_nat (S(S(n))) = true = beq_nat (S(S(S(n)))) = true = true = beq_nat (S(S(S(S(S(n))))) = true = true
```

```
Proof. intros n eq H. symmetry in H. apply eq in H. symmetry in H. apply H. Qed.
```

Forward reasoning starts from what is *given* (premises, previously proven theorems) and iteratively draws conclusions from them until the goal is reached. Backward reasoning starts from the *goal*, and iteratively reasons about what would imply the goal, until premises or previously proven theorems are reached. If you've seen informal proofs before (for example, in a math or computer science class), they probably used forward reasoning. In general, Coq tends to favor backward reasoning, but in some situations the forward style can be easier to use or to think about.

Exercise: 3 stars, recommended (plus_n_n_injective) You can practice using the "in" variants in this exercise.

```
Theorem plus_n_n_injective : \forall n \ m, n+n=m+m \rightarrow n=m.

Proof.

intros n. induction n as [\mid n'].

Admitted.
```

5.5.6 Using destruct on Compound Expressions

We have seen many examples where the destruct tactic is used to perform case analysis of the value of some variable. But sometimes we need to reason by cases on the result of some expression. We can also do this with destruct.

Here are some examples:

```
Definition sillyfun (n : nat) : bool :=
   if beq_nat n 3 then false
   else if beq_nat n 5 then false
   else false.

Theorem sillyfun_false : ∀ (n : nat),
   sillyfun n = false.

Proof.
   intros n. unfold sillyfun.
   destruct (beq_nat n 3).
        Case "beq_nat n 3 = true". reflexivity.
        Case "beq_nat n 3 = false". destruct (beq_nat n 5).
        SCase "beq_nat n 5 = true". reflexivity.
        SCase "beq_nat n 5 = false". reflexivity.
        Qed.
```

After unfolding silly fun in the above proof, we find that we are stuck on if $(beq_nat \ n)$

3) then ... else Well, either n is equal to 3 or it isn't, so we use destruct (beq_nat n

3) to let us reason about the two cases.

Exercise: 1 star (override_shadow) Theorem override_shadow : $\forall \{X: \texttt{Type}\} \ x1 \ x2 \ k1 \ k2 \ (f: \texttt{nat} \rightarrow X),$ (override (override $f \ k1 \ x2) \ k1 \ x1) \ k2 = (\mathsf{override} \ f \ k1 \ x1) \ k2.$ Proof.

Admitted.

Exercise: 3 stars, recommended (combine_split)

Exercise: 3 stars, optional (split_combine) Thought exercise: We have just proven that for all lists of pairs, *combine* is the inverse of split. How would you state the theorem showing that split is the inverse of *combine*?

Hint: what property do you need of l1 and l2 for split combine l1 l2 = (l1,l2) to be true?

State this theorem in Coq, and prove it. (Be sure to leave your induction hypothesis general by not doing intros on more things than necessary.)

5.5.7 The remember Tactic

(Note: the *remember* tactic is not strictly needed until a bit later, so if necessary this section can be skipped and returned to when needed.)

We have seen how the **destruct** tactic can be used to perform case analysis of the results of arbitrary computations. If e is an expression whose type is some inductively defined type T, then, for each constructor c of T, **destruct** e generates a subgoal in which all occurrences of e (in the goal and in the context) are replaced by c.

Sometimes, however, this substitution process loses information that we need in order to complete the proof. For example, suppose we define a function *sillyfun1* like this:

```
Definition sillyfun1 (n : nat) : bool :=  if beq_nat n \ 3 then true else if beq_nat n \ 5 then true else false.
```

And suppose that we want to convince Coq of the rather obvious observation that sil-lyfun1 n yields true only when n is odd. By analogy with the proofs we did with sillyfun above, it is natural to start the proof like this:

```
Theorem sillyfun1_odd_FAILED : \forall (n : nat), sillyfun1 n = true \rightarrow
```

```
oddb n = true.
Proof.
intros n eq. unfold sillyfun1 in eq.
destruct (beq_nat n 3).
Admitted.
```

We get stuck at this point because the context does not contain enough information to prove the goal! The problem is that the substitution performed by **destruct** is too brutal – it threw away every occurrence of $beq_nat \ n \ 3$, but we need to keep at least one of these because we need to be able to reason that since, in this branch of the case analysis, $beq_nat \ n \ 3 = true$, it must be that n = 3, from which it follows that n is odd.

What we would really like is not to use **destruct** directly on $beq_nat \ n \ 3$ and substitute away all occurrences of this expression, but rather to use **destruct** on something else that is equal to $beq_nat \ n \ 3$. For example, if we had a variable that we knew was equal to $beq_nat \ n \ 3$, we could **destruct** this variable instead.

The remember tactic allows us to introduce such a variable.

```
Theorem sillyfun1_odd : \forall (n : nat),
     sillyfun1 n = \text{true} \rightarrow
     oddb n = \text{true}.
Proof.
  intros n eq. unfold sillyfun1 in eq.
   remember (beq_nat n 3) as e3.
   destruct e3.
     Case "e3 = true". apply beq_nat_eq in Hege3.
       rewrite \rightarrow Hege3. reflexivity.
     Case "e3 = false".
       remember (beq_nat n 5) as e5. destruct e5.
         SCase "e5 = true".
           apply beq_nat_eq in Hege5.
           rewrite \rightarrow Hege 5. reflexivity.
         SCase "e5 = false". inversion eq. Qed.
nat \rightarrow X),
  f k1 = x1 \rightarrow
  (override f k1 x1) k2 = f k2.
Proof.
   Admitted.
```

Exercise: 3 stars, optional (filter_exercise) This one is a bit challenging. Be sure your initial intros go only up through the parameter on which you want to do induction!

```
Theorem filter_exercise : \forall (X : \mathsf{Type}) \ (test : X \to \mathbf{bool}) (x : X) \ (l \ lf : \mathsf{list} \ X), filter test \ l = x :: lf \to test \ x = \mathsf{true}. Proof.

Admitted.
```

5.5.8 The apply ... with ... Tactic

The following silly example uses two rewrites in a row to get from [a,b] to [e,f].

```
Example trans_eq_example : \forall (a b c d e f : nat), [a,b] = [c,d] \rightarrow [c,d] = [e,f] \rightarrow [a,b] = [e,f]. Proof. intros a b c d e f eq1 eq2. rewrite \rightarrow eq1. rewrite \rightarrow eq2. reflexivity. Qed.
```

Since this is a common pattern, we might abstract it out as a lemma recording once and for all the fact that equality is transitive.

```
Theorem trans_eq : \forall {X:Type} (n \ m \ o : X), n = m \rightarrow m = o \rightarrow n = o. Proof. intros X \ n \ m \ o \ eq1 \ eq2. rewrite \rightarrow \ eq1. rewrite \rightarrow \ eq2. reflexivity. Qed.
```

Now, we should be able to use *trans_eq* to prove the above example. However, to do this we need a slight refinement of the apply tactic.

```
Example trans_eq_example': \forall (a b c d e f: \mathsf{nat}),  [a,b] = [c,d] \to \\ [c,d] = [e,f] \to \\ [a,b] = [e,f].  Proof.  \mathsf{intros} \ a \ b \ c \ d \ e \ f \ eq1 \ eq2. \\ \mathsf{apply} \ \mathsf{trans\_eq} \ \mathsf{with} \ (m\!:=\![c,d]). \ \mathsf{apply} \ eq1. \ \mathsf{apply} \ eq2. \ \mathsf{Qed}.
```

Actually, we usually don't have to include the name m in the with clause; Coq is often smart enough to figure out which instantiation we're giving. We could instead write: apply trans_eq with c,d.

```
Exercise: 3 stars, recommended (apply_exercises) Example trans_eq_exercise: \forall (n \ m \ o \ p : nat),
m = (minustwo \ o) \rightarrow
```

```
(n + p) = m \rightarrow
       (n + p) = (minustwo o).
Proof.
    Admitted.
Theorem beq_nat_trans : \forall n \ m \ p,
  true = beq_nat n m \rightarrow
  true = beq_nat m p \rightarrow
  true = beq_nat n p.
Proof.
    Admitted.
Theorem override_permute : \forall \{X: \mathsf{Type}\} \ x1 \ x2 \ k1 \ k2 \ k3 \ (f: \mathsf{nat} \rightarrow X),
   false = beg_nat k2 \ k1 \rightarrow
   (override (override f \ k2 \ x2) \ k1 \ x1) \ k3 = (override (override f \ k1 \ x1) \ k2 \ x2) \ k3.
Proof.
    Admitted.
```

5.6 Review

We've now seen a bunch of Coq's fundamental tactics – enough to do pretty much everything we'll want for a while. We'll introduce one or two more as we go along through the next few lectures, and later in the course we'll introduce some more powerful *automation* tactics that make Coq do more of the low-level work in many cases. But basically we've got what we need to get work done.

Here are the ones we've seen:

- intros: move hypotheses/variables from goal to context
- reflexivity: finish the proof (when the goal looks like e = e)
- apply: prove goal using a hypothesis, lemma, or constructor
- apply... in *H*: apply a hypothesis, lemma, or constructor to a hypothesis in the context (forward reasoning)
- apply... with...: explicitly specify values for variables that cannot be determined by pattern matching
- simpl: simplify computations in the goal
- simpl in H: ... or a hypothesis
- rewrite: use an equality hypothesis (or lemma) to rewrite the goal

- rewrite ... in H: ... or a hypothesis
- symmetry: changes a goal of the form t=u into u=t
- symmetry in H: changes a hypothesis of the form t=u into u=t
- unfold: replace a defined constant by its right-hand side in the goal
- unfold... in H: ... or a hypothesis
- destruct... as...: case analysis on values of inductively defined types
- induction... as...: induction on values of inductively defined types
- inversion: reason by injectivity and distinctness of constructors
- remember (e) as x: give a name (x) to an expression (e) so that we can destruct x without "losing" e
- assert (e) as H: introduce a "local lemma" e and call it H

5.7 Additional Exercises

Exercise: 2 stars, optional (fold_length) Many common functions on lists can be implemented in terms of fold. For example, here is an alternate definition of *length*:

```
Definition fold_length \{X: \mathsf{Type}\}\ (l: \mathsf{list}\ X): \mathsf{nat} := \mathsf{fold}\ (\mathsf{fun}\ \_\ n \Rightarrow \mathsf{S}\ n)\ l\ 0.
Example \mathsf{test\_fold\_length1}: \mathsf{fold\_length}\ [4,7,0] = 3.
Proof. \mathsf{reflexivity}. \ \mathsf{Qed}.
Prove the correctness of \mathsf{fold\_length}.
Theorem \mathsf{fold\_length\_correct}: \ \forall\ X\ (l: \mathsf{list}\ X), \ \mathsf{fold\_length}\ l = \mathsf{length}\ l.
\mathsf{Admitted}.
```

Exercise: 3 stars, recommended (fold_map) We can also define map in terms of fold. Finish fold_map below.

```
Definition fold_map \{X \ Y : \mathsf{Type}\}\ (f: X \to Y)\ (l: \mathsf{list}\ X) : \mathsf{list}\ Y := \mathsf{admit}.
```

Write down a theorem in Coq stating that fold_map is correct, and prove it.

Module MUMBLEBAZ.

Exercise: 2 stars, optional (mumble_grumble) Consider the following two inductively defined types.

```
Inductive mumble: Type :=
   a: mumble
   b : mumble \rightarrow nat \rightarrow mumble
  c: mumble.
Inductive grumble (X:Type): Type :=
  | d : mumble \rightarrow grumble X
  \mid e : X \rightarrow grumble X.
   Which of the following are well-typed elements of grumble X for some type X?
   • d (b a 5)
   • d mumble (b a 5)
   • d bool (b a 5)
   • e bool true
   • e mumble (b c 0)
   • e bool (b c 0)
   • c
Exercise: 2 stars, optional (baz_num_elts) Consider the following inductive defini-
tion:
Inductive baz : Type :=
   | x : baz \rightarrow baz
   \mid y : baz \rightarrow bool \rightarrow baz.
   How many elements does the type baz have? \square
End MUMBLEBAZ.
Exercise: 4 stars, recommended (forall_exists_challenge) Challenge problem: De-
```

Exercise: 4 stars, recommended (forall_exists_challenge) Challenge problem: Define two recursive Fixpoints, forallb and existsb. The first checks whether every element in a list satisfies a given predicate: forallb oddb 1,3,5,7,9 = true

```
for all b neg b false, false = true for all b even b 0,2,4,5 = false
```

for allb (beq_nat 5) \square = true The function *existsb* checks whether there exists an element in the list that satisfies a given predicate: existsb (beq_nat 5) 0,2,3,6 = false

existsb (andb true) true, true, false = true

existsb oddb $1,0,0,0,0,3 = \text{true}$
exists \Box even \Box = false Next, create a nonrecursive Definition, exists b', using for all b
and $negb$.
Prove that <i>existsb</i> ' and <i>existsb</i> have the same behavior.
П
Exercise: 2 stars, optional (index_informal) Recall the definition of the index func-
tion: Fixpoint index $\{X: Type\}$ $(n: nat)$ $(l: list X): option X:= match\ l with \ \square =>$
None \mid a :: \mid ' => if beq_nat n O then Some a else index (pred n) \mid ' end. Write an informal
proof of the following theorem: for all X n l, length l = n -> @index X (S n) l = None. \Box

Chapter 6

Library Gen

6.1 Gen: Generalizing Induction Hypotheses

Require Export Poly.

In the previous chapter, we noticed the importance of controlling the exact form of the induction hypothesis when carrying out inductive proofs in Coq. In particular, we need to be careful about which of the assumptions we move (using intros) from the goal to the context before invoking the induction tactic. In this short chapter, we consider this point in a little more depth and introduce one new tactic, called generalize dependent, that is sometimes useful in helping massage the induction hypothesis into the required form.

First, let's review the basic issue. Suppose we want to show that the double function is injective – i.e., that it always maps different arguments to different results. The way we start this proof is a little bit delicate: if we begin it with intros n. induction n.]] all is well. But if we begin it with intros n m. induction n. we get stuck in the middle of the inductive case...

```
Theorem double_injective_FAILED: \forall \ n \ m, double n = double m \rightarrow n = m.

Proof.

intros n m. induction n as [|\ n'].

Case "n = O". simpl. intros eq. destruct m as [|\ m'].

SCase "m = O". reflexivity.

SCase "m = S m'". inversion eq.

Case "n = S n'". intros eq. destruct m as [|\ m'].

SCase "m = O". inversion eq.

SCase "m = O". inversion eq.

SCase "m = S m'".

assert (n' = m') as H.

SSCase "Proof of assertion".

Admitted.
```

What went wrong?

The problem is that, at the point we invoke the induction hypothesis, we have already introduced m into the context intuitively, we have told Coq, "Let's consider some particular n and m..." and we now have to prove that, if double n = double m for this particular n and m, then n = m.

The next tactic, induction n says to Coq: We are going to show the goal by induction on n. That is, we are going to prove that the proposition

• $P \ n =$ "if double n = double m, then n = m"

holds for all n by showing

- P O (i.e., "if double O = double m then O = m")
- $P \ n \to P \ (S \ n)$ (i.e., "if double $n = double \ m$ then n = m" implies "if double $(S \ n) = double \ m$ then $S \ n = m$ ").

If we look closely at the second statement, it is saying something rather strange: it says that, for a particular m, if we know

• "if double n = double m then n = m"

then we can prove

• "if double $(S \ n) = double \ m$ then $S \ n = m$ ".

To see why this is strange, let's think of a particular m – say, 5. The statement is then saying that, if we can prove

• Q = "if double n = 10 then n = 5"

then we can prove

• R = "if double $(S \ n) = 10$ then $S \ n = 5$ ".

But knowing Q doesn't give us any help with proving R! (If we tried to prove R from Q, we would say something like "Suppose double (S n) = 10..." but then we'd be stuck: knowing that double (S n) is 10 tells us nothing about whether double n is 10, so Q is useless at this point.)

To summarize: Trying to carry out this proof by induction on n when m is already in the context doesn't work because we are trying to prove a relation involving *every* n but just a $single \ m$.

The good proof of $double_injective$ leaves m in the goal statement at the point where the induction tactic is invoked on n:

```
Theorem double_injective': \forall n m,
     double n = double m \rightarrow
     n = m.
Proof.
  intros n. induction n as [\mid n'].
  Case "n = O". simpl. intros m eq. destruct m as [|m'|].
    SCase "m = O". reflexivity.
    SCase "m = S m'.". inversion eq.
  Case "n = S n".
    intros m eq.
    destruct m as [|m'|].
                                          SCase "m = S m'".
    SCase "m = O". inversion eq.
      assert (n' = m') as H.
      SSCase "Proof of assertion". apply IHn'.
         inversion eq. reflexivity.
      rewrite \rightarrow H. reflexivity. Qed.
```

What this teaches us is that we need to be careful about using induction to try to prove something too specific: If we're proving a property of n and m by induction on n, we may need to leave m generic.

However, this strategy doesn't always apply directly; sometimes a little rearrangement is needed. Suppose, for example, that we had decided we wanted to prove $double_injective$ by induction on m instead of n.

```
Theorem double_injective_take2_FAILED: \forall n \ m, double n = double m \rightarrow n = m.

Proof.

intros n m. induction m as [\mid m'].

Case "m = O". simpl. intros eq. destruct n as [\mid n'].

SCase "n = O". reflexivity.

SCase "n = S n". inversion eq.

Case "n = S n". intros eq. destruct n as [\mid n'].

SCase "n = O". inversion eq.

SCase "n = O". inversion eq.

SCase "n = S n".

assert (n' = m') as H.

SSCase "Proof of assertion".

Admitted.
```

The problem is that, to do induction on m, we must first introduce n. (If we simply say induction m without introducing anything first, Coq will automatically introduce n for us!) What can we do about this? One possibility is to rewrite the statement of the lemma so

that m is quantified before n. This will work, but it's not nice: We don't want to have to mangle the statements of lemmas to fit the needs of a particular strategy for proving them – we want to state them in the most clear and natural way.

What we can do instead is to first introduce all the quantified variables and then *regeneralize* one or more of them, taking them out of the context and putting them back at the beginning of the goal. The generalize dependent tactic does this.

```
Theorem double_injective_take2 : \forall n m.
     double n = double m \rightarrow
     n = m.
Proof.
  intros n m.
  generalize dependent n.
  induction m as [|m'|].
  Case "m = O". simpl. intros n eq. destruct n as [n'].
    SCase "n = O". reflexivity.
    SCase "n = S n'.". inversion eq.
  Case "m = S m'". intros n eq. destruct n as [n'].
    SCase "n = O". inversion eq.
    SCase "n = S n'".
      assert (n' = m') as H.
      SSCase "Proof of assertion".
         apply IHm'. inversion eq. reflexivity.
      rewrite \rightarrow H. reflexivity. Qed.
```

Let's look at an informal proof of this theorem. Note that the proposition we prove by induction leaves n quantified, corresponding to the use of generalize dependent in our formal proof.

Theorem: For any nats n and m, if double n = double m, then n = m.

Proof: Let m be a nat. We prove by induction on m that, for any n, if $double\ n = double\ m$ then n = m.

• First, suppose m = 0, and suppose n is a number such that double n = double m. We must show that n = 0.

Since m = 0, by the definition of double we have double n = 0. There are two cases to consider for n. If n = 0 we are done, since this is what we wanted to show. Otherwise, if n = S n' for some n', we derive a contradiction: by the definition of double we would have n = S (S (double n')), but this contradicts the assumption that double n = 0.

• Otherwise, suppose m = S m' and that n is again a number such that double n = double m. We must show that n = S m', with the induction hypothesis that for every number s, if double s = double m' then s = m'.

By the fact that m = S m' and the definition of double, we have double n = S (S (double m')). There are two cases to consider for n.

If n=0, then by definition double n=0, a contradiction. Thus, we may assume that n = S n' for some n', and again by the definition of double we have $S(S(double\ n'))$ $= S(S(double\ m')),$ which implies by inversion that double $n' = double\ m'.$ Instantiating the induction hypothesis with n' thus allows us to conclude that n' =m', and it follows immediately that S n' = S m'. Since S n' = n and S m' = m, this is just what we wanted to show. \square Exercise: 3 stars, recommended (gen_dep_practice) Carry out this proof by induction on m. Theorem plus_n_n_injective_take2 : $\forall n m$, $n + n = m + m \rightarrow$ n = m. Proof. Admitted. Now prove this by induction on l. Theorem index_after_last: $\forall (n : nat) (X : Type) (l : list X),$ length $l = n \rightarrow$ index (S n) l = None. Proof. Admitted. Exercise: 3 stars, optional (index_after_last_informal) Write an informal proof corresponding to your Coq proof of index_after_last: Theorem: For all sets X, lists l: list X, and numbers n, if length l=n then index (S n)l = None. $Proof: \square$ Exercise: 3 stars (gen_dep_practice_opt) Prove this by induction on l. Theorem length_snoc''' : $\forall (n : nat) (X : Type)$ (v:X) (l: list X), length $l = n \rightarrow$ length (snoc l v) = S n. Proof. Admitted.

Exercise: 3 stars (app_length_cons) Prove this by induction on l1, without using app_length.

Theorem app_length_cons : $\forall (X : Type) (l1 \ l2 : list \ X)$

Exercise: 4 stars, optional (app_length_twice) Prove this by induction on *l*, without using app_length.

Chapter 7

Library Prop

7.1 Prop: Propositions and Evidence

Require Export Poly.

In previous chapters, we have seen many examples of factual claims (*propositions*) and ways of presenting evidence of their truth (*proofs*). In particular, we have worked extensively with *equality propositions* of the form e1 = e2, with implications $(P \to Q)$, and with quantified propositions $(\forall x, P)$.

In this chapter we take a deeper look at the way propositions are expressed in Coq and at the structure of the logical evidence that we construct when we carry out proofs.

Some of the concepts in this chapter may seem a bit abstract on a first encounter. We've included a *lot* of exercises, most of which should be quite approachable even if you're still working on understanding the details of the text. Try to work as many of them as you can, especially the one-starred exercises.

7.2 Inductively Defined Propositions

As a running example for the first part of the chapter, let's consider a simple property of natural numbers, and let's say that the numbers possessing this property are "beautiful."

Informally, a number is *beautiful* if it is 0, 3, 5, or the sum of two beautiful numbers. More pedantically, we can define beautiful numbers by giving four rules:

- Rule $b_-\theta$: The number 0 is beautiful.
- Rule $b_{-}3$: The number 3 is beautiful.
- Rule b_-5 : The number 5 is beautiful.
- Rule b_sum : If n and m are both beautiful, then so is their sum.

We will see many definitions like this one during the rest of the course, and for purposes of informal discussions, it is helpful to have a lightweight notation that makes them easy to read and write. *Inference rules* are one such notation:

(b_0) beautiful 0

(b_3) beautiful 3

(b_5) beautiful 5
beautiful n beautiful m

(b_sum) beautiful (n+m)

Each of the textual rules above is reformatted here as an inference rule; the intended reading is that, if the *premises* above the line all hold, then the *conclusion* below the line follows. For example, the rule b_sum says that, if n and m are both beautiful numbers, then it follows that n+m is beautiful too. The rules with no premises above the line are called *axioms*.

These rules define the property beautiful. That is, if we want to convince someone that some particular number is beautiful, our argument must be based on these rules. For a simple example, suppose we claim that the number 5 is beautiful. To support this claim, we just need to point out that rule b_-5 says it is. Or, if we want to claim that 8 is beautiful, we can support our claim by first observing that 3 and 5 are both beautiful (by rules b_-3 and b_-5) and then pointing out that their sum, 8, is therefore beautiful by rule b_-sum . This argument can be expressed graphically with the following proof tree:

 $(b_{-}3)$ — $(b_{-}5)$ beautiful 3 beautiful 5

(b_sum) beautiful 8 Of course, there are other ways of using these rules to argue that 8 is beautiful – for instance:

 (b_-5) ——— (b_-3) beautiful 5 beautiful 3

(b_sum) beautiful 8

Exercise: 1 star (varieties_of_beauty) How many different ways are there to show that 8 is beautiful?

In Coq, we can express the definition of beautiful as follows:

Inductive **beautiful**: $nat \rightarrow Prop :=$

b_0: beautiful 0 | b_3: beautiful 3 | b_5: beautiful 5

```
| b_sum : \forall n \ m, beautiful n \rightarrow beautiful m \rightarrow beautiful (n+m).
```

The first line declares that beautiful is a proposition – or, more formally, a family of propositions "indexed by" natural numbers. (For each number n, the claim that "n is beautiful" is a proposition.) Such a family of propositions is often called a property of numbers.

Each of the remaining lines embodies one of the rules for beautiful numbers.

We can use Coq's tactic scripting facility to assemble proofs that particular numbers are beautiful.

```
Theorem three_is_beautiful: beautiful 3. Proof.

apply b_3. Qed.

Theorem eight_is_beautiful: beautiful 8. Proof.

apply b_sum with (n:=3) (m:=5).

apply b_3.

apply b_5. Qed.
```

7.3 Proof Objects

Look again at the formal definition of the *beautiful* property. The opening keyword, Inductive, has been used up to this point to declare new types of *data*, such as numbers and lists. Does this interpretation also make sense for the Inductive definition of *beautiful*? That is, can we view evidence of beauty as some kind of data structure? Yes, we can!

The trick is to introduce an alternative pronunciation of ":". Instead of "has type," we can also say "is a proof of." For example, the second line in the definition of beautiful declares that $b_-\theta$: beautiful 0. Instead of " $b_-\theta$ has type beautiful 0," we can say that " $b_-\theta$ is a proof of beautiful 0." Similarly for $b_-\beta$ and $b_-\delta$.

This pun between ":" as "has type" and : as "is a proof of" is called the *Curry-Howard correspondence* (or sometimes *Curry-Howard isomorphism*). It proposes a deep connection between the world of logic and the world of computation.

```
propositions ~ types
evidence ~ data
```

Many useful things follow from this connection. To begin with, it gives us a natural interpretation of the b_sum constructor:

b_sum: forall n m, beautiful n -> beautiful m -> beautiful (n+m). If we read: as "has type," this says that b_sum is a data constructor that takes four arguments: two numbers, n and m, and two values of type beautiful n and beautiful m. That is, b_sum can be viewed as a function that, given evidence for the propositions beautiful n and beautiful m, gives us evidence for the proposition that beautiful n.

In view of this, we might wonder whether we can write an expression of type beautiful 8 by applying b_sum to appropriate arguments. Indeed, we can:

```
Check (b_sum 3.5 b_{-}3 b_{-}5).
```

The expression b_sum 3 5 b_3 b_5 can be thought of as instantiating the parameterized constructor b_sum with the specific arguments 3 5 and the corresponding proof objects for its premises beautiful 3 and beautiful 5 (Coq is smart enough to figure out that 3+5=8). Alternatively, we can think of b_sum as a primitive "evidence constructor" that, when applied to two particular numbers, wants to be further applied to evidence that those two numbers are beautiful; its type, $[\forall n \ m, beautiful \ n \rightarrow beautiful \ m \rightarrow beautiful \ (n+m), expresses this functionality, in the same way that the polymorphic type <math>[\forall X, list \ X]$ in the previous chapter expressed the fact that the constructor [nil] can be thought of as a function from types to empty lists with elements of that type.

This gives us an alternative way to write the proof that 8 is beautiful:

```
Theorem eight_is_beautiful': beautiful 8. Proof.
apply (b_sum 3 5 b_3 b_5).
Qed.
```

Notice that we're using apply here in a new way: instead of just supplying the *name* of a hypothesis or previously proved theorem whose type matches the current goal, we are supplying an *expression* that directly builds evidence with the required type.

7.3.1 Proof Scripts and Proof Objects

These proof objects lie at the core of how Coq operates.

When Coq is following a proof script, what is happening internally is that it is gradually constructing a proof object – a term whose type is the proposition being proved. The tactics between the Proof command and the Qed instruct Coq how to build up a term of the required type. To see this process in action, let's use the Show Proof command to display the current state of the proof tree at various points in the following tactic proof.

```
Theorem eight_is_beautiful'': beautiful 8.

Proof.

apply b_sum with (n:=3) (m:=5).

Show Proof.

apply b_3.

Show Proof.

apply b_5.

Show Proof.

Qed.
```

At any given moment, Coq has constructed a term with some "holes" (indicated by ?1, ?2, and so on), and it knows what type of evidence is needed at each hole. In the Show Proof output, lines of the form $?1 \rightarrow beautiful\ n$ record these requirements. (The \rightarrow here

has nothing to do with either implication or function types – it is just an unfortunate choice of concrete syntax for the output!)

Each of the holes corresponds to a subgoal, and the proof is finished when there are no more subgoals. At this point, the **Theorem** command gives a name to the evidence we've built and stores it in the global context.

Tactic proofs are useful and convenient because they avoid building proof trees by hand, but they are not essential: in principle, we can always construct the required evidence by hand. Indeed, we don't even need the **Theorem** command: we can use **Definition** instead, to directly give a global name to a piece of evidence.

```
Definition eight_is_beautiful''': beautiful 8:= b_sum 3 5 b_3 b_5.
```

All these different ways of building the proof lead to exactly the same evidence being saved in the global environment.

```
Print eight_is_beautiful.
Print eight_is_beautiful'.
Print eight_is_beautiful''.
Print eight_is_beautiful'''.
```

Exercise: 1 star (six_is_beautiful) Give a tactic proof and a proof object showing that 6 is beautiful.

```
Theorem six_is_beautiful : beautiful 6. Proof. Admitted. Definition six_is_beautiful' : beautiful 6 := admit. \Box
```

Exercise: 1 star (nine_is_beautiful) Give a tactic proof and a proof object showing that 9 is beautiful.

```
Theorem nine_is_beautiful:

beautiful 9.

Proof.

Admitted.

Definition nine_is_beautiful': beautiful 9:=

admit.
```

7.3.2 Implications and Functions

If we want to substantiate the claim that $P \to Q$, what sort of proof object should count as evidence?

We've seen one case above: the b_sum constructor, which is *primitive* evidence for an implication proposition – it is part of the very meaning of the word "beautiful" in this context. But what about other implications that we might want to prove?

For example, consider this statement:

```
Theorem b_plus3: \forall n, beautiful n \to \text{beautiful } (3+n). Proof.

intros n H.

apply b_sum.

apply b_3.

apply H.

Qed.
```

What is the proof object corresponding to $b_{-}plus3$?

We've made a notational pun between \rightarrow as implication and \rightarrow as the type of functions. If we take this pun seriously, then what we're looking for is an expression whose type is $\forall n$, beautiful $n \rightarrow beautiful$ (3+n) – that is, a function that takes two arguments (one number and a piece of evidence) and returns a piece of evidence! Here it is:

```
Definition b_plus3' : \forall n, beautiful n \rightarrow beautiful (3+n) :=  fun n \Rightarrow fun H : beautiful n \Rightarrow b_sum 3 n b_3 H. Check b_plus3'.
```

Recall that fun $n \Rightarrow blah$ means "the function that, given n, yields blah." Another equivalent way to write this definition is:

```
Definition b_plus3'' (n: nat) (H: beautiful\ n): beautiful\ (3+n):= b_sum\ 3\ n\ b_3\ H. Check b_plus3''.
```

Exercise: 2 stars (b_times2) Theorem b_times2: $\forall n$, beautiful $n \to \text{beautiful } (2 \times n)$. Proof.

Admitted.

Exercise: 3 stars, optional (b_times2') Write a proof object corresponding to b_times2 above

```
Definition b_times2': \forall n, beautiful n \rightarrow beautiful (2 \times n) := admit.
```

```
Exercise: 2 stars (b_timesm) Theorem b_timesm: \forall \ n \ m, beautiful n \to \text{beautiful} (m \times n). Proof.

Admitted.
```

7.3.3 Induction Over Proof Objects

Since we use the keyword Induction to define primitive propositions together with their evidence, we might wonder whether there are some sort of induction principles associated with these definitions. Indeed there are, and in this section we'll take a look at how they can be used.

Besides constructing evidence that numbers are beautiful, we can also reason about such evidence. The fact that we introduced beautiful with an Inductive declaration tells us not only that the constructors b_-0 , b_-3 , b_-5 and b_-sum are ways to build evidence, but also that these two constructors are the only ways to build evidence that numbers are beautiful.

In other words, if someone gives us evidence E justifying the assertion beautiful n, then we know that E can only have one of four forms: either E is b_-0 (and n is O) or E is b_-3 (and n is 3), or E is b_-5 (and n is 5), or E is $b_-sum\ n1\ n2\ E1\ E2$ (and n is (n1+n2), and E1 is evidence that n1 is beautiful and E2 is evidence that n2 is beautiful).

Thus, it makes sense to use the tactics that we have already seen for inductively defined data to reason instead about inductively defined evidence.

Let's introduce a new property of numbers to help illustrate the role of induction.

```
Inductive gorgeous : \operatorname{nat} \to \operatorname{Prop} := g_0 : \operatorname{gorgeous} 0
| g_{\operatorname{plus}} : \forall n, \operatorname{gorgeous} n \to \operatorname{gorgeous} (3+n)
| g_{\operatorname{plus}} : \forall n, \operatorname{gorgeous} n \to \operatorname{gorgeous} (5+n).
```

Exercise: 1 star (gorgeous_tree) Write out the definition of gorgeous numbers using the *inference rule* notation.

It seems intuitively obvious that, although *gorgeous* and *beautiful* are presented using slightly different rules, they are actually the same property in the sense that they are true of the same numbers. Indeed, we can prove this.

```
Theorem gorgeous_beautiful: \forall n, gorgeous n \rightarrow beautiful n.

Proof.

intros.

induction H as [|n'|n'].

Case "g_0".

apply b_0.

Case "g_plus3".
```

```
apply b_sum. apply b_3.
        apply IHqorqeous.
   Case "g_plus5".
        apply b_sum. apply b_5. apply IHqorqeous.
Qed.
   Let's see what happens if we try to prove this by induction on n instead of induction on
the evidence H.
Theorem gorgeous_beautiful_FAILED : \forall n,
  gorgeous n \to \text{beautiful } n.
Proof.
   intros. induction n as [\mid n'].
   Case "n = 0". apply b_0.
   Case "n = S n". Admitted.
Exercise: 1 star (gorgeous_plus13) Theorem gorgeous_plus13: \forall n,
  gorgeous n \to \text{gorgeous } (13+n).
Proof.
   Admitted.
Exercise: 2 stars (gorgeous_plus13_po): Give the proof object for theorem gor-
geous_plus13 above.
Definition gorgeous_plus13_po: \forall n, gorgeous n \to \text{gorgeous} (13+n):=
   admit.
   Exercise: 2 stars (gorgeous_sum) Theorem gorgeous_sum : \forall n m,
  gorgeous n \to \text{gorgeous } m \to \text{gorgeous } (n + m).
Proof.
   Admitted.
   Exercise: 3 stars (beautiful_gorgeous) Theorem beautiful_gorgeous: \forall n, beautiful
n \to \mathbf{gorgeous} \ n.
Proof.
   Admitted.
```

Lemma helper_g_times2 : $\forall x y z, x + (z + y) = z + x + y$.

```
Proof. Admitted. Theorem g_times2: \forall n, gorgeous n \to \text{gorgeous}\ (2 \times n). Proof. intros n H. simpl. induction H. Admitted.
```

7.3.4 Evenness

In chapter Basics we defined a $function\ evenb$ that tests a number for evenness, yielding true if so. This gives us an obvious way of defining the concept of evenness:

```
Definition even (n:nat): Prop := evenb n = true.
```

That is, we can define "n is even" to mean "the function *evenb* returns *true* when applied to n."

Another alternative is to define the concept of evenness directly. Instead of going via the *evenb* function ("a number is even if a certain computation yields *true*"), we can say what the concept of evenness means by giving two different ways of presenting *evidence* that a number is even.

```
Inductive ev : nat \rightarrow Prop := | ev_0 : ev 0 | ev_SS : \forall n:nat, ev n \rightarrow ev (S (S n)).
```

This definition says that there are two ways to give evidence that a number m is even. First, 0 is even, and $ev_{-}\theta$ is evidence for this. Second, if m = S(S n) for some n and we can give evidence e that n is even, then m is also even, and $ev_{-}SS(n)$ e is the evidence.

Exercise: 1 star (double_even) Construct a tactic proof of the following proposition.

```
Theorem double_even : \forall n, ev (double n).

Proof.

Admitted.
```

Exercise: 4 stars, optional (double_even_pfobj) Try to predict what proof object is constructed by the above tactic proof. (Before checking your answer, you'll want to strip out any uses of Case, as these will make the proof object look a bit cluttered.) \square

Discussion: Computational vs. Inductive Definitions

We have seen that the proposition "some number is even" can be phrased in two different ways – indirectly, via a boolean testing function *evenb*, or directly, by inductively describing what constitutes evidence for evenness. These two ways of defining evenness are about equally easy to state and work with. Which we choose is basically a question of taste.

However, for many other properties of interest, the direct inductive definition is preferable, since writing a testing function may be awkward or even impossible.

One such property is beautiful. This is a perfectly sensible definition of a set of numbers, but we cannot translate its definition directly as a Coq Fixpoint (or translate it directly into a recursive function in any other programming language). We might be able to find a clever way of testing this property using a Fixpoint (indeed, it is not too hard to find one in this case), but in general this could require arbitrarily deep thinking. In fact, if the property we are interested in is uncomputable, then we cannot define it as a Fixpoint no matter how hard we try, because Coq requires that all Fixpoints correspond to terminating computations.

On the other hand, writing an inductive definition of what it means to give evidence for the property beautiful is straightforward.

7.3.5 Inverting Evidence

Besides induction, we can use the other tactics in our toolkit with evidence. For example, this proof uses destruct on evidence.

```
Theorem ev_minus2: \forall n, ev n \rightarrow ev (pred (pred n)).

Proof.

intros n E.

destruct E as [|n' E'|].

Case "E = ev_0". simpl. apply ev_0.

Case "E = ev_SS n' E'". simpl. apply E'. Qed.
```

Exercise: 1 star, optional (ev_minus2_n) What happens if we try to destruct on n instead of E? \square

Exercise: 1 star, recommended (ev__even) Here is a proof that the inductive definition of evenness implies the computational one.

```
Theorem ev__even : \forall n, ev n \to \text{even } n. Proof. intros n E. induction E as [\mid n' E']. Case "E = \text{ev}_0". unfold even. reflexivity.
```

```
\it Case "E = ev\_SS \ n' \ E'". \ unfold even. apply \it IHE'. \ Qed.
```

Could this proof also be carried out by induction on n instead of E? If not, why not?

The induction principle for inductively defined propositions does not follow quite the same form as that of inductively defined sets. For now, you can take the intuitive view that induction on evidence ev n is similar to induction on n, but restricts our attention to only those numbers for which evidence ev n could be generated. We'll look at the induction principle of ev in more depth below, to explain what's really going on.

Exercise: 1 star (l_fails) The following proof attempt will not succeed. Theorem 1: forall n, ev n. Proof. intros n. induction n. Case "O". simpl. apply ev_0. Case "S". ... Briefly explain why.

Exercise: 2 stars (ev_sum) Here's another exercise requiring induction.

```
Theorem ev_sum : \forall n \ m, ev n \to \text{ev } m \to \text{ev } (n+m). Proof. Admitted.
```

Here's another situation where we want to analyze evidence for evenness: proving that if n+2 is even, then n is. Our first idea might be to use **destruct** for this kind of case analysis:

```
Theorem SSev_ev_firsttry : \forall n, ev (S (S n)) \rightarrow ev n.

Proof.
intros n E.
destruct E as [|n'|E'].

Admitted.
```

In the first sub-goal, we've lost the information that n is 0. We could have used *remember*, but then we still need **inversion** on both cases.

```
Theorem SSev_ev_secondtry: \forall n, ev (S(S(n)) \rightarrow ev(n)).

Proof.

intros n \in E. ev(S(S(n))) as n \in E.

destruct E as [|n'(E')|].

ev(S(S(n))) as n \in E.

ev(S(S(n))) as n \in E.
```

There is a much simpler way to this: we can use inversion directly on the inductively defined proposition ev(S(S n)).

```
Theorem SSev_even : \forall n, ev (S(S(n)) \rightarrow ev(n)). Proof. intros n \in E. inversion E as [n' \in E']. apply E'. Qed.
```

This use of inversion may seem a bit mysterious at first. Until now, we've only used inversion on equality propositions, to utilize injectivity of constructors or to discriminate between different constructors. But we see here that inversion can also be applied to analyzing evidence for inductively defined propositions.

Here's how inversion works in general. Suppose the name I refers to an assumption P in the current context, where P has been defined by an Inductive declaration. Then, for each of the constructors of P, inversion I generates a subgoal in which I has been replaced by the exact, specific conditions under which this constructor could have been used to prove P. Some of these subgoals will be self-contradictory; inversion throws these away. The ones that are left represent the cases that must be proved to establish the original goal.

In this particular case, the inversion analyzed the construction ev(S(S n)), determined that this could only have been constructed using ev_-SS , and generated a new subgoal with the arguments of that constructor as new hypotheses. (It also produced an auxiliary equality, which happens to be useless here.) We'll begin exploring this more general behavior of inversion in what follows.

```
Exercise: 1 star (inversion_practice) Theorem SSSSev_even : \forall n, ev (S (S (S (S n)))) \rightarrow ev n.

Proof.

Admitted.
```

The inversion tactic can also be used to derive goals by showing the absurdity of a hypothesis.

```
Theorem even5_nonsense:
```

```
ev 5 \rightarrow 2 + 2 = 9.
Proof.
Admitted.
```

We can generally use inversion on inductive propositions. This illustrates that in general, we get one case for each possible constructor. Again, we also get some auxiliary equalities that are rewritten in the goal but not in the other hypotheses.

```
Theorem ev_minus2': \forall n,

ev n \rightarrow ev (pred (pred n)).

Proof.

intros n E. inversion E as [| n' E'].

Case "E = ev_0". simpl. apply ev_0.
```

```
Case \text{ "E} = ev\_SS \text{ n' E'"}. \text{ simpl. apply } E'. \text{ Qed.}
```

Exercise: 3 stars, recommended (ev_ev_ev) Finding the appropriate thing to do induction on is a bit tricky here:

```
Theorem ev_ev__ev : \forall n \ m, ev (n+m) \rightarrow ev n \rightarrow ev m. Proof. Admitted.
```

Exercise: 3 stars, optional (ev_plus_plus) Here's an exercise that just requires applying existing lemmas. No induction or even case analysis is needed, but some of the rewriting may be tedious. You'll want the replace tactic used for plus_swap' in Basics.v

```
Theorem ev_plus_plus : \forall n \ m \ p, ev (n+m) \rightarrow ev (n+p) \rightarrow ev (m+p). Proof.

Admitted.
```

7.4 Programming with Propositions

A proposition is a statement expressing a factual claim, like "two plus two equals four." In Coq, propositions are written as expressions of type Prop. Although we haven't mentioned it explicitly, we have already seen numerous examples.

```
Check (2 + 2 = 4).
Check (ble_nat 3 \ 2 = false).
Check (beautiful 8).
```

Both provable and unprovable claims are perfectly good propositions. Simply being a proposition is one thing; being provable is something else!

```
Check (2 + 2 = 5).
Check (beautiful 4).
```

Both 2 + 2 = 4 and 2 + 2 = 5 are legal expressions of type Prop.

We've seen one way that propositions can be used in Coq: in Theorem (and Lemma and Example) declarations.

```
Theorem plus_2_2_is_4:

2 + 2 = 4.

Proof. reflexivity. Qed.
```

But they can be used in many other ways. For example, we can give a name to a proposition using a **Definition**, just as we have given names to expressions of other sorts (numbers, functions, types, type functions, ...).

```
Definition plus_fact : Prop := 2 + 2 = 4. Check plus_fact.
```

Now we can use this name in any situation where a proposition is expected – for example, as the claim in a **Theorem** declaration.

```
Theorem plus_fact_is_true:
    plus_fact.
Proof. reflexivity. Qed.
```

There are many ways of constructing propositions. We can define a new proposition primitively using Inductive, we can form an equality proposition from two computational expressions, and we can build up a new proposition from existing ones using implication and quantification.

```
Definition strange_prop1 : Prop := (2 + 2 = 5) \rightarrow (99 + 26 = 42).
```

Also, given a proposition P with a free variable n, we can form the proposition $\forall n, P$.

```
Definition strange_prop2 :=
```

```
\forall n, (ble_nat n 17 = true) \rightarrow (ble_nat n 99 = true).
```

We can also define *parameterized propositions*, such as the property of being even.

Check even.

Check (even 4).

Check (even 3).

The type of even, $nat \rightarrow Prop$, can be pronounced in three equivalent ways: (1) "even is a function from numbers to propositions," (2) "even is a family of propositions, indexed by a number n," or (3) "even is a property of numbers."

Propositions – including parameterized propositions – are first-class citizens in Coq. For example, we can define them to take multiple arguments...

```
Definition between (n m o: nat) : Prop :=
  andb (ble_nat n o) (ble_nat o m) = true.
  ... and then partially apply them:
Definition teen : nat→Prop := between 13 19.
```

We can even pass propositions – including parameterized propositions – as arguments to functions:

```
 \begin{array}{c} {\tt Definition\ true\_for\_zero\ }(P: {\color{red}{\bf nat}} {\rightarrow} {\tt Prop}): {\tt Prop}:= \\ P\ 0. \end{array}
```

Here are two more examples of passing parameterized propositions as arguments to a function. The first takes a proposition P as argument and builds the proposition that P is

true for all natural numbers. The second takes P and builds the proposition that, if P is true for some natural number n', then it is also true by the successor of n' – i.e. that P is preserved by successor:

```
Definition true_for_all_numbers (P: \mathbf{nat} \to \mathsf{Prop}) : \mathsf{Prop} := \forall \ n, \ P \ n.
Definition preserved_by_S (P: \mathbf{nat} \to \mathsf{Prop}) : \mathsf{Prop} := \forall \ n', \ P \ n' \to P \ (\mathsf{S} \ n').
```

7.5 Induction Principles

This is a good point to pause and take a deeper look at induction principles in general.

7.5.1 Induction Principles for Inductively Defined Types

Every time we declare a new Inductive datatype, Coq automatically generates an axiom that embodies an *induction principle* for this type.

The induction principle for a type t is called $t_{-}ind$. Here is the one for natural numbers:

Check nat_ind.

The induction tactic is a straightforward wrapper that, at its core, simply performs apply $t_{-}ind$. To see this more clearly, let's experiment a little with using apply $nat_{-}ind$

apply $t_{-}ind$. To see this more clearly, let's experiment a little with using apply $nat_{-}ind$ directly, instead of the induction tactic, to carry out some proofs. Here, for example, is an alternate proof of a theorem that we saw in the Basics chapter.

```
Theorem mult_0_r': \forall n:nat, n \times 0 = 0.

Proof.

apply nat_ind.

Case "O". reflexivity.

Case "S". simpl. intros n IHn. rewrite \rightarrow IHn. reflexivity. Qed.
```

This proof is basically the same as the earlier one, but a few minor differences are worth noting. First, in the induction step of the proof (the "S" case), we have to do a little bookkeeping manually (the intros) that induction does automatically.

Second, we do not introduce n into the context before applying nat_ind – the conclusion of nat_ind is a quantified formula, and apply needs this conclusion to exactly match the shape of the goal state, including the quantifier. The induction tactic works either with a variable in the context or a quantified variable in the goal.

Third, the apply tactic automatically chooses variable names for us (in the second subgoal, here), whereas induction lets us specify (with the as... clause) what names should be used. The automatic choice is actually a little unfortunate, since it re-uses the name n for a variable that is different from the n in the original theorem. This is why the Case annotation

is just S – if we tried to write it out in the more explicit form that we've been using for most proofs, we'd have to write n = S n, which doesn't make a lot of sense! All of these conveniences make induction nicer to use in practice than applying induction principles like nat_ind directly. But it is important to realize that, modulo this little bit of bookkeeping, applying nat_ind is what we are really doing.

Exercise: 2 stars, optional (plus_one_r') Complete this proof as we did $mult_-\theta_-r'$ above, without using the induction tactic.

```
Theorem plus_one_r' : \forall n:nat,

n + 1 = S n.

Proof.

Admitted.
```

The induction principles that Coq generates for other datatypes defined with Inductive follow a similar pattern. If we define a type t with constructors c1 ... cn, Coq generates a theorem with this shape: t_ind: forall P: t-> Prop, ... case for c1 ... -> ... case for c2 ... -> ... -> ... case for cn ... -> forall n: t, P n The specific shape of each case depends on the arguments to the corresponding constructor. Before trying to write down a general rule, let's look at some more examples. First, an example where the constructors take no arguments:

```
Inductive yesno : Type :=
  | yes : yesno
  | no : yesno.
Check yesno_ind.
```

Exercise: 1 star (rgb) Write out the induction principle that Coq will generate for the following datatype. Write down your answer on paper, and then compare it with what Coq prints.

```
Inductive rgb : Type :=
  | red : rgb
  | green : rgb
  | blue : rgb.
Check rgb_ind.
```

Here's another example, this time with one of the constructors taking some arguments.

Exercise: 1 star (natlist1) Suppose we had written the above definition a little differently:

Inductive natlist1 : Type :=
 | nnil1 : natlist1
 | nsnoc1 : natlist1 → nat → natlist1.
 Now what will the induction principle look like? □

From these examples, we can extract this general rule:

- The type declaration gives several constructors; each corresponds to one clause of the induction principle.
- Each constructor c takes argument types a1...an.
- \bullet Each ai can be either t (the datatype we are defining) or some other type s.
- The corresponding case of the induction principle says (in English):
 - "for all values x1...xn of types a1...an, if P holds for each of the xs of type t, then P holds for c x1 ... xn".

Exercise: 1 star (ex_set) Here is an induction principle for an inductively defined set. ExSet_ind: forall P: ExSet -> Prop, (forall b: bool, P (con1 b)) -> (forall (n: nat) (e: ExSet), Pe -> P (con2 ne)) -> forall e: ExSet, Pe Give an Inductive definition of ExSet:

Inductive ExSet : Type :=

What about polymorphic datatypes?

The inductive definition of polymorphic lists Inductive list (X:Type): Type := | nil : list X | cons : X -> list X -> list X. is very similar to that of *natlist*. The main difference is that, here, the whole definition is *parameterized* on a set X: that is, we are defining a *family* of inductive types *list* X, one for each X. (Note that, wherever *list* appears in the body of the declaration, it is always applied to the parameter X.) The induction principle is likewise parameterized on X: list_ind : forall (X : Type) (P : list X -> Prop), P \Box -> (forall (x : X) (l : list X), P l -> P (x :: l)) -> forall l : list X, P l Note the wording here (and, accordingly, the form of *list_ind*): The *whole* induction principle is parameterized on X. That is, *list_ind* can be thought of as a polymorphic function that, when applied to a type X, gives us back an induction principle specialized to the type *list* X.

Exercise: 1 star (tree) Write out the induction principle that Coq will generate for the following datatype. Compare your answer with what Coq prints.

```
Inductive tree (X: \mathsf{Type}): \mathsf{Type} := | \mathsf{leaf}: X \to \mathsf{tree}\ X | \mathsf{node}: \mathsf{tree}\ X \to \mathsf{tree}\ X \to \mathsf{tree}\ X. Check tree_ind. \square
```

Exercise: 1 star (mytype) Find an inductive definition that gives rise to the following induction principle: mytype_ind: forall (X : Type) (P : mytype X -> Prop), (forall x : X, $P (constr1 X x)) -> (forall n : nat, <math>P (constr2 X n)) -> (forall m : mytype X, <math>P m -> forall n : nat, P (constr3 X m n)) -> forall m : mytype X, <math>P m \square$

Exercise: 1 star, optional (foo) Find an inductive definition that gives rise to the following induction principle: foo_ind: forall (X Y: Type) (P: foo X Y -> Prop), (forall x: X, P (bar X Y x)) -> (forall y: Y, P (baz X Y y)) -> (forall f1: nat -> foo X Y, (forall n: nat, P (f1 n)) -> P (quux X Y f1)) -> forall f2: foo X Y, P f2 \square

Exercise: 1 star, optional (foo') Consider the following inductive definition:

```
Inductive foo' (X:Type): Type := |C1: list X \rightarrow foo' X \rightarrow foo' X | C2: foo' X.
```

7.5.2 Induction Hypotheses

Where does the phrase "induction hypothesis" fit into this story?

The induction principle for numbers for all P : nat -> Prop, P 0 -> (for all n : nat, P n -> P (S n)) -> for all n : nat, P n is a generic statement that holds for all propositions <math>P (strictly speaking, for all families of propositions P indexed by a number n). Each time we use this principle, we are choosing P to be a particular expression of type $nat \rightarrow Prop$.

We can make the proof more explicit by giving this expression a name. For example, instead of stating the theorem $mult_0_r$ as " $\forall n, n \times 0 = 0$," we can write it as " $\forall n, P_m0r$ n", where P_m0r is defined as...

```
Definition P_m0r (n:nat): Prop := n \times 0 = 0.
... or equivalently...
```

```
Definition P_-m0r': nat \rightarrow Prop := fun \ n \Rightarrow n \times 0 = 0.

Now when we do the proof it is easier to see where P_-m0r appears. Theorem mult_0 r'': \forall n:nat, P_-m0r \ n.

Proof.

apply nat\_ind.

Case \ "n = O". reflexivity.

Case \ "n = S \ n'".

unfold P_-m0r. simpl. intros n' IHn'.

apply IHn'. Qed.
```

This extra naming step isn't something that we'll do in normal proofs, but it is useful to do it explicitly for an example or two, because it allows us to see exactly what the induction hypothesis is. If we prove $\forall n, P_-m\theta r$ n by induction on n (using either induction or apply nat_ind), we see that the first subgoal requires us to prove $P_-m\theta r$ 0 ("P holds for zero"), while the second subgoal requires us to prove $\forall n', P_-m\theta r$ $n' \rightarrow P_-m\theta r$ n' (S n') (that is "P holds of S n' if it holds of n''' or, more elegantly, "P is preserved by S"). The induction hypothesis is the premise of this latter implication – the assumption that P holds of n', which we are allowed to use in proving that P holds for S n'.

7.6 Optional Material

This section offers some additional details on how induction works in Coq and the process of building proof trees. It can safely be skimmed on a first reading. (We recommend skimming rather than skipping over it outright: it answers some questions that occur to many Coq users at some point, so it is useful to have a rough idea of what's here.)

7.6.1 Induction Principles in Prop

Earlier, we looked in detail at the induction principles that Coq generates for inductively defined sets. The induction principles for inductively defined propositions like gorgeous are a tiny bit more complicated. As with all induction principles, we want to use the induction principle on gorgeous to prove things by inductively considering the possible shapes that something in gorgeous can have – either it is evidence that 0 is gorgeous, or it is evidence that, for some n, 3+n is gorgeous, or it is evidence that, for some n, 5+n is gorgeous and it includes evidence that n itself is. Intuitively speaking, however, what we want to prove are not statements about evidence but statements about numbers. So we want an induction principle that lets us prove properties of numbers by induction on evidence.

For example, from what we've said so far, you might expect the inductive definition of gorgeous... Inductive gorgeous: nat -> Prop := g_0 : gorgeous $0 \mid g_plus : for all n, gorgeous <math>1 \mid g_plus : for all n, gorgeous n -> gorgeous <math>1 \mid g_plus : for all n, gorgeous n -> gorgeous <math>1 \mid g_plus : for all n, gorgeous n -> gorgeous <math>1 \mid g_plus : for all n, gorgeous n -> gorgeous <math>1 \mid g_plus : for all n, gorgeous n -> gorgeous <math>1 \mid g_plus : for all n, gorgeous :$

an induction principle that looks like this... gorgeous_ind_max : forall P : (forall n : nat, gorgeous n -> Prop), P O g_0 -> (forall (m : nat) (e : gorgeous m), P m e -> P (3+m) (g_plus3 m e) -> (forall (m : nat) (e : gorgeous m), P m e -> P (5+m) (g_plus5 m e) -> forall (n : nat) (e : gorgeous n), P n e ... because:

- Since gorgeous is indexed by a number n (every gorgeous object e is a piece of evidence that some particular number n is gorgeous), the proposition P is parameterized by both n and e that is, the induction principle can be used to prove assertions involving both a gorgeous number and the evidence that it is gorgeous.
- Since there are three ways of giving evidence of gorgeousness (*gorgeous* has three constructors), applying the induction principle generates three subgoals:
 - We must prove that P holds for O and $b_-\theta$.
 - We must prove that, whenever n is a gorgeous number and e is an evidence of its gorgeousness, if P holds of n and e, then it also holds of 3+m and g_plus3 n e.
 - We must prove that, whenever n is a gorgeous number and e is an evidence of its gorgeousness, if P holds of n and e, then it also holds of 5+m and $g_plus_n or e$.
- If these subgoals can be proved, then the induction principle tells us that P is true for all gorgeous numbers n and evidence e of their gorgeousness.

Check gorgeous_ind.

In particular, Coq has dropped the evidence term e as a parameter of the the proposition P, and consequently has rewritten the assumption $\forall (n : nat) (e: gorgeous n)$, ... to be $\forall (n : nat)$, $gorgeous n \rightarrow ...$; i.e., we no longer require explicit evidence of the provability of gorgeous n.

In English, gorgeous_ind says:

- Suppose, P is a property of natural numbers (that is, P n is a Prop for every n). To show that P n holds whenever n is gorgeous, it suffices to show:
 - -P holds for 0,
 - for any n, if n is gorgeous and P holds for n, then P holds for 3+n,

- for any n, if n is gorgeous and P holds for n, then P holds for 5+n.

We can apply *gorgeous_ind* directly instead of using induction.

```
Theorem gorgeous_beautiful': \forall n, gorgeous n \rightarrow beautiful n.
Proof.
    intros.
    apply gorgeous_ind.
    Case "g_0".
          apply b_0.
    Case "g_plus3".
          intros.
          apply b_sum. apply b_3.
          apply H1.
    Case "g_plus5".
          intros.
          apply b_sum. apply b_5.
          apply H1.
    apply H.
Qed.
Module P.
Exercise: 3 stars, optional (p_provability) Consider the following inductively defined
proposition:
Inductive \mathbf{p}: (\mathbf{tree} \ \mathbf{nat}) \rightarrow \mathbf{nat} \rightarrow \mathsf{Prop} :=
    \mid c1 : \forall n, p (leaf \_ n) 1
    \mid c2 : \forall t1 t2 n1 n2,
                 \mathbf{p} \ t1 \ n1 \rightarrow \mathbf{p} \ t2 \ n2 \rightarrow \mathbf{p} \ (\mathsf{node} \ \_ \ t1 \ t2) \ (n1 + n2)
```

Describe, in English, the conditions under which the proposition $p \ t \ n$ is provable.

End P.

7.6.2 More on the induction Tactic

 $\mid c3 : \forall t \ n, \ \mathbf{p} \ t \ n \rightarrow \mathbf{p} \ t \ (S \ n).$

The induction tactic actually does even more low-level bookkeeping for us than we discussed above.

Recall the informal statement of the induction principle for natural numbers:

- If P n is some proposition involving a natural number n, and we want to show that P holds for all numbers n, we can reason like this:
 - show that P O holds

```
- show that, if P n' holds, then so does P (S n')
```

So, when we begin a proof with intros n and then induction n, we are first telling Coq to consider a particular n (by introducing it into the context) and then telling it to prove something about all numbers (by using induction).

What Coq actually does in this situation, internally, is to "re-generalize" the variable we perform induction on. For example, in the proof above that *plus* is associative...

```
Theorem plus_assoc' : \forall n \ m \ p : nat,
  n + (m + p) = (n + m) + p.
Proof.
  intros n m p.
  induction n as [\mid n'].
  Case "n = O". reflexivity.
  Case "n = S n".
    simpl. rewrite \rightarrow IHn'. reflexivity. Qed.
   It also works to apply induction to a variable that is quantified in the goal.
Theorem plus_comm': \forall n m : nat,
  n + m = m + n.
Proof.
  induction n as [\mid n'].
  Case "n = O". intros m. rewrite \rightarrow plus_0_r. reflexivity.
  Case "n = S n'". intros m. simpl. rewrite \rightarrow IHn'.
    rewrite \leftarrow plus_n\_Sm. reflexivity. Qed.
```

Note that induction n leaves m still bound in the goal – i.e., what we are proving inductively is a statement beginning with $\forall m$.

If we do induction on a variable that is quantified in the goal *after* some other quantifiers, the induction tactic will automatically introduce the variables bound by these quantifiers into the context.

```
Theorem plus_comm": \forall \ n \ m: \mathbf{nat}, n+m=m+n.

Proof.

induction m as [\mid m'].

Case \ "m=O". \ simpl. \ rewrite \rightarrow plus_O\_r. \ reflexivity.

Case \ "m=S \ m'". \ simpl. \ rewrite \leftarrow IHm'.

rewrite \leftarrow plus\_n\_Sm. \ reflexivity. \ Qed.
```

Exercise: 1 star, optional (plus_explicit_prop) Rewrite both $plus_assoc'$ and $plus_comm'$ and their proofs in the same style as $mult_a - 0 - r''$ above – that is, for each theorem, give an explicit Definition of the proposition being proved by induction, and state the theorem and proof in terms of this defined proposition.

⁻ conclude that P n holds for all n.

One more quick digression, for adventurous souls: if we can define parameterized propositions using Definition, then can we also define them using Fixpoint? Of course we can! However, this kind of "recursive parameterization" doesn't correspond to anything very familiar from everyday mathematics. The following exercise gives a slightly contrived example.

Exercise: 4 stars, optional (true_upto_n_true_everywhere) Define a recursive function $true_upto_n_true_everywhere$ that makes $true_upto_n_example$ work.

7.6.3 Building Proof Objects Incrementally

As you probably noticed while solving the exercises earlier in the chapter, constructing proof objects is more involved than constructing the corresponding tactic proofs. Fortunately, there is a bit of syntactic sugar that we've already introduced to help in the construction: the *admit* term, which we've sometimes used to force Coq into accepting incomplete exercise. As an example, let's walk through the process of constructing a proof object demonstrating the beauty of 16.

```
Definition b_16_atmpt_1 : beautiful 16 := admit.
```

Maybe we can use b_sum to construct a term of type beautiful 16? Recall that b_sum is of type

```
for
all n m : nat, beautiful n -> beautiful m -> beautiful (n + m)
```

If we can demonstrate the beauty of 5 and 11, we should be done.

```
Definition b_16_atmpt_2: beautiful 16 := b_sum 5 11 admit admit.
```

In the attempt above, we've omitted the proofs of the propositions that 5 and 11 are beautiful. But the first of these is already axiomatized in b_-5 :

```
Definition b_16_atmpt_3: beautiful 16 := b_sum 5 11 b_5 admit.
```

What remains is to show that 11 is beautiful. We repeat the procedure:

```
Definition b_16_atmpt_4 : beautiful 16 :=
   b_sum 5 11 b_5 (b_sum 5 6 admit admit).

Definition b_16_atmpt_5 : beautiful 16 :=
   b_sum 5 11 b_5 (b_sum 5 6 b_5 admit).

Definition b_16_atmpt_6 : beautiful 16 :=
   b_sum 5 11 b_5 (b_sum 5 6 b_5 (b_sum 3 3 admit admit)).

And finally, we can complete the proof object:

Definition b_16 : beautiful 16 :=
   b_sum 5 11 b_5 (b_sum 5 6 b_5 (b_sum 3 3 b_3 b_3)).
```

To recap, we've been guided by an informal proof that we have in our minds, and we check the high level details before completing the intricacies of the proof. The *admit* term allows us to do this.

7.7 Additional Exercises

Exercise: 4 stars, recommended (palindromes) A palindrome is a sequence that reads the same backwards as forwards.

• Define an inductive proposition *pal* on *list X* that captures what it means to be a palindrome. (Hint: You'll need three cases. Your definition should be based on the structure of the list; just having a single constructor

c: for all $l, l = rev l \rightarrow pal l may seem obvious, but will not work very well.)$

- Prove that forall l, pal (l ++ rev l).
- Prove that for all l, pal $l \rightarrow l = rev l$.

Exercise: 5 stars, optional (palindrome_converse) Using your definition of pal from the previous exercise, prove that for all l, l = rev l -> pal l.

Exercise: 4 stars (subsequence) A list is a *subsequence* of another list if all of the elements in the first list occur in the same order in the second list, possibly with some extra elements in between. For example, 1,2,3 is a subsequence of each of the lists 1,2,3 1,1,1,2,2,3 1,2,7,3 5,6,1,9,9,2,7,3,8 but it is *not* a subsequence of any of the lists 1,2 1,3 5,6,2,1,7,3,8

- Define an inductive proposition *subseq* on *list nat* that captures what it means to be a subsequence. (Hint: You'll need three cases.)
- Prove that subsequence is reflexive, that is, any list is a subsequence of itself.
- Prove that for any lists l1, l2, and l3, if l1 is a subsequence of l2, then l1 is also a subsequence of l2 ++ l3.
- (Optional, harder) Prove that subsequence is transitive that is, if l1 is a subsequence of l2 and l2 is a subsequence of l3, then l1 is a subsequence of l3. Hint: choose your induction carefully!

Exercise: 2 stars, optional (foo_ind_principle) Suppose we make the following inductive definition: Inductive foo (X : Set) (Y : Set) : Set := foo1 : X -> foo X Y foo2 : Y -> foo X Y foo3 : foo X Y -> foo X Y. Fill in the blanks to complete the induction principle that will be generated by Coq. foo_ind : forall (X Y : Set) (P : foo X Y -> Prop), (forall x : X,) -> (forall y : Y,)	
->	
Exercise: 2 stars, optional (bar_ind_principle) Consider the following induction principle: bar_ind: forall P: bar -> Prop, (forall n: nat, P (bar1 n)) -> (forall b: bar, P b -> P (bar2 b)) -> (forall (b: bool) (b0: bar), P b0 -> P (bar3 b b0)) -> forall b: bar, P b Write out the corresponding inductive set definition. Inductive bar: Set := bar1: bar2:	
bar3 :	
Exercise: 2 stars, optional (no_longer_than_ind) Given the following inductively defined proposition: Inductive no_longer_than $(X : Set) : (list X) -> nat -> Prop := nlt_nil : forall n, no_longer_than X \square n nlt_cons : forall x l n, no_longer_than X l n -> no_longer_than X (x::l) (S n) nlt_succ : forall l n, no_longer_than X l n -> no_longer_than X l (S n). write the induction principle generated by Coq. no_longer_than_ind : forall (X : Set) (P : list X -> nat -> Prop), (forall n : nat,) -> (forall (x : X) (l : list X) (n : nat), no_longer_than (x : X) (n : nat)$	
Exercise: 2 stars, optional (R_provability) Suppose we give Coq the following definition: Inductive R: nat -> list nat -> Prop := $ c1 + c1 + c2 + c3 + c3$	

 $(n::l) \mid c3:$ for all n l, R (S n) l -> R n l. Which of the following propositions are provable?

- R 2 [1,0]
- R 1 [1,2,1,0]
- R 6 [3,2,1,0]

Chapter 8

Library Logic

8.1 Logic: Logic in Coq

Require Export "Prop".

Coq's built-in logic is extremely small: only Inductive definitions, universal quantification (\forall) , and implication (\rightarrow) are primitive, while all the other familiar logical connectives – conjunction, disjunction, negation, existential quantification, even equality – can be defined using just these.

8.2 Quantification and Implication

In fact, \rightarrow and \forall are the *same* primitive! Coq's \rightarrow notation is actually just a shorthand for \forall . The \forall notation is more general, because it allows us to *name* the hypothesis.

For example, consider this proposition:

```
Definition funny_prop1 := \forall n, \forall (E : \mathbf{beautiful} \ n), \mathbf{beautiful} \ (n+3).
```

If we had a proof term inhabiting this proposition, it would be a function with two arguments: a number n and some evidence that n is beautiful. But the name E for this evidence is not used in the rest of the statement of $funny_prop1$, so it's a bit silly to bother making up a name. We could write it like this instead, using the dummy identifier $_$ in place of a real name:

```
Definition funny_prop1' := \forall n, \forall (\_: beautiful \ n), beautiful (n+3). Or, equivalently, we can write it in more familiar notation: Definition funny_prop1'' := \forall n, beautiful \ n \rightarrow beautiful \ (n+3). This illustrates that "P \rightarrow Q" is just syntactic sugar for "\forall (\_:P), \ Q".
```

8.3 Conjunction

The logical conjunction of propositions P and Q can be represented using an Inductive definition with one constructor.

```
Inductive and (P \ Q : Prop) : Prop := conj : P \rightarrow Q \rightarrow (and P \ Q).
```

Note that, like the definition of ev in the previous chapter, this definition is parameterized; however, in this case, the parameters are themselves propositions, rather than numbers.

The intuition behind this definition is simple: to construct evidence for and P Q, we must provide evidence for P and evidence for Q. More precisely:

- $conj \ p \ q$ can be taken as evidence for $and \ P \ Q$ if p is evidence for P and q is evidence for Q; and
- this is the *only* way to give evidence for and P Q that is, if someone gives us evidence for and P Q, we know it must have the form conj p q, where p is evidence for P and q is evidence for Q.

Since we'll be using conjunction a lot, let's introduce a more familiar-looking infix notation for it.

```
Notation "P /\ Q" := (and P Q) : type\_scope.
```

(The *type_scope* annotation tells Coq that this notation will be appearing in propositions, not values.)

Consider the "type" of the constructor *conj*:

Check conj.

Notice that it takes 4 inputs – namely the propositions P and Q and evidence for P and Q – and returns as output the evidence of $P \wedge Q$.

Besides the elegance of building everything up from a tiny foundation, what's nice about defining conjunction this way is that we can prove statements involving conjunction using the tactics that we already know. For example, if the goal statement is a conjuction, we can prove it by applying the single constructor *conj*, which (as can be seen from the type of *conj*) solves the current goal and leaves the two parts of the conjunction as subgoals to be proved separately.

```
Theorem and_example:
   (beautiful 0) ∧ (beautiful 3).

Proof.
   apply conj.
   apply b_0.
   apply b_3. Qed.

Let's take a look at the proof object for the above theorem.
```

Print and_example.

Note that the proof is of the form conj (beautiful 0) (beautiful 3) (...pf of beautiful 3...) (...pf of beautiful 3...) as you'd expect, given the type of *conj*.

Just for convenience, we can use the tactic split as a shorthand for apply conj.

```
Theorem and_example':  \begin{array}{l} (\textbf{ev}\ 0)\ \land\ (\textbf{ev}\ 4). \\ \\ \textbf{Proof.} \\ \textbf{split.} \\ \textbf{\it Case}\ "left".\ apply\ ev\_0. \\ \textbf{\it Case}\ "right".\ apply\ ev\_SS.\ apply\ ev\_SS.\ apply\ ev\_0.\ \ \ \ \ \ \end{array}
```

Conversely, the inversion tactic can be used to take a conjunction hypothesis in the context, calculate what evidence must have been used to build it, and add variables representing this evidence to the proof context.

```
Theorem proj1: \forall P \ Q : Prop,
  P \wedge Q \rightarrow P.
Proof.
  intros P Q H.
  inversion H as [HP \ HQ].
  apply HP. Qed.
Exercise: 1 star, optional (proj2) Theorem proj2 : \forall P Q : Prop.
  P \wedge Q \rightarrow Q.
Proof.
    Admitted.
   Theorem and_commut : \forall P \ Q : Prop,
  P \wedge Q \rightarrow Q \wedge P.
Proof.
  intros P \ Q \ H.
  inversion H as [HP \ HQ].
  split.
   apply HQ.
   apply HP. Qed.
```

Once again, we have commented out the Case tactics to make the proof object for this theorem easy to understand. Examining it shows that all that is really happening is taking apart a record containing evidence for P and Q and rebuilding it in the opposite order:

Print and_commut.

Exercise: 2 stars (and_assoc) In the following proof, notice how the *nested pattern* in the inversion breaks the hypothesis $H: P \wedge (Q \wedge R)$ down into HP: P, HQ: Q, and HR: R. Finish the proof from there:

```
Theorem and assoc : \forall P \ Q \ R : Prop, P \land (Q \land R) \rightarrow (P \land Q) \land R.

Proof.

intros P \ Q \ R \ H.

inversion H as [HP \ [HQ \ HR]].

Admitted.
```

Exercise: 2 stars, recommended (even__ev) Now we can prove the other direction of the equivalence of even and ev, which we left hanging in chapter Prop. Notice that the left-hand conjunct here is the statement we are actually interested in; the right-hand conjunct is needed in order to make the induction hypothesis strong enough that we can carry out the reasoning in the inductive step. (To see why this is needed, try proving the left conjunct by itself and observe where things get stuck.)

```
Theorem even__ev : \forall n : \operatorname{nat},   (even n \to \operatorname{ev} n) \wedge (even (S n) \to \operatorname{ev} (S n)). Proof.

Admitted.
```

Exercise: 2 stars, optional (conj_fact) Construct a proof object demonstrating the following proposition.

```
Definition conj_fact : \forall \ P \ Q \ R, \ P \land Q \to Q \land R \to P \land R := admit. \Box
```

8.3.1 Iff

The familiar logical "if and only if" is just the conjunction of two implications.

```
\begin{array}{l} \text{Definition iff } (P\ Q: \operatorname{Prop}) := (P \to Q) \ \land \ (Q \to P). \\ \text{Notation "P <-> Q"} := (\text{iff } P\ Q) \\ \qquad \qquad \qquad (\text{at level } 95, \, \text{no associativity}) : \ type\_scope. \\ \text{Theorem iff\_implies : } \forall \ P\ Q : \operatorname{Prop}, \\ (P \leftrightarrow Q) \to P \to Q. \\ \text{Proof.} \\ \text{intros } P\ Q\ H. \\ \text{inversion } H \text{ as } [HAB\ HBA]. \text{ apply } HAB. \, \mathrm{Qed.} \\ \text{Theorem iff\_sym : } \forall \ P\ Q : \operatorname{Prop}, \\ (P \leftrightarrow Q) \to (Q \leftrightarrow P). \\ \text{Proof.} \\ \text{intros } P\ Q\ H. \\ \end{array}
```

```
inversion H as [HAB\ HBA]. split. 
 Case "->". apply HBA. Case "<-". apply HAB. Qed.
```

Exercise: 1 star, optional (iff_properties) Using the above proof that \leftrightarrow is symmetric (iff_sym) as a guide, prove that it is also reflexive and transitive.

```
Theorem iff_refl : \forall P : Prop, P \leftrightarrow P.

Proof. Admitted.

Theorem iff_trans : \forall P \ Q \ R : Prop, (P \leftrightarrow Q) \rightarrow (Q \leftrightarrow R) \rightarrow (P \leftrightarrow R).

Proof. Admitted.
```

Hint: If you have an iff hypothesis in the context, you can use inversion to break it into two separate implications. (Think about why this works.) \square

Exercise: 2 stars, optional (beautiful_iff_gorgeous) We have seen that the families of propositions beautiful and gorgeous actually characterize the same set of numbers. Prove that beautiful $n \leftrightarrow gorgeous$ n for all n. Just for fun, write your proof as an explicit proof object, rather than using tactics. (Hint: if you make use of previously defined theorems, you should only need a single line!)

```
Definition beautiful_iff_gorgeous : \forall n, beautiful n \leftrightarrow \text{gorgeous } n := admit.
```

Some of Coq's tactics treat *iff* statements specially, thus avoiding the need for some low-level manipulation when reasoning with them. In particular, **rewrite** can be used with *iff* statements, not just equalities.

8.4 Disjunction

Disjunction ("logical or") can also be defined as an inductive proposition.

```
Inductive or (P \ Q : \operatorname{Prop}) : \operatorname{Prop} := | \operatorname{or\_introl} : P \to \operatorname{or} P \ Q | \operatorname{or\_intror} : Q \to \operatorname{or} P \ Q.
Notation "P \/ Q" := (or P \ Q) : type\_scope.

Consider the "type" of the constructor or\_introl:
```

Check or_introl.

It takes 3 inputs, namely the propositions P, Q and evidence of P, and returns, as output, the evidence of $P \vee Q$. Next, look at the type of or_intror :

Check or_intror.

It is like or_introl but it requires evidence of Q instead of evidence of P. Intuitively, there are two ways of giving evidence for $P \vee Q$:

- give evidence for P (and say that it is P you are giving evidence for this is the function of the or_introl constructor), or
- give evidence for Q, tagged with the $or_{-}intror$ constructor.

Since $P \vee Q$ has two constructors, doing inversion on a hypothesis of type $P \vee Q$ yields two subgoals.

```
Theorem or_commut : \forall \ P \ Q : Prop, P \lor Q \to Q \lor P.

Proof.

intros P \ Q \ H.

inversion H as [HP \mid HQ].

Case "left". apply or_intror. apply HP.

Case "right". apply or_introl. apply HQ. Qed.
```

From here on, we'll use the shorthand tactics left and right in place of apply or_introl and apply or_intror .

```
Theorem or_commut': \forall \ P \ Q: Prop, P \lor Q \to Q \lor P.

Proof.
intros P \ Q \ H.
inversion H as [HP \mid HQ].
Case "left". right. apply HP.
Case "right". left. apply HQ. Qed.
```

Exercise: 2 stars, optional (or_commut") Try to write down an explicit proof object for *or_commut* (without using Print to peek at the ones we already defined!).

```
Theorem or_distributes_over_and_1 : \forall \ P \ Q \ R : Prop, P \lor (Q \land R) \to (P \lor Q) \land (P \lor R).

Proof.
intros P \ Q \ R. intros H. inversion H as [HP \mid [HQ \ HR]].
Case \text{ "left". split.}
SCase \text{ "left". left. apply } HP.
SCase \text{ "right". left. apply } HP.
```

```
Case "right". split. SCase "left". right. apply HQ. SCase "right". right. apply HR. Qed.

Exercise: 2 stars, recommended (or_distributes_over_and_2) Theorem or_distributes_over_and_2: \forall P \mid Q \mid R: Prop, (P \lor Q) \land (P \lor R) \rightarrow P \lor (Q \land R). Proof. Admitted.

Exercise: 1 star, optional (or_distributes_over_and) Theorem or_distributes_over_and: \forall P \mid Q \mid R: Prop, P \lor (Q \land R) \leftrightarrow (P \lor Q) \land (P \lor R). Proof. Admitted.
```

8.4.1 Relating \wedge and \vee with and b and b

We've already seen several places where analogous structures can be found in Coq's computational (Type) and logical (Prop) worlds. Here is one more: the boolean operators andb and orb are clearly analogs of the logical connectives \land and \lor . This analogy can be made more precise by the following theorems, which show how to translate knowledge about andb and orb's behaviors on certain inputs into propositional facts about those inputs.

```
Theorem andb_true__and : \forall b \ c, andb b \ c = true \rightarrow b = true \land c = true. Proof. intros b \ c \ H. destruct b.  
Case \ "b = true". \ destruct \ c. SCase \ "c = true". \ apply \ conj. \ reflexivity. \ reflexivity. \ SCase \ "c = false". \ inversion \ H. \ Case \ "b = false". \ inversion \ H. \ Qed.
Theorem and __andb_true : \forall b \ c, b = true \land c = true \rightarrow andb \ b \ c = true. Proof. intros b \ c \ H. inversion H. rewrite H0. rewrite H1. reflexivity. Qed.
```

```
Exercise: 2 stars (bool_prop) Theorem andb_false : \forall \ b \ c, andb b \ c = false \rightarrow b = false \lor c = false.

Proof.

Admitted.

Theorem orb_true : \forall \ b \ c, orb b \ c = true \rightarrow b = true \lor c = true.

Proof.

Admitted.

Theorem orb_false : \forall \ b \ c, orb b \ c = false \rightarrow b = false \land c = false.

Proof.

Admitted.

\Box
```

8.5 Falsehood

Logical falsehood can be represented in Coq as an inductively defined proposition with no constructors.

Inductive False : Prop := .

Intuition: False is a proposition for which there is no way to give evidence.

Exercise: 1 star (False_ind_principle) Can you predict the induction principle for falsehood?

Since False has no constructors, inverting an assumption of type False always yields zero subgoals, allowing us to immediately prove any goal.

Theorem False_implies_nonsense:

```
False \rightarrow 2 + 2 = 5.
```

Proof.

intros contra.

inversion contra. Qed.

How does this work? The inversion tactic breaks *contra* into each of its possible cases, and yields a subgoal for each case. As *contra* is evidence for *False*, it has *no* possible cases, hence, there are no possible subgoals and the proof is done.

Conversely, the only way to prove *False* is if there is already something nonsensical or contradictory in the context:

```
Theorem nonsense_implies_False:
```

```
2 + 2 = 5 \rightarrow \mathsf{False}.
```

Proof.

```
intros contra. inversion contra. Qed.
```

Actually, since the proof of $False_implies_nonsense$ doesn't actually have anything to do with the specific nonsensical thing being proved; it can easily be generalized to work for an arbitrary P:

```
Theorem ex_falso_quodlibet : \forall (P:Prop), False \rightarrow P.

Proof. intros P contra. inversion contra. Qed.
```

The Latin *ex falso quodlibet* means, literally, "from falsehood follows whatever you please." This theorem is also known as the *principle of explosion*.

8.5.1 Truth

Since we have defined falsehood in Coq, one might wonder whether it is possible to define truth in the same way. We can.

Exercise: 2 stars, optional (True_induction) Define *True* as another inductively defined proposition. What induction principle will Coq generate for your definition? (The intution is that *True* should be a proposition for which it is trivial to give evidence. Alternatively, you may find it easiest to start with the induction principle and work backwards to the inductive definition.)

However, unlike *False*, which we'll use extensively, *True* is just a theoretical curiosity: it is trivial (and therefore uninteresting) to prove as a goal, and it carries no useful information as a hypothesis.

8.6 Negation

The logical complement of a proposition P is written not P or, for shorthand, $\neg P$:

```
{\tt Definition\ not\ }(P{:}{\tt Prop}):=P\to {\sf False}.
```

The intuition is that, if P is not true, then anything at all (even False) follows from assuming P.

```
Notation "\tilde{} x" := (not x) : type\_scope. Check not.
```

It takes a little practice to get used to working with negation in Coq. Even though you can see perfectly well why something is true, it can be a little hard at first to get things into

the right configuration so that Coq can see it! Here are proofs of a few familiar facts about negation to get you warmed up.

```
Theorem not_False:
  ¬ False.
Proof.
  unfold not. intros H. inversion H. Qed.
Theorem contradiction_implies_anything : \forall P \ Q : Prop,
  (P \land \neg P) \rightarrow Q.
Proof.
  intros P \ Q \ H. inversion H as [HP \ HNA]. unfold not in HNA.
  apply HNA in HP. inversion HP. Qed.
Theorem double_neg : \forall P : Prop,
  P \rightarrow \tilde{P}.
Proof.
  intros P H. unfold not. intros G. apply G. apply H. Qed.
Exercise: 2 stars, recommended (double_neg_inf) Write an informal proof of dou-
ble\_neg:
   Theorem: P implies \tilde{P}, for any proposition P.
   Proof: \square
Exercise: 2 stars, recommended (contrapositive) Theorem contrapositive: \forall P Q:
  (P \to Q) \to (\neg Q \to \neg P).
Proof.
   Admitted.
Exercise: 1 star (not_both_true_and_false) Theorem not_both_true_and_false : \forall P
: Prop,
  \neg (P \land \neg P).
Proof.
   Admitted.
   Exercise: 1 star (informal_not_PNP) Write an informal proof (in English) of the
proposition \forall P : \text{Prop}, \ \tilde{\ } (P \land \neg P).
Theorem five_not_even :
  \neg ev 5.
```

Proof.

```
unfold not. intros Hev5. inversion Hev5 as [|n| Hev3| Heqn]. inversion Hev3 as [|n'| Hev1| Heqn']. inversion Hev1. Qed.
```

Exercise: 1 star (ev_not_ev_S) Theorem five_not_even confirms the unsurprising fact that five is not an even number. Prove this more interesting fact:

```
Theorem ev_not_ev_S : \forall n, ev n \to \neg ev (S \ n). Proof. unfold not. intros n H. induction H. Admitted. \Box
```

Note that some theorems that are true in classical logic are *not* provable in Coq's (constructive) logic. E.g., let's look at how this proof gets stuck...

Exercise: 5 stars, optional (classical_axioms) For those who like a challenge, here is an exercise taken from the Coq'Art book (p. 123). The following five statements are often considered as characterizations of classical logic (as opposed to constructive logic, which is what is "built in" to Coq). We can't prove them in Coq, but we can consistently add any one of them as an unproven axiom if we wish to work in classical logic. Prove that these five propositions are equivalent.

8.6.1 Inequality

```
Saying x \neq y is just the same as saying (x = y).
Notation "x <> y" := (\neg (x = y)) : type\_scope.
```

Since inequality involves a negation, it again requires a little practice to be able to work with it fluently. Here is one very useful trick. If you are trying to prove a goal that is nonsensical (e.g., the goal state is false = true), apply the lemma $ex_falso_quodlibet$ to change the goal to False. This makes it easier to use assumptions of the form $\neg P$ that are available in the context – in particular, assumptions of the form $x \neq y$.

```
Theorem not_false_then_true : \forall b : \mathbf{bool},
  b \neq \mathsf{false} \rightarrow b = \mathsf{true}.
Proof.
  intros b H. destruct b.
  Case "b = true". reflexivity.
  Case "b = false".
     unfold not in H.
     apply ex_falso_quodlibet.
     apply H. reflexivity. Qed.
Exercise: 2 stars, recommended (not_eq_beq_false) Theorem not_eq_beq_false: \forall
n n' : \mathbf{nat},
      n \neq n' \rightarrow
      beq_nat n = \text{false}.
Proof.
    Admitted.
   Exercise: 2 stars, optional (beq_false_not_eq) Theorem beq_false_not_eq: \forall n m,
  false = beq_nat n m \rightarrow n \neq m.
Proof.
    Admitted.
```

8.7 Existential Quantification

Another critical logical connective is *existential quantification*. We can capture what this means with the following definition:

```
Inductive ex (X:Type) (P: X \rightarrow Prop) : Prop := ex_intro : <math>\forall (witness:X), P \ witness \rightarrow ex \ X \ P.
```

That is, ex is a family of propositions indexed by a type X and a property P over X. In order to give evidence for the assertion "there exists an x for which the property P holds" we must actually name a witness – a specific value x – and then give evidence for P x, i.e., evidence that x has the property P.

For example, consider this existentially quantified proposition:

```
Definition some_nat_is_even : Prop :=
```

ex nat ev.

To prove this proposition, we need to choose a particular number as witness - say, 4 - and give some evidence that that number is even.

```
Definition snie : some_nat_is_even :=
  ex_intro _ ev 4 (ev_SS 2 (ev_SS 0 ev_0)).
```

Coq's notation definition facility can be used to introduce more familiar notation for writing existentially quantified propositions, exactly parallel to the built-in syntax for universally quantified propositions. Instead of writing ex nat ev to express the proposition that there exists some number that is even, for example, we can write $\exists x:nat, ev x$. (It is not necessary to understand exactly how the Notation definition works.)

```
Notation "'exists' x , p" := (ex _ (fun x \Rightarrow p)) (at level 200, x ident, right associativity) : type\_scope. Notation "'exists' x : X , p" := (ex _ (fun x:X \Rightarrow p)) (at level 200, x ident, right associativity) : type\_scope.
```

We can use the same set of tactics as always for manipulating existentials. For example, if to prove an existential, we apply the constructor ex_intro . Since the premise of ex_intro involves a variable (witness) that does not appear in its conclusion, we need to explicitly give its value when we use apply.

```
Example exists_example_1 : \exists n, n + (n × n) = 6. 
Proof. 
apply ex_intro with (witness:=2). 
reflexivity. Qed.
```

Note, again, that we have to explicitly give the witness.

Or, instead of writing apply ex_intro with (witness := e) all the time, we can use the convenient shorthand $\exists e$, which means the same thing.

```
Example exists_example_1': \exists n, n + (n \times n) = 6.

Proof. \exists 2. reflexivity. Qed.
```

Conversely, if we have an existential hypothesis in the context, we can eliminate it with inversion. Note the use of the as... pattern to name the variable that Coq introduces to name the witness value and get evidence that the hypothesis holds for the witness. (If we don't explicitly choose one, Coq will just call it witness, which makes proofs confusing.)

```
Theorem exists_example_2 : \forall n, (\exists m, n = 4 + m) \rightarrow (\exists o, n = 2 + o).

Proof.

intros n H.

inversion H as [m \ Hm].
```

```
\exists (2+m). apply Hm. Qed.
```

Exercise: 1 star, optional (english_exists) In English, what does the proposition ex nat (fun n = beautiful (S n)) || mean?

Complete the definition of the following proof object:

```
Definition p : ex nat (fun n \Rightarrow beautiful (S n)) := admit.
```

Exercise: 1 star (dist_not_exists) Prove that "P holds for all x" and "there is no x for which P does not hold" are equivalent assertions.

```
Theorem dist_not_exists : \forall (X:Type) (P: X \to \text{Prop}), (\forall x, P x) \to \neg (\exists x, \neg P x).

Proof.

Admitted.
```

Exercise: 3 stars, optional (not_exists_dist) The other direction requires the classical "law of the excluded middle":

```
Theorem not_exists_dist:
\begin{array}{l} \text{excluded\_middle} \rightarrow \\ \forall \ (X\text{:Type}) \ (P:X \rightarrow \text{Prop}), \\ \neg \ (\exists \ x \text{, } \neg \ P \ x) \rightarrow (\forall \ x, \ P \ x). \\ \\ \text{Proof.} \\ Admitted. \\ \square \end{array}
```

Exercise: 2 stars (dist_exists_or) Prove that existential quantification distributes over disjunction.

```
Theorem dist_exists_or : \forall (X:Type) (P Q : X \to Prop), (\exists x, P x \lor Q x) \leftrightarrow (\exists x, P x) \lor (\exists x, Q x). Proof.

Admitted.
```

8.8 Equality

Even Coq's equality relation is not built in. It has roughly the following inductive definition. (We enclose the definition in a module to avoid confusion with the standard library equality,

which we have used extensively already.)

Module MYEQUALITY.

```
Inductive eq (X:Type): X \to X \to Prop := refl_equal: \forall x, eq X x x.
```

Standard infix notation (using Coq's type argument synthesis):

```
Notation "x = y" := (eq _ x y)
(at level 70, no associativity) : type\_scope.
```

This is a bit subtle. The way to think about it is that, given a set X, it defines a family of propositions "x is equal to y," indexed by pairs of values (x and y) from X. There is just one way of constructing evidence for members of this family: applying the constructor $refl_equal$ to a type X and a value x:X yields evidence that x is equal to x.

Here is a slightly different definition – the one that actually appears in the Coq standard library.

```
Inductive eq' (X:Type) (x:X): X \to Prop := refl_equal': eq' <math>X x x.

Notation "x = y' := (eq' _x y) (at level 70, no associativity): type\_scope.
```

Exercise: 3 stars, optional (two_defs_of_eq_coincide) Verify that the two definitions of equality are equivalent.

```
Theorem two_defs_of_eq_coincide : \forall (X:Type) (x y : X), x = y \leftrightarrow x = 'y.

Proof.

Admitted.
```

The advantage of the second definition is that the induction principle that Coq derives for it is precisely the familiar principle of $Leibniz\ equality$: what we mean when we say "x and y are equal" is that every property on P that is true of x is also true of y.

```
Check eq'_ind.
```

One important consideration remains. Clearly, we can use $refl_{-}equal$ to construct evidence that, for example, 2 = 2. Can we also use it to construct evidence that 1 + 1 = 2? Yes: indeed, it is the very same piece of evidence! The reason is that Coq treats as "the same" any two terms that are *convertible* according to a simple set of computation rules. These rules, which are similar to those used by Eval simpl, include evaluation of function application, inlining of definitions, and simplification of matches.

In tactic-based proofs of equality, the conversion rules are normally hidden in uses of simpl (either explicit or implicit in other tactics such as reflexivity). But you can see them directly at work in the following explicit proof objects:

```
Definition four: 2 + 2 = 1 + 3 :=
```

```
refl_equal nat 4. 
 Definition singleton : \forall (X:Set) (x:X), []++[x] = x::[] := fun (X:Set) (x:X) \Rightarrow refl_equal (list X) [x]. 
 End MYEQUALITY.
```

8.8.1 Inversion, Again

We've seen inversion used with both equality hypotheses and hypotheses about inductively defined propositions. Now that we've seen that these are actually the same thing, we're in a position to take a closer look at how inversion behaves...

In general, the inversion tactic

- \bullet takes a hypothesis H whose type P is inductively defined, and
- for each constructor C in P's definition,
 - generates a new subgoal in which we assume H was built with C,
 - adds the arguments (premises) of C to the context of the subgoal as extra hypotheses,
 - matches the conclusion (result type) of C against the current goal and calculates a set of equalities that must hold in order for C to be applicable,
 - adds these equalities to the context (and, for convenience, rewrites them in the goal), and
 - if the equalities are not satisfiable (e.g., they involve things like S n = O), immediately solves the subgoal.

Example: If we invert a hypothesis built with or, there are two constructors, so two subgoals get generated. The conclusion (result type) of the constructor $(P \vee Q)$ doesn't place any restrictions on the form of P or Q, so we don't get any extra equalities in the context of the subgoal.

Example: If we invert a hypothesis built with and, there is only one constructor, so only one subgoal gets generated. Again, the conclusion (result type) of the constructor $(P \wedge Q)$ doesn't place any restrictions on the form of P or Q, so we don't get any extra equalities in the context of the subgoal. The constructor does have two arguments, though, and these can be seen in the context in the subgoal.

Example: If we invert a hypothesis built with eq, there is again only one constructor, so only one subgoal gets generated. Now, though, the form of the refl_equal constructor does give us some extra information: it tells us that the two arguments to eq must be the same! The inversion tactic adds this fact to the context.

8.9 Relations as Propositions

A proposition parameterized by a number (such as ev or beautiful) can be thought of as a property – i.e., it defines a subset of nat, namely those numbers for which the proposition is provable. In the same way, a two-argument proposition can be thought of as a relation – i.e., it defines a set of pairs for which the proposition is provable.

Module LEFIRSTTRY.

We've already seen an inductive definition of one fundamental relation: equality. Another useful one is the "less than or equal to" relation on numbers:

The following definition should be fairly intuitive. It says that there are two ways to give evidence that one number is less than or equal to another: either observe that they are the same number, or give evidence that the first is less than or equal to the predecessor of the second.

```
Inductive le : \operatorname{\mathsf{nat}} \to \operatorname{\mathsf{nat}} \to \operatorname{\mathsf{Prop}} := |\operatorname{\mathsf{le}}_{-n} : \forall \ n, \ \operatorname{\mathsf{le}} \ n \ n | \operatorname{\mathsf{le}}_{-S} : \forall \ n \ m, \ (\operatorname{\mathsf{le}} \ n \ m) \to (\operatorname{\mathsf{le}} \ n \ (\operatorname{\mathsf{S}} \ m)). End LeFirstTry.
```

This is a reasonable definition of the \leq relation, but we can streamline it a little by observing that the left-hand argument n is the same everywhere in the definition, so we can actually make it a "general parameter" to the whole definition, rather than an argument to each constructor. This is similar to what we did in our second definition of the eq relation, above.

```
Inductive \mathbf{le}\ (n:\mathbf{nat}): \mathbf{nat} \to \mathsf{Prop} := | \mathsf{le}_{-}\mathsf{n} : \mathsf{le}\ n\ n | \mathsf{le}_{-}\mathsf{S} : \forall\ m, \, (\mathsf{le}\ n\ m) \to (\mathsf{le}\ n\ (\mathsf{S}\ m)). Notation "\mathsf{m} <= \mathsf{n}" := (\mathsf{le}\ m\ n).
```

The second one is better, even though it looks less symmetric. Why? Because it gives us a simpler induction principle. (The same was true of our second version of eq.)

Check le_ind.

By contrast, the induction principle that Coq calculates for the first definition has a lot of extra quantifiers, which makes it messier to work with when proving things by induction. Here is the induction principle for the first le:

Proofs of facts about \leq using the constructors le_n and le_s follow the same patterns as proofs about properties, like ev in chapter Prop. We can apply the constructors to prove \leq goals (e.g., to show that 3 <= 3 or 3 <= 6), and we can use tactics like inversion to extract information from \leq hypotheses in the context (e.g., to prove that $(2 \leq 1)$.)

Here are some sanity checks on the definition. (Notice that, although these are the same kind of simple "unit tests" as we gave for the testing functions we wrote in the first few

lectures, we must construct their proofs explicitly – simpl and reflexivity don't do the job, because the proofs aren't just a matter of simplifying computations.)

```
Theorem test_le1:
  3 < 3.
Proof.
  apply le_n. Qed.
Theorem test_le2:
  3 < 6.
Proof.
  apply le_S. apply le_S. apply le_S. apply le_n. Qed.
Theorem test_le3:
  \neg (2 \le 1).
Proof.
  intros H. inversion H. inversion H1. Qed.
   The "strictly less than" relation n < m can now be defined in terms of le.
Definition It (n m: nat) := le (S n) m.
Notation "m < n" := (It m n).
   Here are a few more simple relations on numbers:
Inductive square_of : nat \rightarrow nat \rightarrow Prop :=
  sq: \forall n:nat, square\_of n (n \times n).
Inductive next_nat(n:nat) : nat \rightarrow Prop :=
  Inductive next\_even (n:nat) : nat \rightarrow Prop :=
   ne_1: ev (S n) \rightarrow next\_even n (S n)
  | ne_2 : ev (S(S n)) \rightarrow next\_even n(S(S n)).
```

Exercise: 2 stars, recommended (total_relation) Define an inductive binary relation total_relation that holds between every pair of natural numbers.

Exercise: 2 stars (empty_relation) Define an inductive binary relation *empty_relation* (on numbers) that never holds.

Exercise: 3 stars, recommended (R_provability) Module R.

We can define three-place relations, four-place relations, etc., in just the same way as binary relations. For example, consider the following three-place relation on numbers:

```
Inductive R : nat \rightarrow nat \rightarrow nat \rightarrow Prop :=
```

```
 \begin{array}{l} | \ \mathsf{c1} : \ \mathsf{R} \ 0 \ 0 \ 0 \\ | \ \mathsf{c2} : \ \forall \ m \ n \ o, \ \mathsf{R} \ m \ n \ o \to \mathsf{R} \ (\mathsf{S} \ m) \ n \ (\mathsf{S} \ o) \\ | \ \mathsf{c3} : \ \forall \ m \ n \ o, \ \mathsf{R} \ m \ n \ o \to \mathsf{R} \ m \ (\mathsf{S} \ n) \ (\mathsf{S} \ o) \\ | \ \mathsf{c4} : \ \forall \ m \ n \ o, \ \mathsf{R} \ (\mathsf{S} \ m) \ (\mathsf{S} \ n) \ (\mathsf{S} \ (\mathsf{S} \ o)) \to \mathsf{R} \ m \ n \ o \\ | \ \mathsf{c5} : \ \forall \ m \ n \ o, \ \mathsf{R} \ m \ n \ o \to \mathsf{R} \ n \ m \ o. \end{array}
```

- Which of the following propositions are provable?
 - R 1 1 2
 - R 2 2 6
- If we dropped constructor c5 from the definition of R, would the set of provable propositions change? Briefly (1 sentence) explain your answer.
- If we dropped constructor c4 from the definition of R, would the set of provable propositions change? Briefly (1 sentence) explain your answer.

Exercise: 3 stars, optional (R_{fact}) State and prove an equivalent characterization of the relation R. That is, if R m n o is true, what can we say about m, n, and o, and vice versa?

End R.

Exercise: 3 stars, recommended (all_forallb) Inductively define a property all of lists, parameterized by a type X and a property $P: X \to \mathsf{Prop}$, such that all X P l asserts that P is true for every element of the list l.

```
\texttt{Inductive all } (X : \texttt{Type}) \; (P : X \to \texttt{Prop}) : \; \textbf{list} \; X \to \texttt{Prop} := \\
```

.

Recall the function forallb, from the exercise forall_exists_challenge in chapter Poly:

```
Fixpoint forallb \{X: \mathsf{Type}\}\ (test: X \to \mathbf{bool})\ (l: \mathsf{list}\ X): \mathsf{bool} := \mathsf{match}\ l \ \mathsf{with} \mid \ [] \Rightarrow \mathsf{true} \mid x:: l' \Rightarrow \mathsf{andb}\ (test\ x)\ (\mathsf{forallb}\ test\ l') end.
```

Using the property *all*, write down a specification for *forallb*, and prove that it satisfies the specification. Try to make your specification as precise as possible.

Are there any important properties of the function *forallb* which are not captured by your specification?

Exercise: 4 stars, optional (filter_challenge) One of the main purposes of Coq is to prove that programs match their specifications. To this end, let's prove that our definition of *filter* matches a specification. Here is the specification, written out informally in English.

Suppose we have a set X, a function test: $X \rightarrow bool$, and a list l of type list X. Suppose further that l is an "in-order merge" of two lists, l1 and l2, such that every item in l1 satisfies test and no item in l2 satisfies test. Then $filter\ test\ l=l1$.

A list l is an "in-order merge" of l1 and l2 if it contains all the same elements as l1 and l2, in the same order as l1 and l2, but possibly interleaved. For example, 1,4,6,2,3 is an in-order merge of 1,6,2 and 4,3. Your job is to translate this specification into a Coq theorem and prove it. (Hint: You'll need to begin by defining what it means for one list to be a merge of two others. Do this with an inductive relation, not a Fixpoint.)

Exercise: 5 stars, optional (filter_challenge_2) A different way to formally characterize the behavior of *filter* goes like this: Among all subsequences of l with the property that test evaluates to true on all their members, filter test l is the longest. Express this claim formally and prove it.

Exercise: 4 stars, optional (no_repeats) The following inductively defined proposition...

```
Inductive appears_in \{X: \texttt{Type}\}\ (a:X): \texttt{list}\ X \to \texttt{Prop}:= | \texttt{ai\_here}: \ \forall \ l, \ \texttt{appears\_in}\ a\ (a::l) | \texttt{ai\_later}: \ \forall \ b\ l, \ \texttt{appears\_in}\ a\ l \to \texttt{appears\_in}\ a\ (b::l).
```

...gives us a precise way of saying that a value a appears at least once as a member of a list l.

Here's a pair of warm-ups about appears_in.

```
Lemma appears_in_app : \forall {X:Type} (xs ys : list X) (x:X), appears_in x (xs ++ ys) \rightarrow appears_in x xs \forall appears_in x ys. Proof.
```

Admitted.

```
Lemma app_appears_in : \forall {X:Type} (xs ys : list X) (x:X), appears_in x xs \lor appears_in x ys \to appears_in x (xs ++ ys). Proof.
```

Admitted.

Now use $appears_in$ to define a proposition $disjoint \ X \ l1 \ l2$, which should be provable exactly when l1 and l2 are lists (with elements of type X) that have no elements in common.

Next, use $appears_in$ to define an inductive proposition $no_repeats\ X\ l$, which should be provable exactly when l is a list (with elements of type X) where every member is different

from every other. For example, $no_repeats$ nat [1,2,3,4] and $no_repeats$ bool [] should be provable, while $no_repeats$ nat [1,2,1] and $no_repeats$ bool [$true_true$] should not be.

Finally, state and prove one or more interesting theorems relating disjoint, $no_repeats$ and ++ (list append).

8.9.1 Digression: More Facts about \leq and \leq

Let's pause briefly to record several facts about the \leq and < relations that we are going to need later in the course. The proofs make good practice exercises.

```
Exercise: 2 stars, optional (le_exercises) Theorem O_{-le_n} : \forall n
  0 \leq n.
Proof.
    Admitted.
Theorem n_{e_m} = Sn_{e_m} = Sm : \forall n m,
  n \leq m \rightarrow S \ n \leq S \ m.
Proof.
    Admitted.
Theorem Sn_{e}Sm_{n}=n_{e} : \forall n m,
  S n \leq S m \rightarrow n \leq m.
Proof.
  intros n m. generalize dependent n. induction m.
    Admitted.
Theorem le_plus_l : \forall a \ b,
  a \leq a + b.
Proof.
    Admitted.
Theorem plus_lt: \forall n1 \ n2 \ m,
  n1 + n2 < m \rightarrow
  n1 < m \land n2 < m.
Proof.
    Admitted.
Theorem lt_S : \forall n m,
  n < m \rightarrow
  n < S m.
Proof.
    Admitted.
Theorem ble_nat_true : \forall n m,
  ble_nat n m = true \rightarrow n \leq m.
```

```
Proof. Admitted. Theorem ble_nat_n_Sn_false: \forall n \ m, ble_nat n \ (S \ m) = false \rightarrow ble_nat n \ m = false. Proof. Admitted. Theorem ble_nat_false: \forall n \ m, ble_nat n \ m = false \rightarrow ~ (n \le m). Proof. Admitted.
```

Exercise: 3 stars, recommended (nostutter) Formulating inductive definitions of predicates is an important skill you'll need in this course. Try to solve this exercise without any help at all (except from your study group partner, if you have one).

We say that a list of numbers "stutters" if it repeats the same number consecutively. The predicate "nostutter mylist" means that mylist does not stutter. Formulate an inductive definition for nostutter. (This is different from the $no_repeats$ predicate in the exercise above; the sequence 1,4,1 repeats but does not stutter.)

```
Inductive nostutter: list nat \rightarrow Prop :=
```

Make sure each of these tests succeeds, but you are free to change the proof if the given one doesn't work for you. Your definition might be different from mine and still correct, in which case the examples might need a different proof.

The suggested proofs for the examples (in comments) use a number of tactics we haven't talked about, to try to make them robust with respect to different possible ways of defining nostutter. You should be able to just uncomment and use them as-is, but if you prefer you can also prove each example with more basic tactics.

```
Example test_nostutter_1: nostutter [3,1,4,1,5,6].

Admitted.

Example test_nostutter_2: nostutter [].

Admitted.

Example test_nostutter_3: nostutter [5].

Admitted.

Example test_nostutter_4: not (nostutter [3,1,1,4]).

Admitted.
```

Exercise: 4 stars, optional (pigeonhole principle) The "pigeonhole principle" states a basic fact about counting: if you distribute more than n items into n pigeonholes, some pigeonhole must contain at least two items. As is often the case, this apparently trivial fact about numbers requires non-trivial machinery to prove, but we now have enough...

First a pair of useful lemmas... (we already proved this for lists of naturals, but not for arbitrary lists.)

```
Lemma app_length : \forall {X:Type} (l1\ l2: list X), length (l1\ ++\ l2) = length l1\ + length l2. Proof.

Admitted.

Lemma appears_in_app_split : \forall {X:Type} (x:X) (l:list X), appears_in x\ l \rightarrow \exists\ l1, \exists\ l2, l = l1\ ++\ (x::l2).

Proof.

Admitted.
```

Now define a predicate repeats (analogous to $no_repeats$ in the exercise above), such that repeats X l asserts that l contains at least one repeated element (of type X).

```
Inductive repeats \{X: Type\}:  list X \to Prop :=
```

Now here's a way to formalize the pigeonhole principle. List l2 represents a list of pigeonhole labels, and list l1 represents an assignment of items to labels: if there are more items than labels, at least two items must have the same label. You will almost certainly need to use the $excluded_middle$ hypothesis.

```
Theorem pigeonhole_principle: \forall \{X: \texttt{Type}\}\ (l1\ l2: \texttt{list}\ X), excluded_middle \rightarrow (\forall x, \texttt{appears\_in}\ x\ l1 \rightarrow \texttt{appears\_in}\ x\ l2) \rightarrow length l2 < \texttt{length}\ l1 \rightarrow repeats l1. Proof. intros X\ l1. induction l1. Admitted.
```

8.10 Informal Proofs

Q: What is the relation between a formal proof of a proposition P and an informal proof of the same proposition P?

A: The latter should *teach* the reader how to produce the former.

Q: How much detail is needed?

A: There is no single right answer; rather, there is a range of choices.

At one end of the spectrum, we can essentially give the reader the whole formal proof (i.e., the informal proof amounts to just transcribing the formal one into words). This gives the reader the *ability* to reproduce the formal one for themselves, but it doesn't *teach* them anything.

At the other end of the spectrum, we can say "The theorem is true and you can figure out why for yourself if you think about it hard enough." This is also not a good teaching strategy, because usually writing the proof requires some deep insights into the thing we're proving, and most readers will give up before they rediscover all the same insights as we did.

In the middle is the golden mean – a proof that includes all of the essential insights (saving the reader the hard part of work that we went through to find the proof in the first place) and clear high-level suggestions for the more routine parts to save the reader from spending too much time reconstructing these parts (e.g., what the IH says and what must be shown in each case of an inductive proof), but not so much detail that the main ideas are obscured.

Another key point: if we're talking about a formal proof of a proposition P and an informal proof of P, the proposition P doesn't change. That is, formal and informal proofs are talking about the same world and they must play by the same rules.

8.10.1 Informal Proofs by Induction

Since we've spent much of this chapter looking "under the hood" at formal proofs by induction, now is a good moment to talk a little about *informal* proofs by induction.

In the real world of mathematical communication, written proofs range from extremely longwinded and pedantic to extremely brief and telegraphic. The ideal is somewhere in between, of course, but while you are getting used to the style it is better to start out at the pedantic end. Also, during the learning phase, it is probably helpful to have a clear standard to compare against. With this in mind, we offer two templates below – one for proofs by induction over *data* (i.e., where the thing we're doing induction on lives in Type) and one for proofs by induction over *evidence* (i.e., where the inductively defined thing lives in Prop). In the rest of this course, please follow one of the two for *all* of your inductive proofs.

Induction Over an Inductively Defined Set

Template:

• Theorem: <Universally quantified proposition of the form "For all n:S, P(n)," where S is some inductively defined set.>

Proof: By induction on n.

<one case for each constructor c of S...>

- Suppose n = c a1 ... ak, where <...and here we state the IH for each of the a's that has type S, if any>. We must show <...and here we restate $P(c \ a1 \ ... \ ak)>$. <go on and prove P(n) to finish the case...>

– <other cases="" similarly=""> \square</other>	
Example:	
• Theorem: For all sets X , lists l : list X , and numbers n , if length $l=n$ n) $l=None$.	then index (S
Proof: By induction on l .	
– Suppose $l = []$. We must show, for all numbers n , that, if lengt $index\ (S\ n)\ [] = None$.	[h] = n, then
This follows immediately from the definition of index.	
- Suppose $l = x :: l'$ for some x and l' , where $length \ l' = n'$ implie $l' = None$, for any number n' . We must show, for all n , that, if $length$ then $index \ (S \ n) \ (x::l') = None$.	
Let n be a number with $length \ l = n$. Since length $l = length$ (x:: l'), it suffices to show that index (S (length l')) l' = None.	l') = S (length)
But this follows directly from the induction hypothesis, picking n' to be left	ngth l' . \square
Induction Over an Inductively Defined Proposition	
Since inductively defined proof objects are often called "derivation trees," this is also known as induction on derivations. Template:	s form of proof
• Theorem: <proposition "<math="" form="" of="" the="">Q \to P," where Q is some induproposition (more generally, "For all x y z, Q x y $z \to P$ x y z")></proposition>	ctively defined
<i>Proof</i> : By induction on a derivation of Q . $<$ Or, more generally, "Suppose x , y , and z . We show that Q x y z implies P x y z , by induction on a x y z " $>$	_
<one case for each constructor c of $Q>$	
- Suppose the final rule used to show Q is c . Then <and <math="" all="" here="" of="" so="" the="" we="">a's together with any equalities that follow from the d constructor and the IH for each of the a's that has type Q, if there must show <and <math="" here="" restate="" we="">P>.</and></and>	efinition of the
<go on and prove P to finish the case $>$	
$-$ <other cases="" similarly=""> \square</other>	
Example	

• Theorem: The \leq relation is transitive – i.e., for all numbers n, m, and o, if $n \leq m$ and $m \leq o$, then $n \leq o$.

Proof: By induction on a derivation of $m \leq o$.

- Suppose the final rule used to show $m \leq o$ is le_n . Then m = o and we must show that $n \leq m$, which is immediate by hypothesis.
- Suppose the final rule used to show $m \leq o$ is le_S . Then o = S o' for some o' with $m \leq o$ '. We must show that $n \leq S$ o'. By induction hypothesis, $n \leq o$ '. But then, by le_S , $n \leq S$ o'. \square

8.11 Optional Material

8.11.1 Induction Principles for \wedge and \vee

The induction principles for conjunction and disjunction are a good illustration of Coq's way of generating simplified induction principles for Inductively defined propositions, which we discussed in the last chapter. You try first:

Exercise: 1 star, optional (and_ind_principle) See if you can predict the induction principle for conjunction.

Exercise: 1 star, optional (or_ind_principle) See if you can predict the induction principle for disjunction.

Check and_ind.

From the inductive definition of the proposition and P Q Inductive and (P Q : Prop): Prop := conj : P -> Q -> (and P Q). we might expect Coq to generate this induction principle and_ind_max : forall (P Q : Prop) (P Q -> Prop), (forall (P Q : Prop) (P Q -> Prop), (forall (P Q : Prop) (P Q -> Prop), (forall (P Q : Prop) (P Q -> Prop) (P -> P Prop): $Prop := | or_introl : <math>P$ -> or P P | Prop or P P | Prop or P Prop (P -> Prop), (forall P P Prop) (P : P -> Prop), (forall P P P Prop) (P -> P Prop) (P -> Prop) (P -

8.11.2 Explicit Proof Objects for Induction

Although tactic-based proofs are normally much easier to work with, the ability to write a proof term directly is sometimes very handy, particularly when we want Coq to do something slightly non-standard.

Recall the induction principle on naturals that Coq generates for us automatically from the Inductive declation for nat.

There's nothing magic about this induction lemma: it's just another Coq lemma that requires a proof. Coq generates the proof automatically too...

Print nat_ind.

We can read this as follows: Suppose we have evidence f that P holds on 0, and evidence f0 that $\forall n:nat$, P $n \to P$ (S n). Then we can prove that P holds of an arbitrary nat n via a recursive function F (here defined using the expression form Fix rather than by a top-level Fixpoint declaration). F pattern matches on n:

- If it finds 0, F uses f to show that P n holds.
- If it finds S $n\theta$, F applies itself recursively on $n\theta$ to obtain evidence that P $n\theta$ holds; then it applies $f\theta$ on that evidence to show that P (S n) holds.

F is just an ordinary recursive function that happens to operate on evidence in Prop rather than on terms in Set.

Aside to those interested in functional programming: You may notice that the match in F requires an annotation as $n\theta$ return $(P \ n\theta)$ to help Coq's typechecker realize that the two arms of the match actually return the same type (namely $P \ n$). This is essentially like matching over a GADT (generalized algebraic datatype) in Haskell. In fact, F has a dependent type: its result type depends on its argument; GADT's can be used to describe simple dependent types like this.

We can adapt this approach to proving nat_ind to help prove non-standard induction principles too. Recall our desire to prove that

```
\forall n : nat, even n \rightarrow ev n.
```

Attempts to do this by standard induction on n fail, because the induction principle only lets us proceed when we can prove that $even\ n \to even\ (S\ n)$ – which is of course never provable. What we did earlier in this chapter was a bit of a hack:

```
Theorem even_{-}ev : \forall n : nat, (even n \rightarrow ev n) \land (even (S n) \rightarrow ev (S n)).
```

We can make a much better proof by defining and proving a non-standard induction principle that goes "by twos":

Definition nat_ind2:

```
\forall (P: \mathsf{nat} \to \mathsf{Prop}),
P \ 0 \to
P \ 1 \to
(\forall \ n: \mathsf{nat}, P \ n \to P \ (\mathsf{S}(\mathsf{S} \ n))) \to
```

```
\begin{array}{l} \forall \; n: \, \mathbf{nat} \;, \; P \; n:= \\ & \text{fun} \; P \Rightarrow \text{fun} \; P0 \Rightarrow \text{fun} \; P1 \Rightarrow \text{fun} \; PSS \Rightarrow \\ & \text{fix} \; f \; (n: \mathbf{nat}) := \text{match} \; n \; \text{return} \; P \; n \; \text{with} \\ & 0 \Rightarrow P0 \\ & \mid 1 \Rightarrow P1 \\ & \mid \mathbf{S} \; (\mathbf{S} \; n') \Rightarrow PSS \; n' \; (f \; n') \\ & \text{end.} \end{array}
```

Once you get the hang of it, it is entirely straightforward to give an explicit proof term for induction principles like this. Proving this as a lemma using tactics is much less intuitive (try it!).

The induction ... using tactic gives a convenient way to specify a non-standard induction principle like this.

```
Lemma even__ev': \forall n, even n \to \mathbf{ev} \ n.

Proof.

intros.

induction n as [ \ | \ | n'] using nat_ind2.

Case "even 0".

apply ev_0.

Case "even 1".

inversion H.

Case "even (S(S \ n'))".

apply ev_SS.

apply IHn'. unfold even. unfold even in H. simpl in H. apply H.

Qed.
```

8.11.3 The Coq Trusted Computing Base

One issue that arises with any automated proof assistant is "why trust it?": what if there is a bug in the implementation that renders all its reasoning suspect?

While it is impossible to allay such concerns completely, the fact that Coq is based on the Curry-Howard Correspondence gives it a strong foundation. Because propositions are just types and proofs are just terms, checking that an alleged proof of a proposition is valid just amounts to type-checking the term. Type checkers are relatively small and straightforward programs, so the "trusted computing base" for Coq – the part of the code that we have to believe is operating correctly – is small too.

What must a typechecker do? Its primary job is to make sure that in each function application the expected and actual argument types match, that the arms of a match expression are constructor patterns belonging to the inductive type being matched over and all arms of the match return the same type, and so on.

There are a few additional wrinkles:

• Since Coq types can themselves be expressions, the checker must normalize these (by using the conversion rules) before comparing them.

- The checker must make sure that match expressions are *exhaustive*. That is, there must be an arm for every possible constructor. To see why, consider the following alleged proof object: Definition or_bogus: forall P Q, P \/ Q -> P := fun (P Q: Prop) (A: P \/ Q) => match A with | or_introl H => H end. All the types here match correctly, but the match only considers one of the possible constructors for *or*. Coq's exhaustiveness check will reject this definition.
- The checker must make sure that each fix expression terminates. It does this using a syntactic check to make sure that each recursive call is on a subexpression of the original argument. To see why this is essential, consider this alleged proof: Definition nat_false: forall (n:nat), False:= fix f (n:nat): False:= f n. Again, this is perfectly well-typed, but (fortunately) Coq will reject it.

Note that the soundness of Coq depends only on the correctness of this typechecking engine, not on the tactic machinery. If there is a bug in a tactic implementation (and this certainly does happen!), that tactic might construct an invalid proof term. But when you type Qed, Coq checks the term for validity from scratch. Only lemmas whose proofs pass the type-checker can be used in further proof developments.

Chapter 9

Library SfLib

9.1 SfLib: Software Foundations Library

Here we collect together several useful definitions and theorems from Basics.v, List.v, Poly.v, Ind.v, and Logic.v that are not already in the Coq standard library. From now on we can Import or Export this file, instead of cluttering our environment with all the examples and false starts in those files.

9.2 From the Coq Standard Library

```
Require Omega. Require Export Bool.
Require Export List.
Require Export Arith.
Require Export Arith.EqNat.
```

9.3 From Basics.v

```

Tactic Notation "solve" "by" "inversion" := solve\_by\_inversion\_step (solve by inversion" := solve\_by\_inversion 1.
```

Chapter 10

Library Imp

10.1 Imp: Simple Imperative Programs

In this chapter, we begin a new direction that will continue for the rest of the course. Up to now we've been mostly studying Coq itself, but from now on we'll mostly be using Coq to formalize other things.

Our first case study is a *simple imperative programming language* called Imp. Here is a familiar mathematical function written in Imp. Z ::= X; Y ::= 1; WHILE not (Z = 0) DO Y ::= Y * Z; Z ::= Z - 1 END

This chapter looks at how to define the *syntax* and *semantics* of Imp; the chapters that follow develop a theory of *program equivalence* and introduce *Hoare Logic*, the best-known logic for reasoning about imperative programs.

Sflib

A minor technical point: Instead of asking Coq to import our earlier definitions from chapter Logic, we import a small library called Sflib.v, containing just a few definitions and theorems from earlier chapters that we'll actually use in the rest of the course. This change should be nearly invisible, since most of what's missing from Sflib has identical definitions in the Coq standard library. The main reason for doing it is to tidy the global Coq environment so that, for example, it is easier to search for relevant theorems.

Require Export SfLib.

10.2 Arithmetic and Boolean Expressions

We'll present Imp in three parts: first a core language of arithmetic and boolean expressions, then an extension of these expressions with variables, and finally a language of commands including assignment, conditions, sequencing, and loops.

10.2.1 Syntax

Module AEXP.

These two definitions specify the abstract syntax of arithmetic and boolean expressions.

```
Inductive aexp: Type:= |ANum: nat \rightarrow aexp |APlus: aexp \rightarrow aexp \rightarrow aexp |AMinus: aexp \rightarrow aexp \rightarrow aexp |AMult: aexp \rightarrow aexp \rightarrow aexp |AMult: aexp \rightarrow aexp \rightarrow aexp.
Inductive bexp: Type:= |BTrue: bexp |BFalse: bexp |BFalse: bexp |BEq: aexp \rightarrow aexp \rightarrow bexp |BLe: aexp \rightarrow aexp \rightarrow bexp |BNot: bexp \rightarrow bexp |BNot: bexp \rightarrow bexp |BAnd: bexp \rightarrow bexp \rightarrow bexp.
```

In this chapter, we'll elide the translation from the concrete syntax that a programmer would actually write to these abstract syntax trees – the process that, for example, would translate the string "1+2*3" to the AST APlus (ANum 1) (AMult (ANum 2) (ANum 3)). The optional chapter ImpParser develops a simple implementation of a lexical analyzer and parser that can perform this translation. You do not need to understand that file to understand this one, but if you haven't taken a course where these techniques are covered (e.g., a compilers course) you may want to skim it.

For comparison, here's a conventional BNF (Backus-Naur Form) grammar defining the same abstract syntax: aexp ::= nat | aexp '+' aexp | aexp '-' aexp | aexp '*' aexp

bexp ::= true | false | aexp '=' aexp | aexp '<=' aexp | bexp 'and' bexp | 'not' bexp Compared to the Coq version above...

• The BNF is more informal – for example, it gives some suggestions about the surface syntax of expressions (like the fact that the addition operation is written + and is an infix symbol) while leaving other aspects of lexical analysis and parsing (like the relative precedence of +, -, and ×) unspecified. Some additional information – and human intelligence – would be required to turn this description into a formal definition (when implementing a compiler, for example).

The Coq version consistently omits all this information and concentrates on the abstract syntax only.

• On the other hand, the BNF version is lighter and easier to read. Its informality makes it flexible, which is a huge advantage in situations like discussions at the blackboard, where conveying general ideas is more important than getting every detail nailed down precisely.

Indeed, there are dozens of BNF-like notations and people switch freely among them, usually without bothering to say which form of BNF they're using because there is no need to: a rough-and-ready informal understanding is all that's needed.

It's good to be comfortable with both sorts of notations: informal ones for communicating between humans and formal ones for carrying out implementations and proofs.

10.2.2 Evaluation

Evaluating an arithmetic expression produces a number.

```
Fixpoint aeval (e : aexp) : nat :=
  match e with
    ANum n \Rightarrow n
    APlus a1 \ a2 \Rightarrow (aeval \ a1) + (aeval \ a2)
    AMinus a1 a2 \Rightarrow (aeval a1) - (aeval a2)
   AMult a1 \ a2 \Rightarrow (aeval a1) \times (aeval a2)
  end.
Example test_aeval1:
  aeval (APlus (ANum 2) (ANum 2)) = 4.
Proof. reflexivity. Qed.
    Similarly, evaluating a boolean expression yields a boolean.
Fixpoint beval (e : \mathbf{bexp}) : \mathbf{bool} :=
  match e with
    BTrue \Rightarrow true
    BFalse \Rightarrow false
    BEq a1 a2 \Rightarrow beg_nat (aeval a1) (aeval a2)
    BLe a1 a2 \Rightarrow ble_nat (aeval a1) (aeval a2)
    BNot b1 \Rightarrow \text{negb} (beval b1)
   | BAnd b1 b2 \Rightarrow andb (beval b1) (beval b2)
  end.
```

10.2.3 Optimization

We haven't defined very much yet, but we can already get some mileage out of the definitions. Suppose we define a function that takes an arithmetic expression and slightly simplifies it, changing every occurrence of 0+e (i.e., $(APlus\ (ANum\ 0)\ e)$ into just e.

```
Fixpoint optimize_0plus (e:aexp): aexp:= match e with | ANum n \Rightarrow ANum n | APlus (ANum 0) e2 \Rightarrow
```

```
optimize_Oplus e2
  | APlus e1 \ e2 \Rightarrow
      APlus (optimize_0plus e1) (optimize_0plus e2)
  | AMinus e1 \ e2 \Rightarrow
      AMinus (optimize_0plus e1) (optimize_0plus e2)
  | AMult e1 \ e2 \Rightarrow
      AMult (optimize_0plus e1) (optimize_0plus e2)
  end.
   To make sure our optimization is doing the right thing we can test it on some examples
and see if the output looks OK.
Example test_optimize_Oplus:
  optimize_Oplus (APlus (ANum 2)
                           (APlus (ANum 0)
                                  (APlus (ANum 0) (ANum 1))))
  = APlus (ANum 2) (ANum 1).
Proof. reflexivity. Qed.
   But if we want to be sure the optimization is correct – i.e., that evaluating an optimized
expression gives the same result as the original – we should prove it.
Theorem optimize_0plus_sound: \forall e,
  aeval (optimize_0plus e) = aeval e.
Proof.
  intros e. induction e.
  Case "ANum". reflexivity.
  Case "APlus". destruct e1.
    SCase "e1 = ANum n". destruct n.
      SSCase "n = 0". simpl. apply IHe2.
      SSCase "n <> 0". simpl. rewrite IHe2. reflexivity.
    SCase "e1 = APlus e1_1 e1_2".
      simpl. simpl in IHe1. rewrite IHe1.
      rewrite IHe2. reflexivity.
    SCase "e1 = AMinus e1_1 e1_2".
      simpl. simpl in IHe1. rewrite IHe1.
      rewrite IHe2. reflexivity.
    SCase "e1 = AMult e1_1 e1_2".
      simpl. simpl in IHe1. rewrite IHe1.
      rewrite IHe2. reflexivity.
  Case "AMinus".
    simpl. rewrite IHe1. rewrite IHe2. reflexivity.
  Case "AMult".
    simpl. rewrite IHe1. rewrite IHe2. reflexivity. Qed.
```

10.3 Coq Automation

The repetition in this last proof is starting to be a little annoying. If either the language of arithmetic expressions or the optimization being proved sound were significantly more complex, it would begin to be a real problem.

So far, we've been doing all our proofs using just a small handful of Coq's tactics and completely ignoring its powerful facilities for constructing parts of proofs automatically. This section introduces some of these facilities, and we will see more over the next several chapters. Getting used to them will take some energy – Coq's automation is a power tool – but it will allow us to scale up our efforts to more complex definitions and more interesting properties without becoming overwhelmed by boring, repetitive, low-level details.

10.3.1 Tacticals

Tacticals is Coq's term for tactics that take other tactics as arguments – "higher-order tactics," if you will.

The repeat Tactical

Theorem ev100': ev 100.

The repeat tactical takes another tactic and keeps applying this tactic until the tactic fails. Here is an example showing that 100 is even using repeat.

```
Theorem ev100 : ev 100.

Proof.

repeat (apply ev_SS). apply ev_0.

Qed.
```

The repeat T tactic never fails; if the tactic T doesn't apply to the original goal, then repeat still succeeds without changing the original goal (it repeats zero times).

```
Proof.
repeat (apply ev_0). repeat (apply ev_SS). apply ev_0. Qed.
```

The repeat T tactic does not have any bound on the number of times it applies T. If T is a tactic that always succeeds then repeat T will loop forever (e.g. repeat simpl loops forever since simpl always succeeds). While Coq's term language is guaranteed to terminate, Coq's tactic language is not.

The try Tactical

A similar tactical is try: If T is a tactic, then try T is a tactic that is just like T except that, if T fails, try T successfully does nothing at all (instead of failing).

```
Theorem silly1 : \forall ae, aeval ae = aeval ae.
Proof. try reflexivity. Qed.
Theorem silly2 : \forall (P : Prop), P \rightarrow P.
```

```
Proof.
  intros P HP.
  try reflexivity.
                      apply HP. Qed.
```

Using try in a completely manual proof is a bit silly, but we'll see below that try is very useful for doing automated proofs in conjunction with the; tactical.

The; Tactical (Simple Form)

In its simplest and most commonly used form, the ; tactical takes 2 tactics as argument: T;T' first performs the tactic T and then performs the tactic T' on each subgoal generated by T.

```
For example, consider the following trivial lemma:
Lemma foo : \forall n, ble_nat 0 n = \text{true}.
Proof.
  intros.
  destruct n.
    Case "n=0". simpl. reflexivity.
    Case "n=Sn'". simpl. reflexivity.
Qed.
   We can simplify this proof using the; tactical:
Lemma foo' : \forall n, ble_nat 0 n = \text{true}.
Proof.
  intros.
  destruct n;
  simpl;
  reflexivity. Qed.
   Using try and; together, we can get rid of the repetition in the proof that was bothering
us a little while ago.
Theorem optimize_Oplus_sound': \forall e,
  aeval (optimize_0plus e) = aeval e.
Proof.
  intros e.
  induction e;
    try (simpl; rewrite IHe1; rewrite IHe2; reflexivity).
  Case "ANum". reflexivity.
  Case "APlus".
    destruct e1;
      try (simpl; simpl in IHe1; rewrite IHe1;
```

rewrite IHe2; reflexivity).

```
SCase "e1 = ANum n". destruct n; simpl; rewrite IHe2; reflexivity. Qed.
```

Coq experts often use this "...; try..." idiom after a tactic like induction to take care of many similar cases all at once. Naturally, this practice has an analog in informal proofs. Here is an informal proof of this theorem that matches the structure of the formal one:

Theorem: For all arithmetic expressions e, aeval (optimize_0plus e) = aeval e. Proof: By induction on e. The AMinus and AMult cases follow directly from the IH. The remaining cases are as follows:

- Suppose $e = ANum \ n$ for some n. We must show aeval (optimize_0plus (ANum n)) = aeval (ANum n). This is immediate from the definition of optimize_0plus.
- Suppose $e = APlus\ e1\ e2$ for some e1 and e2. We must show aeval (optimize_0plus (APlus e1 e2)) = aeval (APlus e1 e2). Consider the possible forms of e1. For most of them, $optimize_0plus$ simply calls itself recursively for the subexpressions and rebuilds a new expression of the same form as e1; in these cases, the result follows directly from the IH.

The interesting case is when $e1 = ANum \ n$ for some n. If $n = ANum \ 0$, then optimize_0plus (APlus e1 e2) = optimize_0plus e2 and the IH for e2 is exactly what we need. On the other hand, if $n = S \ n'$ for some n', then again $optimize_0plus$ simply calls itself recursively, and the result follows from the IH. \square

This proof can still be improved: the first case (for $e = ANum\ n$) is very trivial – even more trivial than the cases that we said simply followed from the IH – yet we have chosen to write it out in full. It would be better and clearer to drop it and just say, at the top, "Most cases are either immediate or direct from the IH. The only interesting case is the one for APlus..." We can make the same improvement in our formal proof too. Here's how it looks:

The; Tactical (General Form)

The ; tactical has a more general than the simple T; T' we've seen above, and which is sometimes also useful. If T, T1, ..., Tn are tactics, then $T; T1 \mid T2 \mid ... \mid Tn$ is a tactic that first performs T and then performs T1 on the first subgoal generated by T, performs T2 on the second subgoal, etc.

So T; T' is just special notation for the case when all of the Ti's are the same tactic; i.e. T; T' is just a shorthand for: $T; T' \mid T' \mid \dots \mid T'$ The form T; T' is used most often in practice.

10.3.2 Defining New Tactic Notations

Coq also provides several ways of "programming" tactic scripts.

- The Tactic Notation idiom illustrated below gives a handy way to define "shorthand tactics" that bundle several tactics into a single command.
- For more sophisticated programming, Coq offers a small built-in programming language called Ltac with primitives that can examine and modify the proof state. The details are a bit too complicated to get into here (and it is generally agreed that Ltac is not the most beautiful part of Coq's design!), but they can be found in the reference manual, and there are many examples of Ltac definitions in the Coq standard library that you can use as examples.
- There is also an OCaml API, which can be used to build tactics that access Coq's internal structures at a lower level, but this is seldom worth the trouble for ordinary Coq users.

The Tactic Notation mechanism is the easiest to come to grips with, and it offers plenty of power for many purposes. Here's an example.

```
Tactic Notation "simpl_and_try" tactic(c) := simpl; try c.
```

This defines a new tactical called $simpl_and_try$ which takes one tactic c as an argument, and is defined to be equivalent to the tactic simpl; try c. For example, writing " $simpl_and_try$ reflexivity." in a proof would be the same as writing "simpl; try reflexivity."

The next subsection gives a more sophisticated use of this feature...

Bulletproofing Case Analyses

Being able to deal with most of the cases of an induction or destruct all at the same time is very convenient, but it can also be a little confusing. One problem that often comes up is that *maintaining* proofs written in this style can be difficult. For example, suppose

that, later, we extended the definition of aexp with another constructor that also required a special argument. The above proof might break because Coq generated the subgoals for this constructor before the one for APlus, so that, at the point when we start working on the APlus case, Coq is actually expecting the argument for a completely different constructor. What we'd like is to get a sensible error message saying "I was expecting the AFoo case at this point, but the proof script is talking about APlus." Here's a nice trick (due to Aaron Bohannon) that smoothly achieves this.

```
Tactic Notation "aexp_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c "ANum" | Case\_aux \ c "APlus" | Case\_aux \ c "AMinus" | Case\_aux \ c "AMult" ].
```

(Case_aux implements the common functionality of Case, SCase, SSCase, etc. For example, Case "foo" is defined as Case_aux Case "foo".)

For example, if e is a variable of type aexp, then doing $aexp_cases$ (induction e) Case will perform an induction on e (the same as if we had just typed induction e) and also add a Case tag to each subgoal generated by the induction, labeling which constructor it comes from. For example, here is yet another proof of $optimize_0plus_sound$, using $aexp_cases$:

```
Theorem optimize_Oplus_sound''': \( \forall e, \)
aeval (optimize_Oplus e) = aeval e.

Proof.
intros e.
aexp_cases (induction e) Case;
try (simpl; rewrite IHe1; rewrite IHe2; reflexivity);
try reflexivity.
Case "APlus".
aexp_cases (destruct e1) SCase;
try (simpl; simpl in IHe1; rewrite IHe1; rewrite IHe2; reflexivity).
SCase "ANum". destruct n;
simpl; rewrite IHe2; reflexivity. Qed.
```

Exercise: 3 stars (optimize_Oplus_b) Since the *optimize_Oplus* tranformation doesn't change the value of *aexp*s, we should be able to apply it to all the *aexp*s that appear in a *bexp* without changing the *bexp*'s value. Write a function which performs that transformation on *bexp*s, and prove it is sound. Use the tacticals we've just seen to make the proof as elegant as possible.

Exercise: 4 stars, optional (optimizer) Design exercise: The optimization implemented by our optimize_0plus function is only one of many imaginable optimizations on arithmetic and boolean expressions. Write a more sophisticated optimizer and prove it correct.

10.3.3 The omega Tactic

The omega tactic implements a decision procedure for a subset of first-order logic called *Presburger arithmetic*. It is based on the Omega algorithm invented in 1992 by William Pugh.

If the goal is a universally quantified formula made out of

- numeric constants, addition (+ and S), subtraction (- and pred), and multiplication by constants (this is what makes it Presburger arithmetic),
- equality (= and \neq) and inequality (\leq), and
- the logical connectives \land , \lor , \neg , and \rightarrow ,

then invoking omega will either solve the goal or tell you that it is actually false.

```
Example silly_presburger_example : \forall m \ n \ o \ p, m+n \leq n+o \land o+3=p+3 \rightarrow m \leq p.

Proof.
intros. omega.
Qed.
```

Andrew Appel calls this the "Santa Claus tactic." We'll see examples of its use below.

10.3.4 A Few More Handy Tactics

Finally, here are some miscellaneous tactics that you may find convenient.

- clear H: Delete hypothesis H from the context.
- subst x: Find an assumption x = e or e = x in the context, replace x with e throughout the context and current goal, and clear the assumption.
- subst: Substitute away all assumptions of the form x = e or e = x.
- rename... into...: Change the name of a hypothesis in the proof context. For example, if the context includes a variable named x, then rename x into y will change all occurrences of x to y.
- assumption: Try to find a hypothesis *H* in the context that exactly matches the goal; if one is found, behave just like apply *H*.
- contradiction: Try to find a hypothesis H in the current context that is logically equivalent to False. If one is found, solve the goal.

• constructor: Try to find a constructor c (from some Inductive definition in the current environment) that can be applied to solve the current goal. If one is found, behave like apply c.

We'll see many examples of these in the proofs below.

10.4 Evaluation as a Relation

We have presented *aeval* and *beval* as functions defined by *Fixpoints*. Another way to think about evaluation, one that we will see is often more flexible, is as a *relation* between expressions and their values. This leads naturally to **Inductive** definitions like the following one for arithmetic expressions...

Module AEVALR_FIRST_TRY.

As is often the case with relations, we'll find it convenient to define infix notation for aevalR. We'll write $e \mid\mid n$ to mean that arithmetic expression e evaluates to value n. (This notation is one place where the limitation to ASCII symbols becomes a little bothersome. The standard notation for the evaluation relation is a double down-arrow. We'll typeset it like this in the HTML version of the notes and use a double vertical bar as the closest approximation in v files.)

```
Notation "e'||' n" := (aevalR e n) : type\_scope.
End AEVALR_FIRST_TRY.
```

In fact, Coq provides a way to use this notation in the definition of aevalR itself. This avoids situations where we're working on a proof involving statements in the form $e \mid\mid n$ but we have to refer back to a definition written using the form aevalR e n.

We do this by first "reserving" the notation, then giving the definition together with a declaration of what the notation means.

```
Reserved Notation "e' | 'n" (at level 50, left associativity).
Inductive aevalR : aexp \rightarrow nat \rightarrow Prop :=
  \mid \mathsf{E\_ANum} : \forall (n:\mathsf{nat}),
        (ANum n) \mid \mid n
  \mid \mathsf{E\_APlus} : \forall \ (e1 \ e2 : \mathbf{aexp}) \ (n1 \ n2 : \mathbf{nat}),
        (e1 \mid \mid n1) \rightarrow (e2 \mid \mid n2) \rightarrow (APlus \ e1 \ e2) \mid \mid (n1 + n2)
  \mid \mathsf{E\_AMinus} : \forall \ (e1 \ e2 : \mathsf{aexp}) \ (n1 \ n2 : \mathsf{nat}),
        (e1 \mid \mid n1) \rightarrow (e2 \mid \mid n2) \rightarrow (AMinus e1 e2) \mid \mid (n1 - n2)
  \mid \mathsf{E\_AMult} : \forall \ (e1 \ e2 : \mathsf{aexp}) \ (n1 \ n2 : \mathsf{nat}),
        (e1 \mid \mid n1) \rightarrow (e2 \mid \mid n2) \rightarrow (\mathsf{AMult} \ e1 \ e2) \mid \mid (n1 \times n2)
  where "e'||' n" := (aevalR e n) : type\_scope.
Tactic Notation "aevalR_cases" tactic(first) ident(c) :=
  first;
  [ Case_aux c "E_ANum" | Case_aux c "E_APlus"
  | Case_aux c "E_AMinus" | Case_aux c "E_AMult" ].
    It is straightforward to prove that the relational and functional definitions of evaluation
agree on all possible arithmetic expressions...
Theorem aeval_iff_aevalR : \forall a \ n,
   (a \mid \mid n) \leftrightarrow \text{aeval } a = n.
Proof.
 split.
 Case "->".
    intros H.
    aevalR\_cases (induction H) SCase; simpl.
    SCase "E_ANum".
      reflexivity.
    SCase "E_APlus".
      rewrite IHaevalR1. rewrite IHaevalR2. reflexivity.
    SCase "E_AMinus".
      rewrite IHaevalR1. rewrite IHaevalR2. reflexivity.
    SCase "E_AMult".
      rewrite IHaevalR1. rewrite IHaevalR2. reflexivity.
 Case "<-".
    generalize dependent n.
    aexp_cases (induction a) SCase;
        simpl; intros; subst.
    SCase "ANum".
       apply E_ANum.
    SCase "APlus".
       apply E_APlus.
```

```
apply IHa1. reflexivity.
apply IHa2. reflexivity.
SCase "AMinus".
apply E_AMinus.
apply IHa1. reflexivity.
apply IHa2. reflexivity.
SCase "AMult".
apply E_AMult.
apply E_AMult.
apply IHa1. reflexivity.
apply IHa2. reflexivity.
Qed.
```

We can make the proof quite a bit shorter by making more aggressive use of tacticals...

```
Theorem aeval_iff_aevalR': \forall a \ n, (a \mid \mid n) \leftrightarrow \text{aeval } a = n.

Proof.

split.

Case \text{"->"}.

intros H; induction H; subst; reflexivity.

Case \text{"<-"}.

generalize dependent n.

induction a; simpl; intros; subst; constructor; try apply IHa1; try apply IHa2; reflexivity.

Qed.
```

Exercise: 3 stars (bevalR) Write a relation bevalR in the same style as aevalR, and prove that it is equivalent to beval.

For the definitions of evaluation for arithmetic and boolean expressions, the choice of whether to use functional or relational definitions is mainly a matter of taste. In general, Coq has somewhat better support for working with relations. On the other hand, in some sense function definitions carry more information, because functions are necessarily deterministic and defined on all arguments; for a relation we have to show these properties explicitly if we need them. Functions also take advantage of Coq's computational mechanism.

However, there are circumstances where relational definitions of evaluation are greatly preferable to functional ones, as we'll see shortly.

10.4.1 Inference Rule Notation

In informal discussions, it is convenient write the rules for aevalR and similar relations in the more readable "graphical" form of inference rules, where the premises above the line justify the conclusion below the line. For example, the constructor $E_APlus...$ | E_APlus : for all

(e1 e2: aexp) (n1 n2: nat), aevalR e1 n1 -> aevalR e2 n2 -> aevalR (APlus e1 e2) (n1 + n2) ...would be written like this as an inference rule: e1 \parallel n1 e2 \parallel n2

(E_APlus) APlus e1 e2 || n1+n2 Formally, there is nothing very deep about inference rules: they are just implications. You can read the rule name on the right as the name of the constructor and read each of the linebreaks between the premises above the line and the line itself as \rightarrow . All the variables mentioned in the rule (e1, n1, etc.) are implicitly bound by universal quantifiers at the beginning. The whole collection of rules is understood as being wrapped in an Inductive declaration (informally, this is either elided or else indicated by saying something like "Let aevalR be the smallest relation closed under the following rules...").

For example, || is the smallest relation closed under these rules:

```
(E_ANum) ANum n || n
e1 || n1 e2 || n2

(E_APlus) APlus e1 e2 || n1+n2
e1 || n1 e2 || n2

(E_AMinus) AMinus e1 e2 || n1-n2
e1 || n1 e2 || n2

(E_AMult) AMult e1 e2 || n1*n2
```

End AEXP.

10.5 Expressions With Variables

Let's turn our attention back to defining Imp. The next thing we need to do is to enrich our arithmetic and boolean expressions with variables. To keep things simple, we'll assume that all variables are global and that they only hold numbers.

10.5.1 Identifiers

To begin, we'll need to formalize *identifiers* such as program variables. We could use strings for this – or, in a real compiler, fancier structures like pointers into a symbol table. But for simplicity let's just use natural numbers as identifiers.

(We hide this section in a module because these definitions are actually in SfLib, but we want to repeat them here so that we can explain them.)

Module ID.

We define a new inductive datatype Id so that we won't confuse identifiers and numbers.

```
Inductive id: Type := Id : nat \rightarrow id.
```

```
Definition beq_id X1 \ X2 := match (X1, X2) with (Id \ n1, Id \ n2) \Rightarrow beq_nat \ n1 \ n2 end.
```

After we "wrap" numbers as identifiers in this way, it is convenient to recapitulate a few properties of numbers as analogous properties of identifiers, so that we can work with identifiers in definitions and proofs abstractly, without unwrapping them to expose the underlying numbers. Since all we need to know about identifiers is whether they are the same or different, just a few basic facts are all we need.

```
Theorem beq_id_refl : \forall X,

true = beq_id X X.

Proof.

intros. destruct X.

apply beq_nat_refl. Qed.
```

Exercise: 1 star, optional (beq_id_eq) For this and the following exercises, do not use induction, but rather apply similar results already proved for natural numbers. Some of the tactics mentioned above may prove useful. Theorem beq_id_eq: $\forall i1 \ i2$,

```
true = beq_id i1 i2 \rightarrow i1 = i2.
Proof.
Admitted.
```

Exercise: 1 star, optional (beq_id_false_not_eq) Theorem beq_id_false_not_eq: $\forall i1$ i2,

```
\begin{array}{c} \mathsf{beq\_id} \ i1 \ i2 = \mathsf{false} \to i1 \neq i2. \\ \mathsf{Proof.} \\ Admitted. \\ \square \end{array}
```

Exercise: 1 star, optional (not_eq_beq_id_false) Theorem not_eq_beq_id_false : $\forall i1$ i2,

```
i1 \neq i2 \rightarrow \mathsf{beq\_id}\ i1\ i2 = \mathsf{false}. Proof. Admitted.
```

```
Exercise: 1 star, optional (beq_id_sym) Theorem beq_id_sym: ∀ i1 i2,
  beq_id i1 i2 = beq_id i2 i1.
Proof.
  Admitted.
```

 \Box End ID.

10.5.2 States

A *state* represents the current values of all the variables at some point in the execution of a program. For simplicity (to avoid dealing with partial functions), we let the state be defined for *all* variables, even though any given program is only going to mention a finite number of them.

```
Definition state := id \rightarrow nat.
Definition empty_state : state :=
  fun  \Rightarrow 0. 
Definition update (st : state) (X : id) (n : nat) : state :=
  fun X' \Rightarrow \text{if beq\_id } X X' \text{ then } n \text{ else } st X'.
   For proofs involving states, we'll need several simple properties of update.
Exercise: 1 star (update_eq) Theorem update_eq: \forall n \ X \ st,
  (update st \ X \ n) X = n.
Proof.
   Admitted.
Exercise: 1 star (update_neq) Theorem update_neq: \forall V2\ V1\ n\ st,
  beq_id V2\ V1 = false \rightarrow
  (update st V2 n) V1 = (st V1).
Proof.
   Admitted.
Exercise: 1 star (update_example) Before starting to play with tactics, make sure you
understand exactly what the theorem is saying!
Theorem update_example : \forall (n:nat),
  (update empty_state (ld 2) n) (ld 3) = 0.
Proof.
   Admitted.
   Exercise: 1 star, recommended (update_shadow) Theorem update_shadow : \forall x1 \ x2
k1 \ k2 \ (f : state),
```

(update (update $f \ k2 \ x1$) $k2 \ x2$) k1 = (update $f \ k2 \ x2$) k1.

```
Proof. Admitted. \Box

Exercise: 2 stars (update_same) Theorem update_same : \forall \ x1 \ k1 \ k2 \ (f : state), f \ k1 = x1 \rightarrow (update f \ k1 \ x1) \ k2 = f \ k2.

Proof. Admitted. \Box

Exercise: 3 stars (update_permute) Theorem update_permute : \forall \ x1 \ x2 \ k1 \ k2 \ k3 \ f, beq_id k2 \ k1 = false \rightarrow (update \ (update \ f \ k2 \ x1) \ k1 \ x2) \ k3 = (update \ (update \ f \ k1 \ x2) \ k2 \ x1) \ k3.

Proof. Admitted. \Box
```

10.5.3 Syntax

We can add variables to the arithmetic expressions we had before by simply adding one more constructor:

```
Inductive aexp : Type :=  | \  \, \text{ANum} : \  \, \text{nat} \to \text{aexp} \\ | \  \, \text{Ald} : \  \, \text{id} \to \text{aexp} \\ | \  \, \text{APlus} : \  \, \text{aexp} \to \text{aexp} \to \text{aexp} \\ | \  \, \text{AMinus} : \  \, \text{aexp} \to \text{aexp} \to \text{aexp} \\ | \  \, \text{AMult} : \  \, \text{aexp} \to \text{aexp} \to \text{aexp}. \\ | \  \, \text{Catic Notation "aexp\_cases"} \  \, tactic(\text{first}) \  \, ident(c) := \\ | \  \, \text{first}; \\ | \  \, Case\_aux \  \, c \ \text{"ANum"} \  \, | \  \, Case\_aux \  \, c \ \text{"AId"} \  \, | \  \, Case\_aux \  \, c \ \text{"APlus"} \\ | \  \, Case\_aux \  \, c \ \text{"AMinus"} \  \, | \  \, Case\_aux \  \, c \ \text{"AMult"} \  \, |.
```

Defining a few variable names as notational shorthands will make examples easier to read:

```
Definition X : id := Id \ 0.
Definition Y : id := Id \ 1.
Definition Z : id := Id \ 2.
```

(This convention for naming program variables (X, Y, Z) clashes a bit with our earlier use of uppercase letters for types. Since we're not using polymorphism heavily in this part of the course, this overloading should not cause confusion.)

The definition of bexps is the same as before (using the new aexps):

```
Inductive bexp: Type :=  | \ \mathsf{BTrue} : \mathbf{bexp} | \ \mathsf{BFalse} : \mathbf{bexp} | \ \mathsf{BFalse} : \mathbf{bexp} | \ \mathsf{BEq} : \mathbf{aexp} \to \mathbf{aexp} \to \mathbf{bexp} | \ \mathsf{BLe} : \mathbf{aexp} \to \mathbf{aexp} \to \mathbf{bexp} | \ \mathsf{BNot} : \mathbf{bexp} \to \mathbf{bexp} | \ \mathsf{BNot} : \mathbf{bexp} \to \mathbf{bexp} | \ \mathsf{BAnd} : \mathbf{bexp} \to \mathbf{bexp} \to \mathbf{bexp}.  Tactic Notation "bexp_cases" tactic(\mathtt{first}) \ ident(c) := \mathtt{first}; | \ \mathit{Case\_aux} \ c \ "\mathsf{BTrue}" \mid \mathit{Case\_aux} \ c \ "\mathsf{BFalse}" \mid \mathit{Case\_aux} \ c \ "\mathsf{BEq}" | \ \mathit{Case\_aux} \ c \ "\mathsf{BAnd}" \ ].
```

10.5.4 Evaluation

The arith and boolean evaluators can be extended to handle variables in the obvious way:

```
Fixpoint aeval (st : state) (e : aexp) : nat :=
  match e with
   ANum n \Rightarrow n
    Ald X \Rightarrow st X
   APlus a1 \ a2 \Rightarrow (aeval st \ a1) + (aeval st \ a2)
   AMinus a1 \ a2 \Rightarrow (aeval st \ a1) - (aeval st \ a2)
   AMult a1 \ a2 \Rightarrow (aeval st \ a1) \times (aeval st \ a2)
  end.
Fixpoint beval (st : state) (e : bexp) : bool :=
  match e with
    BTrue \Rightarrow true
    BFalse \Rightarrow false
    BEq a1 \ a2 \Rightarrow beq_nat (aeval st a1) (aeval st a2)
    BLe a1 a2 \Rightarrow ble_nat (aeval st a1) (aeval st a2)
    BNot b1 \Rightarrow \text{negb} (beval st b1)
   BAnd b1 b2 \Rightarrow andb (beval st b1) (beval st b2)
  end.
Example aexp1:
  aeval (update empty_state X 5)
          (APlus (ANum 3) (AMult (Ald X) (ANum 2)))
  = 13.
Proof. reflexivity. Qed.
Example bexp1:
  beval (update empty_state X 5)
          (BAnd BTrue (BNot (BLe (Ald X) (ANum 4))))
  = true.
```

10.6 Commands

Now we are ready define the syntax and behavior of Imp *commands* (or *statements*).

10.6.1 Syntax

Informally, commands are described by the following BNF grammar: com ::= 'SKIP' | X '::=' aexp | com ';' com | 'WHILE' bexp 'DO' com 'END' | 'IFB' bexp 'THEN' com 'ELSE' com 'FI' For example, here's the factorial function in Imp. Z ::= X; Y ::= 1; WHILE not (Z = 0) DO Y ::= Y * Z; Z ::= Z - 1 END When this command terminates, the variable <math>Y will contain the factorial of the initial value of X.

Here is the formal definition of the syntax of commands:

```
Inductive com : Type :=  | \ \mathsf{CSkip} : \mathbf{com} | \ \mathsf{CAss} : \mathbf{id} \to \mathbf{aexp} \to \mathbf{com} | \ \mathsf{CSeq} : \mathbf{com} \to \mathbf{com} \to \mathbf{com} \to \mathbf{com} | \ \mathsf{CIf} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com} \to \mathbf{com} | \ \mathsf{CWhile} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com} \to \mathbf{com} | \ \mathsf{CWhile} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com}.  Tactic Notation "com_cases" tactic(\texttt{first}) \ ident(c) := \ \mathsf{first}; | \ \mathit{Case\_aux} \ c \ "SKIP" \mid \mathit{Case\_aux} \ c \ "::=" \mid \mathit{Case\_aux} \ c \ ";" | \ \mathit{Case\_aux} \ c \ "IFB" \mid \mathit{Case\_aux} \ c \ "WHILE" | .
```

As usual, we can use a few Notation declarations to make things more readable. We need to be a bit careful to avoid conflicts with Coq's built-in notations, so we'll keep this light – in particular, we won't introduce any notations for aexps and bexps to avoid confusion with the numerical and boolean operators we've already defined. We use the keyword IFB for conditionals instead of IF, for similar reasons.

```
Notation "'SKIP'" := CSkip.

Notation "X '::=' a" := (CAss X a) (at level 60).

Notation "c1 ; c2" := (CSeq c1 c2) (at level 80, right associativity).

Notation "'WHILE' b 'DO' c 'END'" := (CWhile b c) (at level 80, right associativity).

Notation "'IFB' e1 'THEN' e2 'ELSE' e3 'FI'" := (Clf e1 e2 e3) (at level 80, right associativity).
```

For example, here is the factorial function again, written as a formal definition to Coq:

```
Definition fact_in_coq : com :=
  Z ::= Ald X;
  Y ::= ANum 1;
  WHILE BNot (BEq (Ald Z) (ANum 0)) DO
    Y ::= AMult (Ald Y) (Ald Z);
    Z ::= AMinus (Ald Z) (ANum 1)
  END.
          Examples
10.6.2
Assignment:
Definition plus2 : com :=
  X ::= (APlus (Ald X) (ANum 2)).
Definition XtimesYinZ : com :=
  Z ::= (AMult (Ald X) (Ald Y)).
Definition subtract_slowly_body : com :=
  Z ::= AMinus (Ald Z) (ANum 1);
  X ::= AMinus (Ald X) (ANum 1).
   Loops:
Definition subtract_slowly : com :=
  WHILE BNot (BEq (Ald X) (ANum 0)) DO
    subtract_slowly_body
  END.
Definition subtract_3_from_5_slowly : com :=
  X ::= ANum 3;
  Z ::= ANum 5;
  subtract_slowly.
   An infinite loop:
Definition loop: com :=
  WHILE BTrue DO
    SKIP
  END.
   Factorial again (broken up into smaller pieces this time, for convenience when we come
back to proving things about it later).
Definition fact_body : com :=
  Y ::= AMult (Ald Y) (Ald Z) ;
  Z ::= AMinus (Ald Z) (ANum 1).
```

Definition fact_loop : com :=

WHILE BNot (BEq (Ald Z) (ANum 0)) DO

```
fact_body
END.

Definition fact_com : com :=
Z ::= Ald X ;
Y ::= ANum 1 ;
fact_loop.
```

10.7 Evaluation

Next we need to define what it means to evaluate an Imp command. The fact that WHILE loops don't necessarily terminate makes defining an evaluation function tricky ...

10.7.1 Evaluation Function (Failed Attempt)

Here's an attempt at defining an evaluation function for commands, omitting the WHILE case.

```
Fixpoint ceval_fun_no_while (st : state) (c : com) : state :=
  match c with
     \mid SKIP \Rightarrow
          st
     | l ::= a1 \Rightarrow
          update st l (aeval st a1)
     | c1 ; c2 \Rightarrow
          let st' := ceval\_fun\_no\_while st c1 in
          ceval_fun_no_while st' c2
     | IFB b THEN c1 ELSE c2 FI \Rightarrow
          if (beval st \ b)
             then ceval_fun_no_while st c1
             else ceval_fun_no_while st\ c2
     | WHILE b1 DO c1 END \Rightarrow
          st
  end.
```

In a traditional functional programming language like ML or Haskell we could write the WHILE case as follows:

```
Fixpoint ceval_fun (st : state) (c : com) : state :=
  match c with
    ...
  | WHILE b1 D0 c1 END =>
      if (beval st b1)
        then ceval_fun st (c1; WHILE b1 D0 c1 END)
      else st
```

end.

Coq doesn't accept such a definition (*Error*: Cannot guess decreasing argument of fix) because the function we want to define is not guaranteed to terminate. Indeed, the full version of the ceval_fun function applied to the loop program above would never terminate. Since Coq is not just a functional programming language, but also a consistent logic, any potentially non-terminating function needs to be rejected. Here is an invalid(!) Coq program showing what would go wrong if Coq allowed non-terminating recursive functions:

```
Fixpoint loop_false (n : nat) : False := loop_false n.
```

That is, propositions like False would become provable (e.g. $loop_false$ 0 would be a proof of False), which would be a disaster for Coq's logical consistency.

Thus, because it doesn't terminate on all inputs, the full version of $ceval_fun$ cannot be written in Coq – at least not without additional tricks, which make everything much more complicated (see chapter ImpCEvalFun if curious).

10.7.2 Evaluation as a Relation

Here's a better way: we define ceval as a relation rather than a function – i.e., we define it in Prop instead of Type, as we did for aevalR and bevalR above.

This is an important change. Besides freeing us from the hacks that would be needed to define an evaluation function, it gives us a lot more flexibility in the definition. For example, if we added concurrency features to the language, we'd want the definition of evaluation to be non-deterministic – i.e., not only would it not be total, it would not even be a partial function!

We'll use the notation $c / st \mid\mid st'$ for our *ceval* relation, that is $c / st \mid\mid st'$ means that executing program c in a starting state st results in an ending state st'. This can be pronounced "c takes state st to st".

```
(E_Skip) SKIP / st || st
aeval st a1 = n

(E_Ass) X := a1 / st || (update st X n)
c1 / st || st' c2 / st' || st"

(E_Seq) c1;c2 / st || st"
beval st b1 = true c1 / st || st'

(E_IfTrue) IF b1 THEN c1 ELSE c2 FI / st || st'
beval st b1 = false c2 / st || st'
```

```
(E_IfFalse) IF b1 THEN c1 ELSE c2 FI / st || st' beval st b1 = false
```

```
(E_WhileEnd) WHILE b1 DO c1 END / st || st
    beval st b1 = true c1 / st \parallel st' WHILE b1 DO c1 END / st' \parallel st"
(E_WhileLoop) WHILE b1 DO c1 END / st || st"
    Here is the formal definition. (Make sure you understand how it corresponds to the
inference rules.)
Reserved Notation "c1',' st'||' st'" (at level 40, st at level 39).
Inductive ceval: com \rightarrow state \rightarrow state \rightarrow Prop :=
   \mid \mathsf{E}_{\mathsf{-}}\mathsf{Skip} : \forall st,
        SKIP / st \mid \mid st
   \mid \mathsf{E}_{-}\mathsf{Ass} : \forall st \ a1 \ n \ X,
        aeval st a1 = n \rightarrow
         (X ::= a1) / st \mid\mid (update st X n)
   \mid \mathsf{E\_Seq} : \forall \ c1 \ c2 \ st \ st' \ st'',
        c1 / st \mid \mid st' \rightarrow
        c2 / st' \mid \mid st'' \rightarrow
         (c1; c2) / st || st"
   \mid \mathsf{E\_IfTrue} : \forall st st' b1 c1 c2,
        beval st b1 = true \rightarrow
        c1 / st \mid \mid st' \rightarrow
         (IFB b1 THEN c1 ELSE c2 FI) / st || st
   \mid \mathsf{E_IfFalse} : \forall st st' b1 c1 c2,
        beval st b1 = false \rightarrow
        c2 / st \mid \mid st' \rightarrow
         (IFB b1 THEN c1 ELSE c2 FI) / st | | st
   \mid \mathsf{E}_{-}\mathsf{WhileEnd} : \forall b1 \ st \ c1,
        beval st b1 = false \rightarrow
         (WHILE b1 DO c1 END) / st || st
   \mid \mathsf{E}_{-}\mathsf{WhileLoop} : \forall st \ st' \ st'' \ b1 \ c1,
        beval st b1 = true \rightarrow
         c1 / st \mid \mid st' \rightarrow
         (WHILE b1 DO c1 END) / st' || st'' \rightarrow
         (WHILE b1 DO c1 END) / st \mid \mid st"
   where "c1 '/' st '||' st'" := (ceval c1 \ st \ st').
Tactic Notation "ceval_cases" tactic(first) ident(c) :=
   first;
   [ Case_aux c "E_Skip" | Case_aux c "E_Ass" | Case_aux c "E_Seq"
    Case_aux c "E_IfTrue" | Case_aux c "E_IfFalse"
   | Case_aux c "E_WhileEnd" | Case_aux c "E_WhileLoop" ].
```

The cost of defining evaluation as a relation instead of a function is that we now need to construct *proofs* that some program evaluates to some result state, rather than just letting Coq's computation mechanism do it for us.

```
Example ceval_example1:
    (X ::= ANum 2;
     IFB BLe (Ald X) (ANum 1)
       THEN Y ::= ANum 3
       ELSE Z ::= ANum 4
     FI)
   / empty_state
   | | (update (update empty_state X 2) Z 4).
Proof.
  apply E_Seq with (update empty_state X 2).
  Case "assignment command".
    apply E_Ass. reflexivity.
  Case "if command".
    apply E_IfFalse.
      reflexivity.
      apply E_Ass. reflexivity. Qed.
Exercise: 2 stars (ceval_example2) Example ceval_example2:
    (X ::= ANum 0; Y ::= ANum 1; Z ::= ANum 2) / empty_state | |
    (update (update (update empty_state X 0) Y 1) Z 2).
Proof.
   Admitted.
   Exercise: 3 stars, optional (pup_to_n) Write an Imp program that sums the numbers
from 1 to X (inclusive: 1+2+...+X) in the variable Y. Prove that this program executes
as intended for X = 2 (this latter part is trickier than you might expect).
Definition pup_to_n : com :=
  admit.
Theorem pup_to_2_ceval:
  pup_to_n / (update empty_state X 2) ||
    update (update (update (update (update empty_state
      X 2) Y 0) Y 2) X 1) Y 3) X 0.
Proof.
   Admitted.
```

10.7.3 Determinism of Evaluation

Changing from a computational to a relational definition of evaluation is a good move because it allows us to escape from the artificial requirement (imposed by Coq's restrictions on Fixpoint definitions) that evaluation should be a total function. But it also raises a question: Is the second definition of evaluation actually a partial function? That is, is it possible that, beginning from the same state st, we could evaluate some command c in different ways to reach two different output states st and st?

In fact, this cannot happen: *ceval* is a partial function. Here's the proof:

```
Theorem ceval_deterministic: \forall c \ st \ st1 \ st2,
     c / st \mid \mid st1 \rightarrow
     c / st \mid \mid st2 \rightarrow
     st1 = st2.
Proof.
  intros c st st1 st2 E1 E2.
  generalize dependent st2.
  ceval_cases (induction E1) Case;
            intros st2 E2; inversion E2; subst.
  Case "E_Skip". reflexivity.
  Case "E_Ass". reflexivity.
  Case "E_Seq".
    assert (st' = st'\theta) as EQ1.
       SCase "Proof of assertion". apply IHE1_1; assumption.
    subst st'0.
    apply IHE1_{-}2. assumption.
  Case "E_IfTrue".
    SCase "b1 evaluates to true".
       apply IHE1. assumption.
    SCase "b1 evaluates to false (contradiction)".
      rewrite H in H5. inversion H5.
  Case "E_IfFalse".
    SCase "b1 evaluates to true (contradiction)".
      rewrite H in H5. inversion H5.
    SCase "b1 evaluates to false".
      apply IHE1. assumption.
  Case "E_WhileEnd".
    SCase "b1 evaluates to true".
      reflexivity.
    SCase "b1 evaluates to false (contradiction)".
      rewrite H in H2. inversion H2.
  Case "E_WhileLoop".
    SCase "b1 evaluates to true (contradiction)".
      rewrite H in H4. inversion H4.
```

```
SCase "b1 evaluates to false".

assert (st' = st'0) as EQ1.

SSCase "Proof of assertion". apply IHE1_1; assumption. subst st'0.

apply IHE1_2. assumption. Qed.
```

10.8 Reasoning About Programs

We'll get much deeper into systematic techniques for reasoning about Imp programs in the following chapters, but we can do quite a bit just working with the bare definitions. This section explores some examples.

10.8.1 Basic Examples

```
Theorem plus2_spec : \forall st \ n \ st',
  st X = n \rightarrow
  plus2 / st \mid \mid st' \rightarrow
  st' X = n + 2.
Proof.
  intros st n st' HX Heval.
  inversion Heval. subst. clear Heval. simpl.
  apply update_eq. Qed.
Exercise: 3 stars, recommended (XtimesYinZ_spec) State and prove a specification
of XtimesYinZ.
   Exercise: 3 stars, recommended (loop_never_stops) Theorem loop_never_stops: \forall
st st',
  \sim (loop / st \mid \mid st').
Proof.
  intros st st' contra. unfold loop in contra.
  remember (WHILE BTrue DO SKIP END) as loopdef.
   Admitted.
   Fixpoint no_whiles (c : \mathbf{com}) : \mathbf{bool} :=
  match c with
   SKIP \Rightarrow true
   _ ::= _ ⇒ true
   c1; c2 \Rightarrow andb (no_whiles c1) (no_whiles c2)
   IFB _ THEN ct ELSE cf FI \Rightarrow andb (no_whiles ct) (no_whiles cf)
```

```
| WHILE _{-} DO _{-} END \Rightarrow false end.
```

Exercise: 3 stars, optional (no_whilesR) The no_whiles property yields true on just those programs that have no while loops. Using Inductive, write a property $no_whilesR$ such that $no_whilesR$ c is provable exactly when c is a program with no while loops. Then prove its equivalence with no_whiles .

```
Inductive no\_whilesR: com \rightarrow Prop :=
. Theorem no\_whiles\_eqv:
\forall \ c, \ no\_whiles \ c = true \leftrightarrow no\_whilesR \ c.
Proof.
```

Admitted.

Exercise: 4 stars, optional (no_whiles_terminating) Imp programs that don't involve while loops always terminate. State and prove a theorem that says this. (Use either no_whiles or no_whilesR, as you prefer.)

10.8.2 Proving a Program Correct (Optional)

Recall the factorial program:

Print fact_body. Print fact_loop. Print fact_com.

Here is an alternative "mathematical" definition of the factorial function:

```
Fixpoint real_fact (n:\mathsf{nat}): \mathsf{nat} := \mathsf{match}\ n \ \mathsf{with} \ | \ \mathsf{O} \Rightarrow 1 \ | \ \mathsf{S}\ n' \Rightarrow n \times (\mathsf{real\_fact}\ n') \ \mathsf{end}.
```

We would like to show that they agree – if we start $fact_com$ in a state where variable X contains some number x, then it will terminate in a state where variable Y contains the factorial of x.

To show this, we rely on the critical idea of a *loop invariant*.

```
Definition fact_invariant (x:\mathbf{nat}) (st:\mathsf{state}) := (st \ \mathsf{Y}) \times (\mathsf{real\_fact}\ (st \ \mathsf{Z})) = \mathsf{real\_fact}\ x.
Theorem fact_body_preserves_invariant: \forall\ st\ st'\ x, fact_invariant x\ st\ \to st\ \mathsf{Z} \neq 0 \to
```

```
fact\_body / st | | st' \rightarrow
     fact_invariant x st'.
Proof.

  Case "st" Z = 0". simpl in H0. omega.
  Case "st" Z > 0 (impossible)". inversion H5.
Qed.
```

One might wonder whether all this work with poking at states and unfolding definitions could be ameliorated with some more powerful lemmas and/or more uniform reasoning principles... Indeed, this is exactly the topic of the upcoming *Hoare* chapter!

Exercise: 4 stars, optional (subtract_slowly_spec) Prove a specification for subtract_slowly, using the above specification of fact_com and the invariant below as guides.

```
Definition ss_invariant (x:nat) (z:nat) (st:state) := minus (st \ Z) (st \ X) = minus z \ x.
```

10.9 Additional Exercises

Exercise: 4 stars, optional (add_for_loop) Add C-style for loops to the language of commands, update the *ceval* definition to define the semantics of for loops, and add cases for for loops as needed so that all the proofs in this file are accepted by Coq.

A for loop should be parameterized by (a) a statement executed initially, (b) a test that is run on each iteration of the loop to determine whether the loop should continue, (c) a statement executed at the end of each loop iteration, and (d) a statement that makes up the body of the loop. (You don't need to worry about making up a concrete Notation for for loops, but feel free to play with this too if you like.)

Exercise: 3 stars, optional (short_circuit) Most modern programming languages use a "short-circuit" evaluation rule for boolean and: to evaluate BAnd b1 b2, first evaluate b1. If it evaluates to false, then the entire BAnd expression evaluates to false immediately, without evaluating b2. Otherwise, b2 is evaluated to determine the result of the BAnd expression.

Write an alternate version of beval that performs short-circuit evaluation of BAnd in this manner, and prove that it is equivalent to beval.

Exercise: 4 stars, recommended (stack_compiler) HP Calculators, programming languages like Forth and Postscript, and abstract machines like the Java Virtual Machine all evaluate arithmetic expressions using a stack. For instance, the expression

```
(2*3)+(3*(4-2))
```

would be entered as

and evaluated like this:

The task of this exercise is to write a small compiler that translates *aexps* into stack machine instructions, and to prove its correctness.

The instruction set for our stack language will consist of the following instructions:

- SPush n: Push the number n on the stack.
- SLoad X: Load the identifier X from the store and push it on the stack

- *SPlus*: Pop the two top numbers from the stack, add them, and push the result onto the stack.
- SMinus: Similar, but subtract.
- *SMult*: Similar, but multiply.

```
Inductive sinstr : Type :=
| SPush : nat → sinstr
| SLoad : id → sinstr
| SPlus : sinstr
| SMinus : sinstr
| SMult : sinstr.
```

Write a function to evaluate programs in the stack language. It takes as input a state, a stack represented as a list of numbers (top stack item is the head of the list), and a program represented as a list of instructions, and returns the stack after executing the program. Test your function on the examples below.

Note that the specification leaves unspecified what to do when encountering an *SPlus*, *SMinus*, or *SMult* instruction if the stack contains less than two elements. In a sense it is immaterial, since our compiler will never emit such a malformed program. However, when you do the correctness proof you may find some choices makes the proof easier than others.

Next, write a function which compiles an *aexp* into a stack machine program. The effect of running the program should be the same as pushing the value of the expression on the stack.

```
Fixpoint s_compile (e : aexp) : list sinstr := admit.
```

Finally, prove the following theorem, stating that the *compile* function behaves correctly. You will need to start by stating a more general lemma to get a usable induction hypothesis.

```
Theorem s_compile_correct : \forall (st : state) (e : aexp), s_execute st [] (s_compile e) = [ aeval st e ]. Proof.

Admitted.
```

Chapter 11

Library ImpParser

11.1 ImpParser: Lexing and Parsing in Coq

The development of the *Imp* language in Imp.v completely ignores issues of concrete syntax – how an ascii string that a programmer might write gets translated into the abstract syntax trees defined by the datatypes *aexp*, *bexp*, and *com*. In this file we illustrate how the rest of the story can be filled in by building a simple lexical analyzer and parser using Coq's functional programming facilities.

This development is not intended to be understood in detail: the explanations are fairly terse and there are no exercises. The main point is simply to demonstrate that it can be done. You are invited to look through the code – most of it is not very complicated, though the parser relies on some "monadic" programming idioms that may require a little work to make out – but most readers will probably want to just skip down to the Examples section at the very end to get the punchline.

11.2 Internals

```
Require Import SfLib.
Require Import Imp.
Require Import String.
Require Import Ascii.
Open Scope list_scope.
```

11.2.1 Lexical Analysis

```
Definition isWhite (c: ascii): bool :=
  let n := nat_of_ascii c in
  orb (orb (beq_nat n 32)
```

```
(\mathsf{beq\_nat}\ n\ 9))
        (orb (beq_nat n 10)
              (beq_nat n 13)).
Notation "x '\leq=?' y" := (ble_nat x y)
  (at level 70, no associativity) : nat\_scope.

```

11.3 Examples

Chapter 12

Library ImpCEvalFun

12.1 ImpCEvalFun: Evaluation Function for Imp

12.1.1 Evaluation Function

```
Require Import Imp.
```

Here's a first try at an evaluation function for commands, omitting WHILE.

```
Fixpoint ceval_step1 (st : state) (c : com) : state :=
  match c with
     | SKIP \Rightarrow
          st
     | l ::= a1 \Rightarrow
          update st l (aeval st a1)
     | c1 ; c2 \Rightarrow
          let st' := ceval\_step1 \ st \ c1 in
          ceval_step1 st ' c2
     | IFB b THEN c1 ELSE c2 FI \Rightarrow
          if (beval st b)
             then ceval_step1 st c1
             else ceval_step1 st c2
     | WHILE b1 DO c1 END \Rightarrow
          st
  end.
```

In a traditional functional programming language like ML or Haskell we could write the WHILE case as follows:

```
| WHILE b1 D0 c1 END =>
   if (beval st b1)
     then ceval_step1 st (c1; WHILE b1 D0 c1 END)
   else st
```

Coq doesn't accept such a definition (Error: Cannot guess decreasing argument of fix) because the function we want to define is not guaranteed to terminate. Indeed, the changed ceval_step1 function applied to the loop program from Imp.v would never terminate. Since Coq is not just a functional programming language, but also a consistent logic, any potentially non-terminating function needs to be rejected. Here is an invalid(!) Coq program showing what would go wrong if Coq allowed non-terminating recursive functions:

```
Fixpoint loop_false (n : nat) : False := loop_false n.
```

That is, propositions like False would become provable (e.g. $loop_false$ 0 would be a proof of False), which would be a disaster for Coq's logical consistency.

Thus, because it doesn't terminate on all inputs, the full version of *ceval_step1* cannot be written in Coq – at least not without one additional trick...

Second try, using an extra numeric argument as a "step index" to ensure that evaluation always terminates.

```
Fixpoint ceval_step2 (st : state) (c : com) (i : nat) : state :=
  match i with
    0 \Rightarrow \text{empty\_state}
   \mid S i' \Rightarrow
     match c with
        \mid SKIP \Rightarrow
              st
        | l ::= a1 \Rightarrow
              update st\ l\ (aeval\ st\ a1)
        | c1 ; c2 \Rightarrow
              let st' := \text{ceval\_step2} \ st \ c1 \ i' in
              ceval_step2 st' c2 i'
        | IFB b THEN c1 ELSE c2 FI \Rightarrow
              if (beval st b)
                 then ceval_step2 st c1 i'
                 else ceval_step2 st c2 i'
        | WHILE b1 DO c1 END \Rightarrow
              if (beval st b1)
              then let st' := \text{ceval\_step2} \ st \ c1 \ i' in
                     ceval_step2 st ' c i '
              else st
     end
  end.
```

Note: It is tempting to think that the index i here is counting the "number of steps of evaluation." But if you look closely you'll see that this is not the case: for example, in the rule for sequencing, the same i is passed to both recursive calls. Understanding the exact way that i is treated will be important in the proof of $ceval_ceval_step$, which is given as an exercise below.

Third try, returning an *option state* instead of just a *state* so that we can distinguish between normal and abnormal termination.

```
Fixpoint ceval_step3 (st : state) (c : com) (i : nat)
                            : option state :=
  match i with
    O \Rightarrow None
  \mid S i' \Rightarrow
     match c with
        | SKIP \Rightarrow
              Some st
        | l ::= a1 \Rightarrow
              Some (update st\ l\ (aeval\ st\ a1))
        |c1;c2\Rightarrow
              match (ceval_step3 st c1 i') with
              | Some st' \Rightarrow \text{ceval\_step3} st' c2 i'
              | None \Rightarrow None
              end
        | IFB b THEN c1 ELSE c2 FI \Rightarrow
              if (beval st \ b)
                then ceval_step3 st c1 i'
                 else ceval_step3 st c2 i
        | WHILE b1 DO c1 END \Rightarrow
              if (beval st b1)
              then match (ceval_step3 st c1 i') with
                     | Some st' \Rightarrow \text{ceval\_step3 } st' \ c \ i'
                     | None \Rightarrow None |
                     end
              else Some st
     end
  end.
```

We can improve the readability of this definition by introducing a bit of auxiliary notation to hide the "plumbing" involved in repeatedly matching against optional states.

```
Notation "'LETOPT' \mathbf{x} <== \mathrm{e}1 'IN' \mathrm{e}2" := (\mathrm{match}\ e1\ \mathrm{with} \\ |\ \mathsf{Some}\ x \Rightarrow e2\ \\ |\ \mathsf{None} \Rightarrow \mathsf{None} \\ \mathrm{end}) \\ (\mathrm{right}\ \mathsf{associativity},\ \mathsf{at}\ \mathsf{level}\ 60). Fixpoint \mathsf{ceval\_step}\ (st:\mathsf{state})\ (c:\mathsf{com})\ (i:\mathsf{nat}) \\ :\ \mathsf{option}\ \mathsf{state} := \\ \mathsf{match}\ i\ \mathsf{with}
```

```
\mid \mathsf{O} \Rightarrow \mathsf{None}
  |Si' \Rightarrow
     {\tt match}\ c\ {\tt with}
        | SKIP \Rightarrow
              Some st
        | l ::= a1 \Rightarrow
              Some (update st\ l (aeval st\ a1))
        | c1 ; c2 \Rightarrow
              LETOPT st' \le cval\_step st c1 i' IN
              ceval_step st' c2 i'
        | IFB b THEN c1 ELSE c2 FI \Rightarrow
              if (beval st \ b)
                then ceval_step st \ c1 \ i'
                 else ceval_step st c2 i'
        | WHILE b1 DO c1 END \Rightarrow
              if (beval st b1)
              then LETOPT st' \le cval\_step st c1 i' IN
                     ceval\_step st' c i'
              else Some st
     end
  end.
Definition test_ceval (st:state) (c:com) :=
  match ceval_step st\ c\ 500 with
  | None \Rightarrow None
  Some st \Rightarrow Some (st X, st Y, st Z)
  end.
```

Exercise: 2 stars, recommended (pup_to_n) Write an Imp program that sums the numbers from 1 to X (inclusive: 1 + 2 + ... + X) in the variable Y. Make sure your solution satisfies the test that follows.

```
Definition pup_to_n : com :=
   admit.
```

Exercise: 2 stars, optional (peven) Write a While program that sets Z to 0 if X is even and sets Z to 1 otherwise. Use $ceval_test$ to test your program.

12.1.2 Equivalence of Relational and Step-Indexed Evaluation

As with arithmetic and boolean expressions, we'd hope that the two alternative definitions of evaluation actually boil down to the same thing. This section shows that this is the case. Make sure you understand the statements of the theorems and can follow the structure of the proofs.

```
Theorem ceval_step__ceval: \forall c \ st \ st',
      (\exists i, \text{ ceval\_step } st \ c \ i = \text{Some } st') \rightarrow
      c / st || st'.
Proof.
  intros c st st' H.
  inversion H as [i E].
  clear H.
  generalize dependent st'.
  generalize dependent st.
  generalize dependent c.
  induction i as [|i'|].
  Case "i = 0 - contradictory".
    intros c st st H. inversion H.
  Case "i = S i".
    intros c st st' H.
    com_cases (destruct c) SCase;
            simpl in H; inversion H; subst; clear H.
       SCase "SKIP". apply E_Skip.
       SCase "::=". apply E_Ass. reflexivity.
       SCase ":".
         remember (ceval_step st \ c1 \ i') as r1. destruct r1.
         SSCase "Evaluation of r1 terminates normally".
           apply E_Seq with s.
             apply IHi'. rewrite Heqr1. reflexivity.
              apply IHi'. simpl in H1. assumption.
         SSCase "Otherwise – contradiction".
           inversion H1.
       SCase "IFB".
         remember (beval st b) as r. destruct r.
         SSCase "r = true".
           apply E_lfTrue. rewrite Hegr. reflexivity.
           apply IHi'. assumption.
         SSCase "r = false".
           apply E_lfFalse. rewrite Hegr. reflexivity.
           apply IHi'. assumption.
```

```
SCase "WHILE". remember (beval st b) as r. destruct r. SSCase "r = true". remember (ceval_step st c i') as r1. destruct r1. SSSCase "r1 = Some s". apply E_WhileLoop with s. rewrite Heqr. reflexivity. apply IHi'. rewrite Heqr1. reflexivity. apply IHi'. simpl in H1. assumption. SSSCase "r1 = None". inversion H1. SSCase "r = false". inversion H1. apply E_WhileEnd. rewrite Heqr. subst. reflexivity. Qed.
```

Exercise: 4 stars (ceval_step__ceval_inf) Write an informal proof of ceval_step__ceval, following the usual template. (The template for case analysis on an inductively defined value should look the same as for induction, except that there is no induction hypothesis.) Make your proof communicate the main ideas to a human reader; do not simply transcribe the steps of the formal proof.

```
Theorem ceval_step_more: \forall i1 \ i2 \ st \ st' \ c,
  i1 \leq i2 \rightarrow
  ceval_step st \ c \ i1 = Some \ st' \rightarrow
  ceval_step st c i2 = Some st'.
Proof.
induction i1 as [i1']; intros i2 st st' c Hle Hceval.
  Case "i1 = 0".
    simpl in Hceval. inversion Hceval.
  Case "i1 = S i1'".
    destruct i2 as [|i2'|]. inversion Hle.
    assert (Hle': i1' \leq i2') by omega.
     com\_cases (destruct c) SCase.
     SCase "SKIP".
       simpl in Hceval. inversion Hceval.
       reflexivity.
    SCase "::=".
       simpl in Hceval. inversion Hceval.
       reflexivity.
     SCase ";".
       simpl in Hceval. simpl.
       remember (ceval_step st c1 i1') as st1'o.
       destruct st1'o.
```

```
SSCase "st1'o = Some".
    symmetry in Hegst1'o.
    apply (IHi1' i2') in Heqst1'o; try assumption.
    rewrite Heqst1'o. simpl. simpl in Hceval.
    apply (IHi1' i2') in Hceval; try assumption.
  SSCase "st1'o = None".
    inversion Hceval.
SCase "IFB".
  simpl in Hceval. simpl.
  remember (beval st b) as bval.
 destruct bval; apply (IHi1' i2') in Hceval; assumption.
SCase "WHILE".
  simpl in Hceval. simpl.
 destruct (beval st b); try assumption.
  remember (ceval_step st c i1') as st1'o.
 destruct st1'o.
  SSCase "st1'o = Some".
    symmetry in Heast1'o.
    apply (IHi1' i2') in Heqst1'o; try assumption.
    rewrite \rightarrow Hegst1'o. simpl. simpl in Hceval.
    apply (IHi1' i2') in Hceval; try assumption.
  SSCase "i1'o = None".
    simpl in Hceval. inversion Hceval. Qed.
```

Exercise: 3 stars, recommended (ceval_ceval_step) Finish the following proof. You'll need $ceval_step_more$ in a few places, as well as some basic facts about \leq and plus.

```
Theorem ceval__ceval_step: \forall \ c \ st \ st', c \ / \ st \ | \ | \ st' \rightarrow \exists \ i, ceval_step st \ c \ i = \mathsf{Some} \ st'.

Proof.

intros c \ st \ st' \ Hce.

ceval\_cases (induction Hce) Case.

Admitted.

\Box

Theorem ceval_and_ceval_step_coincide: \forall \ c \ st \ st',
c \ / \ st \ | \ st'
\leftrightarrow \exists \ i, ceval_step st \ c \ i = \mathsf{Some} \ st'.

Proof.

intros c \ st \ st'.

split. apply ceval\_ceval\_step. apply ceval_step_ceval.

Qed.
```

12.1.3 Determinism of Evaluation (Simpler Proof)

Here's a slicker proof showing that the evaluation relation is deterministic, using the fact that the relational and step-indexed definition of evaluation are the same.

```
Theorem ceval_deterministic': \forall \ c \ st \ st1 \ st2, c \ / \ st \ | \ | \ st1 \rightarrow c \ / \ st \ | \ | \ st2 \rightarrow st1 = st2.

Proof.

intros c \ st \ st1 \ st2 \ He1 \ He2.
apply ceval\_ceval\_step in He1.
apply ceval\_ceval\_step in He2.
inversion He1 as [i1 \ E1].
inversion He2 as [i2 \ E2].
apply ceval\_step\_more with (i2 := i1 + i2) in E1. apply ceval\_step\_more with (i2 := i1 + i2) in E2. rewrite E1 in E2. inversion E2. reflexivity. omega. Omega. Qed.
```

Chapter 13

Library Extraction

13.1 Extraction: Extracting ML from Coq

13.2 Basic Extraction

In its simplest form, program extraction from Coq is completely straightforward.

First we say what language we want to extract into. Options are OCaml (the most mature), Haskell (which mostly works), and Scheme (a bit out of date).

Extraction Language Ocaml.

Now we load up the Coq environment with some definitions, either directly or by importing them from other modules.

Require Import SfLib.

Require Import ImpCEvalFun.

Finally, we tell Coq the name of a definition to extract and the name of a file to put the extracted code into.

Extraction "imp1.ml" ceval_step.

When Coq processes this command, it generates a file imp1.ml containing an extracted version of $ceval_step$, together with everything that it recursively depends on. Have a look at this file now.

13.3 Controlling Extraction of Specific Types

We can tell Coq to extract certain Inductive definitions to specific OCaml types. For each one, we must say

- how the Coq type itself should be represented in OCaml, and
- how each constructor should be translated.

```
Extract Inductive bool ⇒ "bool" [ "true" "false" ].
```

Also, for non-enumeration types (where the constructors take arguments), we give an OCaml expression that can be used as a "recursor" over elements of the type. (Think Church numerals.)

```
Extract Inductive nat \Rightarrow "int"
[ "0" "(fun x -> x + 1)" ]
"(fun zero succ n -> if n=0 then zero () else succ (n-1))".
```

We can also extract defined constants to specific OCaml terms or operators.

```
Extract Constant plus \Rightarrow "( + )".

Extract Constant mult \Rightarrow "( * )".

Extract Constant beq_nat \Rightarrow "( = )".
```

Important: It is entirely *your responsibility* to make sure that the translations you're proving make sense. For example, it might be tempting to include this one Extract Constant minus => "(-)". but doing so could lead to serious confusion! (Why?)

```
Extraction "imp2.ml" ceval_step.
```

Have a look at the file imp2.ml. Notice how the fundamental definitions have changed from imp1.ml.

13.4 A Complete Example

To use our extracted evaluator to run Imp programs, all we need to add is a tiny driver program that calls the evaluator and somehow prints out the result.

For simplicity, we'll print results by dumping out the first four memory locations in the final state.

Also, to make it easier to type in examples, let's extract a parser from the *ImpParser* Coq module. To do this, we need a few more declarations to set up the right correspondence between Coq strings and lists of OCaml characters.

```
Require Import Ascii String.

Extract Inductive ascii \Rightarrow char [

"(* If this appears, you're using Ascii internals. Please don't *) (fun (b0,b1,b2,b3,b4,b5,b6,b7) -> let f b i = if b then 1 lsl i else 0 in Char.chr (f b0 0 + f b1 1 + f b2 2 + f b3 3 + f b4 4 + f b5 5 + f b6 6 + f b7 7))"

["(* If this appears, you're using Ascii internals. Please don't *) (fun f c -> let n = Char.code c in let h i = (n land (1 lsl i)) <> 0 in f (h 0) (h 1) (h 2) (h 3) (h 4) (h 5) (h 6) (h 7))".

Extract Constant zero \Rightarrow "'\000'".

Extract Constant one \Rightarrow "'\001'".

Extract Constant shift \Rightarrow

"fun b c -> Char.chr (((Char.code c) lsl 1) land 255 + if b then 1 else 0)".
```

Extract Inlined Constant ascii_dec \Rightarrow "(=)".

We also need one more variant of booleans.

Extract Inductive sumbool \Rightarrow "bool" ["true" "false"].

The extraction is the same as always.

Require Import Imp.

Require Import ImpParser.

Extraction "imp.ml" empty_state ceval_step parse.

Now let's run our generated Imp evaluator. First, have a look at *impdriver.ml*. (This was written by hand, not extracted.)

Next, compile the driver together with the extracted code and execute it, as follows.

```
ocamlc -w -20 -w -26 -o impdriver imp.mli imp.ml impdriver.ml ./impdriver
```

(The -w flags to ocamle are just there to suppress a few spurious warnings.)

13.5 Discussion

Since we've proved that the *ceval_step* function behaves the same as the *ceval* relation in an appropriate sense, the extracted program can be viewed as a *certified* Imp interpreter. (Of course, the parser is not certified in any interesting sense, since we didn't prove anything about it.)

Chapter 14

Library Equiv

14.1 Equiv: Program Equivalence

Require Export Imp.

Some general advice for working on problems

- We've tried to make sure that most of the Coq proofs we ask you to do are similar to proofs that we've provided. Before starting to work on the homework problems, take the time to work through our proofs (both informally, on paper, and in Coq) and make sure you understand them in detail. This will save you a lot of time.
- The Coq proofs we're doing now are sufficiently complicated that it is more or less impossible to complete them simply by "following your nose" or random hacking. You need to start with an idea about why the property is true and how the proof is going to go. The best way to do this is to write out at least a sketch of an informal proof on paper one that intuitively convinces you of the truth of the theorem before starting to work on the formal one.
- Use automation to save work! Some of the proofs in this chapter's exercises are pretty long if you try to write out all the cases explicitly.

14.2 Behavioral Equivalence

In the last chapter, we investigated the correctness of a very simple program transformation: the *optimize_Oplus* function. The programming language we were considering was the first version of the language of arithmetic expressions – with no variables – so in that setting it was very easy to define what it *means* for a program transformation to be correct: it should always yield a program that evaluates to the same number as the original.

To go further and talk about the correctness of program transformations in the full Imp language, we need to consider the role of variables and state.

14.2.1 Definitions

For aexps and bexps with variables, the definition we want is clear. We say that two aexps or bexps are behaviorally equivalent if they evaluate to the same result in every state.

```
Definition aequiv (a1 \ a2 : \mathbf{aexp}) : \mathsf{Prop} := \forall \ (st : \mathsf{state}), aeval st \ a1 = \mathsf{aeval} \ st \ a2.
Definition bequiv (b1 \ b2 : \mathbf{bexp}) : \mathsf{Prop} := \forall \ (st : \mathsf{state}), beval st \ b1 = \mathsf{beval} \ st \ b2.
```

For commands, the situation is a little more subtle. We can't simply say "two commands are behaviorally equivalent if they evaluate to the same ending state whenever they are started in the same initial state," because some commands (in some starting states) don't terminate in any final state at all! What we need instead is this: two commands are behaviorally equivalent if, for any given starting state, they either both diverge or both terminate in the same final state. A compact way to express this is "if the first one terminates in a particular state then so does the second, and vice versa."

```
Definition cequiv (c1 \ c2 : \mathbf{com}) : \mathsf{Prop} := \forall \ (st \ st' : \mathsf{state}), \ (c1 \ / \ st \ || \ st') \leftrightarrow (c2 \ / \ st \ || \ st').
```

Exercise: 2 stars, optional (pairs_equiv) Which of the following pairs of programs are equivalent? Write "yes" or "no" for each one.

- (a) WHILE (BLe (ANum 1) (AId X)) DO X ::= APlus (AId X) (ANum 1) END and WHILE (BLe (ANum 2) (AId X)) DO X ::= APlus (AId X) (ANum 1) END
- (b) WHILE BTrue DO WHILE BFalse DO X ::= APlus (AId X) (ANum 1) END END and WHILE BFalse DO WHILE BTrue DO X ::= APlus (AId X) (ANum 1) END END \Box

Exercise: 3 stars (equiv_classes) Given the following programs, group together those that are equivalent in *Imp*. For example, if you think programs (a) through (h) are all equivalent to each other, but not to (i), your answer should look like this: {a,b,c,d,e,f,g,h} {i}.

- (a) WHILE X > 0 DO X := X + 1 END
- (b) IFB X = 0 THEN X := X + 1; Y := 1 ELSE Y := 0 FI; X := X Y; Y := 0
- (c) SKIP
- (d) WHILE X <> 0 DO X ::= X * Y + 1 END
- (e) Y := 0

```
(f) Y := X + 1; WHILE X <> Y DO Y := X + 1 END
(g) WHILE BTrue DO SKIP END
(h) WHILE X \ll X DO X := X + 1 END
(i) WHILE X \ll Y DO X := Y + 1 END
```

Here are some simple examples of equivalences of arithmetic and boolean expressions.

```
14.2.2
          Examples
Theorem aequiv_example:
  aequiv (AMinus (Ald X) (Ald X)) (ANum 0).
Proof.
  intros st. simpl. apply minus_diag.
Qed.
Theorem bequiv_example:
  bequiv (BEq (AMinus (Ald X) (Ald X)) (ANum 0)) BTrue.
Proof.
  intros st. unfold beval.
  rewrite aequiv_example. reflexivity.
Qed.
   For examples of command equivalence, let's start by looking at some trivial program
transformations involving SKIP:
Theorem skip_left: \forall c,
  cequiv
     (SKIP; c)
     c.
Proof.
  intros c st st'.
  split; intros H.
  Case "->".
    inversion H. subst.
    inversion H2. subst.
    assumption.
  Case "<-".
    apply E_Seq with st.
    apply E_Skip.
    assumption.
Qed.
```

Exercise: 2 stars (skip_right) Theorem skip_right: $\forall c$, cequiv

```
(c; \mathsf{SKIP})
c.

Proof.

Admitted.

Similarly, here is a simple transformations that simplifies \mathit{IFB} commands:

Theorem \mathsf{IFB\_true\_simple}: \, \forall \, c1 \, c2,
\mathsf{cequiv}

(IFB BTrue THEN c1 \, \mathsf{ELSE} \, c2 \, \mathsf{FI})
c1.

Proof.

intros c1 \, c2.
\mathsf{split}; \, \mathsf{intros} \, H.
\mathit{Case} \, "-> ".
\mathsf{inversion} \, H; \, \mathsf{subst.} \, \mathsf{assumption.} \, \mathsf{inversion} \, H5.
\mathit{Case} \, "< -".
\mathsf{apply} \, \mathsf{E\_lfTrue.} \, \mathsf{reflexivity.} \, \mathsf{assumption.} \, \mathsf{Qed.}
```

Of course, few programmers would be tempted to write a conditional whose guard is literally *BTrue*. A more interesting case is when the guard is *equivalent* to true:

Theorem: If b is equivalent to BTrue, then $IFB\ b\ THEN\ c1\ ELSE\ c2\ FI$ is equivalent to c1.

Proof:

• (\rightarrow) We must show, for all st and st, that if IFB b THEN c1 ELSE c2 FI / st || st, then c1 / st || st.

Proceed by cases on the rules that could possibly have been used to show IFB b THEN c1 ELSE c2 FI / st || st', namely E_IfTrue and $E_IfFalse$.

- Suppose the final rule rule in the derivation of IFB b THEN c1 ELSE c2 FI / $st \mid\mid st'$ was E_IfTrue . We then have, by the premises of E_IfTrue , that c1 / $st \mid\mid st'$. This is exactly what we set out to prove.
- On the other hand, suppose the final rule in the derivation of IFB b THEN c1 ELSE c2 FI / st || st' was E_IfFalse. We then know that beval st b = false and c2 / st || st'.

Recall that b is equivalent to BTrue, i.e. for all st, $beval\ st\ b = beval\ st\ BTrue$. In particular, this means that $beval\ st\ b = true$, since $beval\ st\ BTrue = true$. But this is a contradiction, since $E_IfFalse$ requires that $beval\ st\ b = false$. Thus, the final rule could not have been $E_IfFalse$.

• (\leftarrow) We must show, for all st and st', that if $c1 / st \mid\mid st$ ' then IFB b THEN c1 ELSE c2 FI $\mid st \mid\mid st$ '.

```
Since b is equivalent to BTrue, we know that beval st b = beval st BTrue = true.
     Together with the assumption that c1 / st \parallel st', we can apply E\_IfTrue to derive IFB
      b THEN c1 ELSE c2 FI / st || st'. \square
   Here is the formal version of this proof:
Theorem IFB_true: \forall b \ c1 \ c2,
     bequiv b BTrue \rightarrow
     cequiv
        (IFB b THEN c1 ELSE c2 FI)
        c1.
Proof.
  intros b c1 c2 Hb.
  split; intros H.
  Case "->".
    inversion H; subst.
    SCase "b evaluates to true".
       assumption.
    SCase "b evaluates to false (contradiction)".
      rewrite Hb in H5.

    rewrite Hb. reflexivity. Qed.
Exercise: 2 stars, recommended (IFB_false) Theorem IFB_false: \forall b \ c1 \ c2,
  bequiv b BFalse \rightarrow
  cequiv
    (IFB b THEN c1 ELSE c2 FI)
    c2.
Proof.
   Admitted.
   Exercise: 3 stars (swap_if_branches) Theorem swap_if_branches: \forall b \ e1 \ e2,
  cequiv
     (IFB b THEN e1 ELSE e2 FI)
    (IFB BNot b THEN e2 ELSE e1 FI).
Proof.
   Admitted.
   For WHILE loops, we can give a similar pair of theorems. A loop whose guard is
```

equivalent to BFalse is equivalent to SKIP, while a loop whose guard is equivalent to BTrue

is equivalent to $WHILE\ BTrue\ DO\ SKIP\ END$ (or any other non-terminating program). The first of these facts is easy.

```
Theorem WHILE_false : \forall b c,
     beguiv b BFalse \rightarrow
     cequiv
        (WHILE b DO c END)
       SKIP.
Proof.
  intros b c Hb. split; intros H.
  Case "->".
    inversion H; subst.
    SCase "E_WhileEnd".
      apply E_Skip.
    SCase "E_WhileLoop".
      rewrite Hb in H2. inversion H2.
  Case "<-".
    inversion H; subst.
    apply E_WhileEnd.
    rewrite Hb.
    reflexivity. Qed.
```

Exercise: 2 stars (WHILE_false_informal) Write an informal proof of WHILE_false.

To prove the second fact, we need an auxiliary lemma stating that WHILE loops whose guards are equivalent to BTrue never terminate:

Lemma: If b is equivalent to BTrue, then it cannot be the case that (WHILE b DO c END) / st || st'.

Proof: Suppose that $(WHILE\ b\ DO\ c\ END)\ /\ st\ ||\ st'.$ We show, by induction on a derivation of $(WHILE\ b\ DO\ c\ END)\ /\ st\ ||\ st',$ that this assumption leads to a contradiction.

- Suppose (WHILE b DO c END) / st || st' is proved using rule E_- WhileEnd. Then by assumption beval st b = false. But this contradicts the assumption that b is equivalent to BTrue.
- Suppose (WHILE b DO c END) / st || st' is proved using rule $E_-WhileLoop$. Then we are given the induction hypothesis that (WHILE b DO c END) / st || st' is contradictory, which is exactly what we are trying to prove!
- Since these are the only rules that could have been used to prove (WHILE b DO c END) / st || st', the other cases of the induction are immediately contradictory. \Box

```
\sim ( (WHILE b DO c END) / st | | st').

```

14.2.3 The Functional Equivalence Axiom

Finally, let's look at simple equivalences involving assignments. For example, we might expect to be able to show that X := AId X is equivalent to SKIP. However, when we try to show it, we get stuck in an interesting way.

```
\begin{split} \text{Theorem identity\_assignment\_first\_try} : & \forall \; (X \colon \mathbf{id}), \\ \text{cequiv} \; (X \colon := \mathsf{Ald} \; X) \; \mathsf{SKIP}. \\ \mathsf{Proof}. \\ & \text{intros. split}; \; \mathsf{intro} \; H. \\ & \textit{Case} \; "->". \\ & \text{inversion} \; H; \; \mathsf{subst. \; simpl.} \\ & \text{replace} \; (\mathsf{update} \; st \; X \; (st \; X)) \; \mathsf{with} \; st. \\ & \text{constructor.} \\ & \textit{Admitted.} \end{split}
```

What is going on here? Recall that our states are just functions from identifiers to values. For Coq, functions are only equal when their definitions are syntactically the same, modulo simplification. (This is the only way we can legally apply the $refl_-equal$ constructor of the inductively defined proposition eq!) In practice, for functions built up by repeated uses of the update operation, this means that two functions can be proven equal only if they were constructed using the $same\ update$ operations, applied in the same order. In the theorem above, the sequence of updates on the first parameter cequiv is one longer than for the second parameter, so it is no wonder that the equality doesn't hold.

This problem is actually quite general. If we try to prove other simple facts, such as cequiv (X ::= APlus (AId X ANum 1); X ::= APlus (AId X ANum 1)) (X ::= APlus (AId X ANum 2)) or cequiv (X ::= ANum 1; Y ::= ANum 2) (y ::= ANum 2; X ::= ANum 1) we'll get stuck in the same way: we'll have two functions that behave the same way on

we'll get stuck in the same way: we'll have two functions that behave the same way of all inputs, but cannot be proven to be eq to each other.

The reasoning principle we would like to use in these situations is called functional extensionality: for all x, f x = g x

f = g Although this principle is not derivable in Coq's built-in logic, it is safe to add it as an additional axiom.

```
Axiom functional_extensionality : \forall \{X \ Y : \mathtt{Type}\} \{f \ g : X \to Y\}, (\forall (x: X), f \ x = g \ x) \to f = g.
```

It can be shown that adding this axiom doesn't introduce any inconsistencies into Coq. (In this way, it is similar to adding one of the classical logic axioms, such as *excluded_middle*.) With the benefit of this axiom we can prove our theorem.

```
Theorem identity_assignment : \forall (X:id),
  cequiv
    (X ::= \mathsf{AId}\ X)
    SKIP.
Proof.
   intros. split; intro H.
      Case "->".
        inversion H; subst. simpl.
       replace (update st \ X \ (st \ X)) with st.
       constructor.
       apply functional_extensionality. intro.
       rewrite update_same; reflexivity.
      Case "<-".
        inversion H; subst.
       assert (st' = (update st' X (st' X))).
           apply functional_extensionality. intro.
           rewrite update_same; reflexivity.
       rewrite H0 at 2.
       constructor. reflexivity.
Qed.
Exercise: 2 stars, recommended (assign_aequiv) Theorem assign_aequiv: \forall X e,
  aequiv (Ald X) e \rightarrow
  cequiv SKIP (X := e).
Proof.
   Admitted.
```

Exercise: 2 stars, optional (functional_extensionality_failed_false) As we just mentioned, functional extensionality doesn't add any inconsistencies into Coq. However, consider the following theorem. Inspired by it, we present an attempt to prove *False*. Briefly explain why it will fail.

```
Theorem feff_1 : true = false \rightarrow False.
```

```
Proof. intros. inversion H. Qed. Lemma feff_2: empty_state = update empty_state X 0. Proof. apply functional_extensionality. intros. destruct x as [n]. destruct n as [n]. Case "x = AId 0". reflexivity. Case "x = AId (S n')". reflexivity. Qed.
```

If we were able to prove $feff_{-}3$, then together with $feff_{-}2$, a proof of False is immediate. Explain why the inversion H fails, though it works in $feff_{-}1$.

14.3 Properties of Behavioral Equivalence

We now turn to developing some of the properties of the program equivalences we have defined.

14.3.1 Behavioral Equivalence is an Equivalence

First, we verify that the equivalences on aexps, bexps, and coms really are equivalences – i.e., that they are reflexive, symmetric, and transitive:

```
Lemma refl_aequiv : \forall (a : \mathbf{aexp}), aequiv a \cdot a.
Proof.
   intros a st. reflexivity. Qed.
Lemma sym_aequiv : \forall (a1 \ a2 : \mathbf{aexp}),
   aequiv a1 \ a2 \rightarrow \text{aequiv } a2 \ a1.
Proof.
   intros a1 a2 H. intros st. symmetry. apply H. Qed.
Lemma trans_aequiv : \forall (a1 \ a2 \ a3 : \mathbf{aexp}),
   aequiv a1 a2 \rightarrow aequiv a2 a3 \rightarrow aequiv a1 a3.
Proof.
  unfold aequiv. intros a1 a2 a3 H12 H23 st.
   rewrite (H12 \ st). rewrite (H23 \ st). reflexivity. Qed.
Lemma refl_bequiv : \forall (b : \mathbf{bexp}), bequiv b \ b.
Proof.
   unfold bequiv. intros b st. reflexivity. Qed.
Lemma sym_bequiv : \forall (b1 \ b2 : \mathbf{bexp}),
   beguiv b1 b2 \rightarrow \text{beguiv } b2 b1.
```

```
Proof.
  unfold bequiv. intros b1 b2 H. intros st. symmetry. apply H. Qed.
Lemma trans_bequiv : \forall (b1 \ b2 \ b3 : \mathbf{bexp}),
  beguiv b1 \ b2 \rightarrow \text{beguiv } b2 \ b3 \rightarrow \text{beguiv } b1 \ b3.
Proof.
  unfold bequiv. intros b1 b2 b3 H12 H23 st.
  rewrite (H12 \ st). rewrite (H23 \ st). reflexivity. Qed.
Lemma refl_cequiv : \forall (c : com), cequiv c c.
Proof.
  unfold cequiv. intros c st st. apply iff_refl. Qed.
Lemma sym_cequiv : \forall (c1 c2 : com),
  cequiv c1 c2 \rightarrow cequiv c2 c1.
Proof.
  unfold cequiv. intros c1 c2 H st st'.
  assert (c1 / st \mid \mid st' \leftrightarrow c2 / st \mid \mid st') as H'.
     SCase "Proof of assertion". apply H.
  apply iff_sym. assumption.
Qed.
Lemma iff_trans : \forall (P1 \ P2 \ P3 : Prop),
  (P1 \leftrightarrow P2) \rightarrow (P2 \leftrightarrow P3) \rightarrow (P1 \leftrightarrow P3).
Proof.
  intros P1 P2 P3 H12 H23.
  inversion H12. inversion H23.
  split; intros A.
     apply H1. apply H. apply A.
     apply H0. apply H2. apply A. Qed.
Lemma trans_cequiv : \forall (c1 \ c2 \ c3 : \mathbf{com}),
  cequiv c1 c2 \rightarrow cequiv c2 c3 \rightarrow cequiv c1 c3.
Proof.
  unfold cequiv. intros c1 c2 c3 H12 H23 st st'.
  apply iff_trans with (c2 / st \mid \mid st'). apply H12. apply H23. Qed.
```

14.3.2 Behavioral Equivalence is a Congruence

Less obviously, behavioral equivalence is also a *congruence*. That is, the equivalence of two subprograms implies the equivalence of the larger programs in which they are embedded: aequiv a1 a1'

```
cequiv (i ::= a1) (i ::= a1')
cequiv c1 c1' cequiv c2 c2'
```

cequiv (c1;c2) (c1';c2') ...and so on. (Note that we are using the inference rule notation here not as part of a definition, but simply to write down some valid implications in a readable format. We prove these implications below.)

We will see a concrete example of why these congruence properties are important in the following section (in the proof of *fold_constants_com_sound*), but the main idea is that they allow us to replace a small part of a large program with an equivalent small part and know that the whole large programs are equivalent *without* doing an explicit proof about the non-varying parts – i.e., the "proof burden" of a small change to a large program is proportional to the size of the change, not the program.

```
Theorem CAss_congruence : ∀ i a1 a1',
    aequiv a1 a1' →
    cequiv (CAss i a1) (CAss i a1').

Proof.
    intros i a1 a2 Heqv st st'.
    split; intros Hceval.
    Case "->".
        inversion Hceval. subst. apply E_Ass.
        rewrite Heqv. reflexivity.
    Case "<-".
        inversion Hceval. subst. apply E_Ass.
        rewrite Heqv. reflexivity. Qed.
```

The congruence property for loops is a little more interesting, since it requires induction. Theorem: Equivalence is a congruence for WHILE – that is, if b1 is equivalent to b1' and c1 is equivalent to c1', then WHILE b1 DO c1 END is equivalent to WHILE b1' DO c1' END.

Proof: Suppose b1 is equivalent to b1' and c1 is equivalent to c1'. We must show, for every st and st', that WHILE b1 DO c1 END / st || st' iff WHILE b1' DO c1' END / st || st'. We consider the two directions separately.

- (→) We show that WHILE b1 DO c1 END / st || st' implies WHILE b1' DO c1' END / st || st', by induction on a derivation of WHILE b1 DO c1 END / st || st'. The only nontrivial cases are when the final rule in the derivation is E_WhileEnd or E_WhileLoop.
 - $E_-WhileEnd$: In this case, the form of the rule gives us beval st b1 = false and st = st'. But then, since b1 and b1' are equivalent, we have beval st b1' = false, and $E_-WhileEnd$ applies, giving us WHILE b1' DO c1' END / st || st', as required.
 - $E_WhileLoop$: The form of the rule now gives us beval st b1 = true, with $c1 / st \mid\mid st'0$ and WHILE b1 DO c1 END / st'0 $\mid\mid st'$ for some state st'0, with the induction hypothesis WHILE b1' DO c1' END / $st'0 \mid\mid st'$.
 - Since c1 and c1' are equivalent, we know that c1' / $st \mid\mid st'0$. And since b1 and b1' are equivalent, we have $beval\ st\ b1$ ' = true. Now E-WhileLoop applies, giving us WHILE b1' DO c1' END / $st \mid\mid st$ ', as required.

```
Theorem CWhile_congruence : \forall b1 \ b1' \ c1 \ c1',
  bequiv b1\ b1' \rightarrow \text{cequiv } c1\ c1' \rightarrow
  cequiv (WHILE b1 DO c1 END) (WHILE b1' DO c1' END).
Proof.
  unfold bequiv, cequiv.
  intros b1 b1' c1 c1' Hb1e Hc1e st st'.
  split; intros Hce.
  Case "->".
    remember (WHILE b1 DO c1 END) as cwhile.
    induction Hce; inversion Heqcwhile; subst.
    SCase "E_WhileEnd".
       apply E_WhileEnd. rewrite \leftarrow Hb1e. apply H.
    SCase "E_WhileLoop".
       apply E_WhileLoop with (st':=st').
       SSCase "show loop runs". rewrite \leftarrow Hb1e. apply H.
       SSCase "body execution".

  bequiv b b' \rightarrow \text{cequiv } c1 c1' \rightarrow \text{cequiv } c2 c2' \rightarrow
  cequiv (IFB b THEN c1 ELSE c2 FI) (IFB b' THEN c1' ELSE c2' FI).
Proof.
   Admitted.
   For example, here are two equivalent programs and a proof of their equivalence...
Example congruence_example:
  cequiv
    (X ::= ANum 0;
     IFB (BEq (Ald X) (ANum 0))
     THEN
        Y ::= ANum 0
     FLSF.
        Y ::= ANum 42
     FI)
     (X ::= ANum 0;
     IFB (BEq (Ald X) (ANum 0))
     THEN
        Y ::= AMinus (Ald X) (Ald X)
     ELSE
        Y ::= ANum 42
     FI).
Proof.
  apply CSeq_congruence.
    apply refl_cequiv.
    apply Clf_congruence.
      apply refl_bequiv.
      apply CAss_congruence. unfold aequiv. simpl.
         symmetry. apply minus_diag.
      apply refl_cequiv.
Qed.
```

14.4 Case Study: Constant Folding

A program transformation is a function that takes a program as input and produces some variant of the program as its output. Compiler optimizations such as constant folding are a canonical example, but there are many others.

14.4.1 Soundness of Program Transformations

A program transformation is *sound* if it preserves the behavior of the original program.

We can define a notion of soundness for translations of aexps, bexps, and coms.

```
Definition atrans_sound (atrans: aexp \rightarrow aexp): Prop := \forall (a: aexp), aequiv a (atrans a).
Definition btrans_sound (btrans: bexp \rightarrow bexp): Prop := \forall (b: bexp), bequiv b (btrans b).
Definition ctrans_sound (ctrans: com \rightarrow com): Prop := \forall (c: com), cequiv c (ctrans c).
```

14.4.2 The Constant-Folding Transformation

An expression is *constant* when it contains no variable references.

Constant folding is an optimization that finds constant expressions and replaces them by their values.

```
Fixpoint fold_constants_aexp (a : aexp) : aexp :=
  match a with
   ANum n \Rightarrow ANum n
   Ald i \Rightarrow Ald i
  | APIus a1 a2 \Rightarrow
       match (fold_constants_aexp a1, fold_constants_aexp a2) with
       (ANum n1, ANum n2) \Rightarrow ANum (n1 + n2)
       (a1', a2') \Rightarrow APlus a1' a2'
       end
  | AMinus a1 \ a2 \Rightarrow
       match (fold_constants_aexp a1, fold_constants_aexp a2) with
       (ANum n1, ANum n2) \Rightarrow ANum (n1 - n2)
       (a1', a2') \Rightarrow AMinus a1' a2'
       end
  | AMult a1 \ a2 \Rightarrow
       match (fold_constants_aexp a1, fold_constants_aexp a2) with
       (ANum n1, ANum n2) \Rightarrow ANum (n1 \times n2)
       (a1', a2') \Rightarrow \mathsf{AMult} \ a1' \ a2'
       end
  end.
Example fold_aexp_ex1 :
    fold_constants_aexp
       (AMult (APlus (ANum 1) (ANum 2)) (Ald X))
  = AMult (ANum 3) (Ald X).
Proof. reflexivity. Qed.
```

Note that this version of constant folding doesn't eliminate trivial additions, etc. – we are focusing attention on a single optimization for the sake of simplicity. It is not hard to incorporate other ways of simplifying expressions; the definitions and proofs just get longer.

```
Example fold_aexp_ex2 :
    fold_constants_aexp
        (AMinus (Ald X) (APlus (AMult (ANum 0) (ANum 6)) (Ald Y)))
        = AMinus (Ald X) (APlus (ANum 0) (Ald Y)).
Proof. reflexivity. Qed.
```

Not only can we lift $fold_constants_aexp$ to bexps (in the BEq and BLe cases), we can also find constant boolean expressions and reduce them in-place.

```
Fixpoint fold_constants_bexp (b : \mathbf{bexp}) : \mathbf{bexp} :=
  \mathtt{match}\ b with
    BTrue \Rightarrow BTrue
    BFalse \Rightarrow BFalse
   BEq a1 \ a2 \Rightarrow
        match (fold_constants_aexp a1, fold_constants_aexp a2) with
        (ANum n1, ANum n2) \Rightarrow if beq_nat n1 n2 then BTrue else BFalse
        (a1', a2') \Rightarrow BEq a1' a2'
        end
  | BLe a1 a2 \Rightarrow
        match (fold_constants_aexp a1, fold_constants_aexp a2) with
        (ANum n1, ANum n2) \Rightarrow if ble_nat n1 n2 then BTrue else BFalse
        |(a1', a2') \Rightarrow BLe a1' a2'
        end
  | BNot b1 \Rightarrow
        match (fold_constants_bexp b1) with
         \mathsf{BTrue} \Rightarrow \mathsf{BFalse}
         BFalse \Rightarrow BTrue
        |b1' \Rightarrow \mathsf{BNot}\ b1'
        end
  | BAnd b1 b2 \Rightarrow
        match (fold_constants_bexp b1, fold_constants_bexp b2) with
        | (BTrue, BTrue) \Rightarrow BTrue
        | (BTrue, BFalse) \Rightarrow BFalse
        | (BFalse, BTrue) \Rightarrow BFalse
        | (BFalse, BFalse) \Rightarrow BFalse
        (b1', b2') \Rightarrow \mathsf{BAnd}\ b1'\ b2'
        end
  end.
Example fold_bexp_ex1 :
     fold_constants_bexp (BAnd BTrue (BNot (BAnd BFalse BTrue)))
```

```
= BTrue.
Proof. reflexivity. Qed.
Example fold_bexp_ex2:
     fold_constants_bexp
       (BAnd (BEq (Ald X) (Ald Y))
               (\mathsf{BEq}\ (\mathsf{ANum}\ 0)
                     (AMinus (ANum 2) (APlus (ANum 1) (ANum 1)))))
  = BAnd (BEq (Ald X) (Ald Y)) BTrue.
Proof. reflexivity. Qed.
   To fold constants in a command, we apply the appropriate folding functions on all em-
bedded expressions.
Fixpoint fold_constants_com (c : com) : com :=
  match c with
  \mid SKIP \Rightarrow
       SKIP
  |i::=a\Rightarrow
       CAss i (fold_constants_aexp a)
  | c1 ; c2 \Rightarrow
       (fold_constants_com c1); (fold_constants_com c2)
  | IFB b THEN c1 ELSE c2 FI \Rightarrow
       match fold_constants_bexp b with
         BTrue \Rightarrow fold_constants_com c1
         BFalse \Rightarrow fold_constants_com c2
       |b' \Rightarrow \text{IFB } b' \text{ THEN fold\_constants\_com } c1
                          ELSE fold_constants_com c2 FI
       end
  | WHILE b DO c END \Rightarrow
       match fold_constants_bexp b with
         BTrue ⇒ WHILE BTrue DO SKIP END
        \mathsf{BFalse} \Rightarrow \mathsf{SKIP}
       |b' \Rightarrow \text{WHILE } b' \text{ DO (fold\_constants\_com } c) \text{ END}
       end
  end.
Example fold_com_ex1:
  fold_constants_com
     (X ::= APlus (ANum 4) (ANum 5);
      Y ::= AMinus (Ald X) (ANum 3);
      IFB BEq (AMinus (Ald X) (Ald Y)) (APlus (ANum 2) (ANum 4)) THEN
        SKIP
      FLSF.
        Y ::= ANum 0
```

```
FI;
     IFB BLe (ANum 0) (AMinus (ANum 4) (APlus (ANum 2) (ANum 1))) THEN
       Y ::= ANum 0
     ELSE
       SKIP
     FI;
     WHILE BEq (Ald Y) (ANum 0) DO
       X ::= APlus (Ald X) (ANum 1)
     END) =
  (X ::= ANum 9;
  Y ::= AMinus (Ald X) (ANum 3);
   IFB BEq (AMinus (Ald X) (Ald Y)) (ANum 6) THEN
     SKIP
  ELSE
     (Y ::= ANum 0)
  FI;
  Y ::= ANum 0;
  WHILE BEq (Ald Y) (ANum 0) DO
     X ::= APlus (Ald X) (ANum 1)
  END).
Proof. reflexivity. Qed.
```

14.4.3 Soundness of Constant Folding

Now we need to show that what we've done is correct. Here's the proof for arithmetic expressions:

```
Theorem fold_constants_aexp_sound:
   atrans_sound fold_constants_aexp.

Proof.
   unfold atrans_sound. intros a. unfold aequiv. intros st.
   aexp_cases (induction a) Case; simpl;

   try reflexivity;

   try (destruct (fold_constants_aexp a1);
      destruct (fold_constants_aexp a2);
      rewrite IHa1; rewrite IHa2; reflexivity). Qed.
```

Exercise: 3 stars, optional (fold_bexp_BEq_informal) Here is an informal proof of the BEq case of the soundness argument for boolean expression constant folding. Read it carefully and compare it to the formal proof that follows. Then fill in the BLe case of the formal proof (without looking at the BEq case, if possible).

Theorem: The constant folding function for booleans, $fold_constants_bexp$, is sound. Proof: We must show that b is equivalent to $fold_constants_bexp$, for all boolean expressions b. Proceed by induction on b. We show just the case where b has the form BEq a1 a2

In this case, we must show beval st (BEq a1 a2) = beval st (fold_constants_bexp (BEq a1 a2)). There are two cases to consider:

• First, suppose $fold_constants_aexp$ a1 = ANum n1 and $fold_constants_aexp$ a2 = ANum n2 for some n1 and n2.

In this case, we have fold_constants_bexp (BEq a1 a2) = if beq_nat n1 n2 then BTrue else BFalse and beval st (BEq a1 a2) = beq_nat (aeval st a1) (aeval st a2). By the soundness of constant folding for arithmetic expressions (Lemma fold_constants_aexp_sound), we know aeval st a1 = aeval st (fold_constants_aexp a1) = aeval st (ANum n1) = n1 and aeval st a2 = aeval st (fold_constants_aexp a2) = aeval st (ANum n2) = n2, so beval st (BEq a1 a2) = beq_nat (aeval a1) (aeval a2) = beq_nat n1 n2. Also, it is easy to see (by considering the cases n1 = n2 and $n1 \neq n2$ separately) that beval st (if beq_nat n1 n2 then BTrue else BFalse) = if beq_nat n1 n2 then beval st BTrue else beval st BFalse = if beq_nat n1 n2 then true else false = beq_nat n1 n2. So beval st (BEq a1 a2) = beq_nat n1 n2. = beval st (if beq_nat n1 n2 then BTrue else BFalse),

]] as required.

• Otherwise, one of $fold_constants_aexp\ a1$ and $fold_constants_aexp\ a2$ is not a constant. In this case, we must show beval st (BEq a1 a2) = beval st (BEq (fold_constants_aexp a1) (fold_constants_aexp a2)), which, by the definition of beval, is the same as showing beq_nat (aeval st a1) (aeval st a2) = beq_nat (aeval st (fold_constants_aexp a1)) (aeval st (fold_constants_aexp a2)). But the soundness of constant folding for arithmetic expressions ($fold_constants_aexp_sound$) gives us aeval st a1 = aeval st (fold_constants_aexp a1) aeval st a2 = aeval st (fold_constants_aexp a2), completing the case. \square

```
Theorem fold_constants_bexp_sound:
   btrans_sound fold_constants_bexp.

Proof.
   unfold btrans_sound. intros b. unfold bequiv. intros st.

Soundness of (0 + n) Elimination, Redux

Exercise: 4 stars, optional (optimize_Oplus) Recall the definition optimize_Oplus from Imp.v: Fixpoint optimize_Oplus (e:aexp): aexp:= match e with | ANum n => ANum n | APlus (ANum 0) e2 => optimize_Oplus e2 | APlus e1 e2 => APlus (optimize_Oplus e1) (optimize_Oplus e2) | AMinus e1 e2 => AMinus (optimize_Oplus e1) (optimize_Oplus e2) | AMult e1 e2 => AMult (optimize_Oplus e1) (optimize_Oplus e2) end. Note that this function is defined over the old aexps, without states.

Write a new version of this function that accounts for variables, and analogous ones for bexps and commands: optimize_0plus_aexp optimize_0plus_bexp optimize_0plus_com Prove that these three functions are sound, as we did for $fold_constants_\times$. Make sure you use the congruence lemmas in the proof of $optimize_0plus_com$ (otherwise it will be long!).

Then define an optimizer on commands that first folds constants (using $fold_constants_com$) and then eliminates 0 + n terms (using $optimize_oplus_com$).

- Give a meaningful example of this optimizer's output.
- Prove that the optimizer is sound. (This part should be *very* easy.)

14.5 Proving That Programs Are *Not* Equivalent

Suppose that c1 is a command of the form X := a1; Y := a2 and c2 is the command X := a1; Y := a2, where a2 is formed by substituting a1 for all occurrences of X in a2. For example, c1 and c2 might be: c1 = (X := 42 + 53; Y := Y + X) c2 = (X := 42 + 53; Y := Y + (42 + 53)) Clearly, this particular c1 and c2 are equivalent. Is this true in general?

We will see in a moment that it is not, but it is worthwhile to pause, now, and see if you can find a counter-example on your own.

Here, formally, is the function that substitutes an arithmetic expression for each occurrence of a given variable in another expression:

```
Fixpoint subst_aexp (i: id) (u: aexp) (a: aexp): aexp:= match a with | ANum n \Rightarrow ANum n | Ald i' \Rightarrow if beq_id i i' then u else Ald i' | APlus a1 a2 \Rightarrow APlus (subst_aexp i u a1) (subst_aexp i u a2) | AMinus a1 a2 \Rightarrow AMinus (subst_aexp i u a1) (subst_aexp i u a2)
```

```
| AMult a1 a2 \Rightarrow AMult (subst_aexp i u a1) (subst_aexp i u a2) end.

Example subst_aexp_ex:
  subst_aexp X (APlus (ANum 42) (ANum 53)) (APlus (Ald Y) (Ald X)) = (APlus (Ald Y) (APlus (ANum 42) (ANum 53))).

Proof. reflexivity. Qed.
```

And here is the property we are interested in, expressing the claim that commands c1 and c2 as described above are always equivalent.

```
\begin{array}{lll} {\tt Definition \ subst\_equiv\_property} := \forall \ i1 \ i2 \ a1 \ a2, \\ {\tt cequiv} \ (i1 \ ::= a1 \ ; \ i2 \ ::= a2) \\ & (i1 \ ::= a1 \ ; \ i2 \ ::= {\tt subst\_aexp} \ i1 \ a1 \ a2). \end{array}
```

Sadly, the property does *not* always hold.

Theorem: It is not the case that, for all i1, i2, a1, and a2, cequiv (i1 ::= a1; i2 ::= a2) (i1 ::= a1; i2 ::= subst_aexp i1 a1 a2).]] Proof: Suppose, for a contradiction, that for all i1, i2, a1, and a2, we have cequiv (i1 ::= a1; i2 ::= a2) (i1 ::= a1; i2 ::= subst_aexp i1 a1 a2). Consider the following program: X ::= APlus (AId X) (ANum 1); Y ::= AId X Note that (X ::= APlus (AId X) (ANum 1); Y ::= AId X) / empty_state || st1, where $st1 = \{X | -> 1, Y | -> 1\}$.

By our assumption, we know that cequiv (X ::= APlus (AId X) (ANum 1); Y ::= AId X) (X ::= APlus (AId X) (ANum 1); Y ::= APlus (AId X) (ANum 1)) so, by the definition of cequiv, we have (X ::= APlus (AId X) (ANum 1); Y ::= APlus (AId X) (ANum 1)) / empty_state || st1. But we can also derive (X ::= APlus (AId X) (ANum 1); Y ::= APlus (AId X) (ANum 1)) / empty_state || st2, where $st2 = \{ X \mid -> 1, Y \mid -> 2 \}$. Note that $st1 \neq st2$; this is a contradiction, since ceval is deterministic! \square

```
Theorem subst_inequiv :
```

```
¬ subst_equiv_property.
Proof.
  unfold subst_equiv_property.
  intros Contra.
  remember (X ::= APlus (Ald X) (ANum 1);
             Y ::= Ald X
      as c1.
  remember (X ::= APlus (Ald X) (ANum 1);
             Y ::= APlus (Ald X) (ANum 1)
      as c2.
  assert (cequiv c1 c2) by (subst; apply Contra).
  remember (update (update empty_state X 1) Y 1) as st1.
  remember (update (update empty_state X 1) Y 2) as st2.
  assert (H1: c1 / empty_state | | st1);
  assert (H2: c2 / empty_state | | st2);
  try (subst;
```

```
apply E_Seq with (st' := (update empty_state X 1));
     apply E_Ass; reflexivity).
apply H in H1.
assert (Hcontra: st1 = st2)
  by (apply (ceval_deterministic c2 empty_state); assumption).
assert (Hcontra': st1 Y = st2 Y)
  by (rewrite Hcontra; reflexivity).
subst. inversion Hcontra'. Qed.
```

Exercise: 4 stars, optional (better_subst_equiv) The equivalence we had in mind above was not complete nonsense – it was actually almost right. To make it correct, we just need to exclude the case where the variable X occurs in the right-hand-side of the first assignment statement.

```
Inductive var\_not\_used\_in\_aexp (X:id): aexp \rightarrow Prop :=

  aeval (update st \ i \ ni) a = aeval \ st \ a.
Proof.
    Admitted.
    Using var\_not\_used\_in\_aexp, formalize and prove a correct verson of subst\_equiv\_property.
   Exercise: 3 stars, recommended (inequiv_exercise) Theorem inequiv_exercise:
```

→ cequiv (WHILE BTrue DO SKIP END) SKIP.

Proof.

Admitted.

14.6 Extended exercise: Non-deterministic Imp

As we have seen (in theorem $ceval_deterministic$ in the Imp chapter), Imp's evaluation relation is deterministic. However, non-determinism is an important part of the definition of many real programming languages. For example, in many imperative languages (such as C and its relatives), the order in which function arguments are evaluated is unspecified. The program fragment x = 0; f(++x, x); might call f with arguments (1, 0) or (1, 1), depending how the compiler chooses to order things. This can be a little confusing for programmers, but it gives the compiler writer useful freedom.

In this exercise, we will extend Imp with a simple non-deterministic command and study how this change affects program equivalence. The new command has the syntax HAVOC X, where X is an identifier. The effect of executing HAVOC X is to assign an arbitrary number to the variable X, non-deterministically. For example, after executing the program: HAVOC Y; Z := Y * 2 the value of Y can be any number, while the value of Z is twice that of Y (so Z is always even). Note that we are not saying anything about the /probabilities/ of the outcomes – just that there are (infinitely) many different outcomes that can possibly happen after executing this non-deterministic code.

In a sense a variable on which we do *HAVOC* roughly corresponds to an unitialized variable in the C programming language. After the *HAVOC* the variable holds a fixed but arbitrary number. Most sources of nondeterminism in language definitions are there precisely because programmers don't care which choice is made (and so it is good to leave it open to the compiler to choose whichever will run faster).

We call this new language Himp ("Imp extended with HAVOC").

Module HIMP.

To formalize the language, we first add a clause to the definition of commands.

```
Inductive com: Type:=  | \ \mathsf{CSkip} : \ \mathsf{com} \\ | \ \mathsf{CAss} : \ \mathsf{id} \to \mathsf{aexp} \to \mathsf{com} \\ | \ \mathsf{CSeq} : \ \mathsf{com} \to \mathsf{com} \to \mathsf{com} \\ | \ \mathsf{CIf} : \ \mathsf{bexp} \to \mathsf{com} \to \mathsf{com} \to \mathsf{com} \\ | \ \mathsf{CWhile} : \ \mathsf{bexp} \to \mathsf{com} \to \mathsf{com} \\ | \ \mathsf{CWhile} : \ \mathsf{bexp} \to \mathsf{com} \to \mathsf{com} \\ | \ \mathsf{CHavoc} : \ \mathsf{id} \to \mathsf{com} . \\ | \ \mathsf{CHavoc} : \ \mathsf{id} \to \mathsf{com} . \\ | \ \mathsf{Tactic} \ \mathsf{Notation} \ "\mathsf{com\_cases}" \ \mathit{tactic}(\mathsf{first}) \ \mathit{ident}(c) := \\ | \ \mathsf{first}; \\ | \ \mathsf{Case\_aux} \ c \ "\mathsf{SKIP}" \ | \ \mathsf{Case\_aux} \ c \ "::=" \ | \ \mathsf{Case\_aux} \ c \ ";" \\ | \ \mathsf{Case\_aux} \ c \ "\mathsf{IFB}" \ | \ \mathsf{Case\_aux} \ c \ "\mathsf{WHILE}" \ | \ \mathsf{Case\_aux} \ c \ "\mathsf{HAVOC}" \ ]. \\ | \ \mathsf{Notation} \ "\mathsf{SKIP}" := \\ | \ \mathsf{CSkip}. \\ | \ \mathsf{Notation} \ "\mathsf{X} \ ":=" \ \mathsf{a}" := \\ | \ \mathsf{CSkip} := \\ | \ \mathsf{Notation} \ "\mathsf{X} \ ":=" \ \mathsf{a}" := \\ | \ \mathsf{CSkip} := \\ | \ \mathsf{CSki
```

```
(CAss X a) (at level 60). Notation "c1; c2" := (CSeq c1 c2) (at level 80, right associativity). Notation "'WHILE' b 'DO' c 'END'" := (CWhile b c) (at level 80, right associativity).    | Case_aux c "E_WhileEnd" | Case_aux c "E_WhileLoop"
```

```
].
   As a sanity check, the following claims should be provable for your definition:
Example havoc_example1 : (HAVOC X) / empty_state | | update empty_state X 0.
Proof.
   Admitted.
Example havoc_example2:
  (SKIP; HAVOC Z) / empty_state | | update empty_state Z 42.
Proof.
   Admitted.
   Finally, we repeat the definition of command equivalence from above:
Definition cequiv (c1 \ c2 : \mathbf{com}) : \mathsf{Prop} := \forall \ st \ st' : \mathsf{state},
  c1 / st \mid \mid st' \leftrightarrow c2 / st \mid \mid st'.
   This definition still makes perfect sense in the case of always terminating programs, so
let's apply it to prove some non-deterministic programs equivalent or non-equivalent.
Exercise: 3 stars (havoc_swap) Are the following two programs equivalent?
Definition pXY :=
  HAVOC X; HAVOC Y.
Definition pYX :=
  HAVOC Y; HAVOC X.
   If you think they are equivalent, prove it. If you think they are not, prove that.
Theorem pXY_cequiv_pYX:
  cequiv pXY pYX ∨ ¬cequiv pXY pYX.
Proof. Admitted.
Exercise: 4 stars (havoc_copy) Are the following two programs equivalent?
Definition ptwice :=
  HAVOC X; HAVOC Y.
Definition pcopy :=
  HAVOC X; Y ::= Ald X.
   If you think they are equivalent, then prove it. If you think they are not, then prove
that. (Hint: You may find the assert tactic useful.)
Theorem ptwice_cequiv_pcopy:
  cequiv ptwice pcopy ∨ ¬cequiv ptwice pcopy.
Proof. Admitted.
```

The definition of program equivalence we are using here has some subtle consequences on programs that may loop forever. What *cequiv* says is that the set of possible *terminating* outcomes of two equivalent programs is the same. However, in a language with non-determinism, like Himp, some programs always terminate, some programs always diverge, and some programs can non-deterministically terminate in some runs and diverge in others. The final part of the following optional exercise illustrates this phenomenon.

Exercise: 5 stars, optional (havoc_diverge) Prove the following program equivalences and non-equivalences, and try to understand why the *cequiv* definition has the behavior it has on these examples.

```
Definition p1 : com :=
  WHILE (BNot (BEq (Ald X) (ANum 0))) DO
    HAVOC Y;
    X ::= APlus (Ald X) (ANum 1)
  END.
Definition p2 : com :=
  WHILE (BNot (BEq (Ald X) (ANum 0))) DO
    SKIP
  END.
Theorem p1_p2_equiv : cequiv p1 p2.
Proof. Admitted.
Definition p3 : com :=
  Z ::= ANum 1;
  WHILE (BNot (BEq (Ald X) (ANum 0))) DO
    HAVOC X;
    HAVOC Z
  END.
Definition p4 : com :=
  X ::= (ANum \ 0);
  Z ::= (ANum 1).
Theorem p3_p4_inequiv : ¬ cequiv p3 p4.
Proof. Admitted.
Definition p5 : com :=
  WHILE (BNot (BEq (Ald X) (ANum 1))) DO
    HAVOC X
 END.
Definition p6 : com :=
  X ::= ANum 1.
Theorem p5_p6_equiv : cequiv p5 p6.
Proof. Admitted.
```

□ End HIMP.

14.7 Doing Without Extensionality (Optional)

Purists might object to using the functional_extensionality axiom. In general, it can be quite dangerous to add axioms, particularly several at once (as they may be mutually inconsistent). In fact, functional_extensionality and excluded_middle can both be assumed without any problems, but some Coq users prefer to avoid such "heavyweight" general techniques, and instead craft solutions for specific problems that stay within Coq's standard logic.

For our particular problem here, rather than extending the definition of equality to do what we want on functions representing states, we could instead give an explicit notion of equivalence on states. For example:

```
Definition stequiv (st1 \ st2 : state) : Prop := \forall (X:\mathbf{id}), st1 \ X = st2 \ X.
Notation "st1 '~' st2" := (stequiv st1 \ st2) (at level 30).
```

It is easy to prove that *stequiv* is an *equivalence* (i.e., it is reflexive, symmetric, and transitive), so it partitions the set of all states into equivalence classes.

```
Exercise: 1 star, optional (stequiv_refl) Lemma stequiv_refl: \forall (st: state),
  st \neg st.
Proof.
   Admitted.
   Exercise: 1 star, optional (stequiv_sym) Lemma stequiv_sym : \forall (st1 st2 : state),
  st1 \neg st2 \rightarrow
  st2 \neg st1.
Proof.
   Admitted.
   Exercise: 1 star, optional (stequiv_trans) Lemma stequiv_trans: \forall (st1 st2 st3:
state).
  st1 \neg st2 \rightarrow
  st2 \neg st3 \rightarrow
  st1 \neg st3.
Proof.
    Admitted.
   Another useful fact...
```

```
Exercise: 1 star, optional (stequiv_update) Lemma stequiv_update: \forall (st1 st2: state),
  st1 \neg st2 \rightarrow
  \forall (X:id) (n:nat),
  update st1 \ X \ n \neg update \ st2 \ X \ n.
Proof.
   Admitted.
   It is then straightforward to show that aeval and beval behave uniformly on all members
of an equivalence class:
Exercise: 2 stars, optional (stequiv_aeval) Lemma stequiv_aeval : \forall (st1 st2 : state),
  st1 \neg st2 \rightarrow
  \forall (a:aexp), aeval st1 a = aeval st2 a.
Proof.
   Admitted.
   Exercise: 2 stars, optional (stequiv_beval) Lemma stequiv_beval: \forall (st1 st2: state),
  st1 \neg st2 \rightarrow
  \forall (b: \mathbf{bexp}), \text{ beval } st1 \ b = \text{ beval } st2 \ b.
Proof.
   Admitted.
   We can also characterize the behavior of ceval on equivalent states (this result is a bit
more complicated to write down because ceval is a relation).
Lemma stequiv_ceval: \forall (st1 \ st2 : state),
  st1 \neg st2 \rightarrow
  \forall (c: com) (st1': state),
     (c \mid st1 \mid \mid st1') \rightarrow
     \exists st2': state,
     ((c / st2 || st2') \wedge st1' \neg st2').
Proof.
  intros st1 st2 STEQV c st1' CEV1. generalize dependent st2.
  induction CEV1; intros st2 STEQV.
  Case "SKIP".
     \exists st2. split.
       constructor.
       assumption.
  Case ":=".
     \exists (update st2 \ X \ n). split.
        constructor. rewrite \leftarrow H. symmetry. apply stequiv_aeval.
        assumption. apply stequiv_update. assumption.
```

```
Case ";".
    destruct (IHCEV1\_1 \ st2 \ STEQV) as [st2' \ [P1 \ EQV1]].
    destruct (IHCEV1_2 st2' EQV1) as [st2'' [P2 EQV2]].
    \exists st2". split.
      apply E_Seq with st2'; assumption.
      assumption.
  Case "IfTrue".
    destruct (IHCEV1 \ st2 \ STEQV) as [st2' \ [P \ EQV]].
    \exists st2'. split.
      apply E_I fTrue. rewrite \leftarrow H. symmetry. apply stequiv_beval.
      assumption. assumption. assumption.
  Case "IfFalse".
    destruct (IHCEV1 \ st2 \ STEQV) as [st2' \ [P \ EQV]].
    \exists st2'. split.
     apply E_lfFalse. rewrite \leftarrow H. symmetry. apply stequiv_beval.
     assumption. assumption. assumption.
  Case "WhileEnd".

      apply E_WhileEnd. rewrite ← H. symmetry. apply stequiv_beval.
      assumption. assumption.
  Case "WhileLoop".
    destruct (IHCEV1\_1 st2 STEQV) as [st2' [P1 EQV1]].
    destruct (IHCEV1_2 st2' EQV1) as [st2'' [P2 EQV2]].
    \exists st2". split.
      apply E_WhileLoop with st2'. rewrite \leftarrow H. symmetry.
      apply stequiv_beval. assumption. assumption. assumption.
      assumption.
Qed.
```

Now we need to redefine cequiv to use \neg instead of =. It is not completely trivial to do this in a way that keeps the definition simple and symmetric, but here is one approach (thanks to Andrew McCreight). We first define a looser variant of || that "folds in" the notion of equivalence.

```
Reserved Notation "c1 '/' st '||" st'" (at level 40, st at level 39). Inductive ceval': com \rightarrow state \rightarrow Prop := |E_equiv: \forall c st st' st'', c / st || st' \rightarrow st' \neg st'' \rightarrow c / st || st'' ot || st'' ot || st'' where "c1 '/' st '||" st'" := (ceval' c1 st st'). Now the revised definition of <math>cequiv' looks familiar:
```

Definition cequiv $(c1 \ c2 : \mathbf{com}) : \mathsf{Prop} :=$

```
\forall (st \ st' : \mathsf{state}),
(c1 / st | | ' st') \leftrightarrow (c2 / st | | ' st').
```

A sanity check shows that the original notion of command equivalence is at least as strong as this new one. (The converse is not true, naturally.)

```
Lemma cequiv_cequiv': \forall (c1 \ c2: \mathbf{com}),
  cequiv c1 c2 \rightarrow cequiv c1 c2.
Proof.
  unfold cequiv, cequiv'; split; intros.
     inversion H\theta; subst. apply E_equiv with st'\theta.
    apply (H \ st \ st'\theta); assumption. assumption.
     inversion H\theta; subst. apply E_equiv with st'\theta.
    apply (H \ st \ st'0). assumption. assumption.
Qed.
Exercise: 2 stars, optional (identity_assignment') Finally, here is our example once
more... (You can complete the proof.)
Example identity_assignment':
  cequiv' SKIP (X ::= Ald X).
Proof.
    unfold cequiv'. intros. split; intros.
     Case "->".
       inversion H; subst; clear H. inversion H\theta; subst.
```

apply E_equiv with (update $st'\theta \times (st'\theta \times)$).

unfold stequiv. intros. apply update_same.

Case "<-".

Admitted.

On the whole, this explicit equivalence approach is considerably harder to work with than relying on functional extensionality. (Coq does have an advanced mechanism called "setoids" that makes working with equivalences somewhat easier, by allowing them to be registered with the system so that standard rewriting tactics work for them almost as well as for equalities.) But it is worth knowing about, because it applies even in situations where

constructor. reflexivity. apply stequiv_trans with st'0.

14.8 Additional Exercises

reflexivity. assumption.

Exercise: 4 stars, optional (for_while_equiv) This exercise extends the optional add_for_loop exercise from Imp.v, where you were asked to extend the language of com-

the equivalence in question is *not* over functions. For example, if we chose to represent state mappings as binary search trees, we would need to use an explicit equivalence of this kind.

```
mands with C-style for loops. Prove that the command: for (c1; b; c2) { c3 } is equivalent to: c1; WHILE b DO c3; c2 END \Box

Exercise: 3 stars, optional (swap_noninterfering_assignments) Theorem swap_noninterfering_assignments)

\forall l1 \ l2 \ a1 \ a2, \\ l1 \neq l2 \rightarrow \\ \text{var_not_used_in_aexp} \ l1 \ a2 \rightarrow \\ \text{var_not_used_in_aexp} \ l2 \ a1 \rightarrow \\ \text{cequiv} \\ (l1 ::= a1; l2 ::= a2) \\ (l2 ::= a2; l1 ::= a1).

Proof.
```

Admitted.

Chapter 15

Library Hoare

15.1 Hoare: Hoare Logic

Require Export Imp.

In the past couple of chapters, we've begun applying the mathematical tools developed in the first part of the course to studying the theory of a small programming language, Imp.

- We defined a type of abstract syntax trees for Imp, together with an evaluation relation (a partial function on states) that specifies the operational semantics of programs.

 The language we defined, though small, captures some of the key features of full-blown languages like C, C++, and Java, including the fundamental notion of mutable state and some common control structures.
- We proved a number of *metatheoretic properties* "meta" in the sense that they are properties of the language as a whole, rather than properties of particular programs in the language. These included:
 - determinism of evaluation
 - equivalence of some different ways of writing down the definitions (e.g. functional and relational definitions of arithmetic expression evaluation)
 - guaranteed termination of certain classes of programs
 - correctness (in the sense of preserving meaning) of a number of useful program transformations
 - behavioral equivalence of programs (in the optional chapter Equiv).

If we stopped here, we would still have something useful: a set of tools for defining and discussing programming languages and language features that are mathematically precise, flexible, and easy to work with, applied to a set of key properties. All of these properties are things that language designers, compiler writers, and users might care about knowing. Indeed, many of them are so fundamental to our understanding of the programming languages we deal with that we might not consciously recognize them as "theorems." But properties that seem intuitively obvious can sometimes be quite subtle – or, in some cases, actually even wrong!

We'll return to this theme later in the course when we discuss types and type soundness.

• We saw a couple of examples of program verification – using the precise definition of Imp to prove formally that certain particular programs (e.g., factorial and slow subtraction) satisfied particular specifications of their behavior.

In this chapter, we'll take this last idea further. We'll develop a reasoning system called Floyd-Hoare Logic – commonly shortened to just Hoare Logic – in which each of the syntactic constructs of Imp is equipped with a single, generic "proof rule" that can be used to reason about programs involving this construct.

Hoare Logic originates in the 1960s, and it continues to be the subject of intensive research right up to the present day. It lies at the core of a huge variety of tools that are now being used to specify and verify real software systems.

15.2 Hoare Logic

Hoare Logic combines two beautiful ideas: a natural way of writing down *specifications* of programs, and a *compositional proof technique* for proving that these specifications are met — where by "compositional" we mean that the structure of proofs directly mirrors the structure of the programs that they are about.

15.2.1 Assertions

If we're going to talk about specifications of programs, the first thing we'll want is a way of making assertions about properties that hold at particular points during a program's execution – i.e., properties that may or may not be true of a given state of the memory.

Definition Assertion := state \rightarrow Prop.

Exercise: 1 star (assertions) Paraphrase the following assertions in English. 1) fun st => st X = 3 2) fun st => st X = x 3) fun st => st X <= st Y 4) fun st => st X = 3 \/ st X <= st Y 5) fun st => st Z * st Z <= x $/\setminus$ ~ (((S (st Z)) * (S (st Z))) <= x) 6) fun st => True 7) fun st => False

This way of writing assertions is formally correct – it precisely captures what we mean, and it is exactly what we will use in Coq proofs. We'll also want a lighter, less formal notation for discussing examples, since this one is a bit heavy: (1) every single assertion that we ever write is going to begin with $fun st \Rightarrow$; and (2) this state st is the only one that we ever use

to look up variables (we will never need to talk about two different memory states at the same time). So, when writing down assertions informally, we'll make some simplifications: drop the initial fun $st \Rightarrow$, and write just X instead of st X. Informally, instead of writing fun st => (st Z) * (st Z) <= x /\ ~ ((S (st Z)) * (S (st Z)) <= x) we'll write just Z * Z <= x /\ ~ ((S Z) * (S Z) <= x).

15.2.2 Hoare Triples

Next, we need a way of specifying – making claims about – the behavior of commands.

Since we've defined assertions as a way of making claims about the properties of states, and since the behavior of a command is to transform one state to another, it is natural to express claims about commands in the following way:

• "If command c is started in a state satisfying assertion P, and if c eventually terminates, then the final state is guaranteed to satisfy the assertion Q."

Such a claim is called a *Hoare Triple*. The property P is called the *precondition* of c, while Q is the *postcondition* of c.

```
Definition hoare_triple (P: Assertion) (c: com) (Q: Assertion) : Prop := \forall st \ st', c \ / \ st \ | \ | \ st' \rightarrow P \ st \rightarrow Q \ st'.
```

Since we'll be working a lot with Hoare triples, it's useful to have a compact notation: 1 c 2 . (Traditionally, Hoare triples are written $\{P\}$ c $\{Q\}$, but single braces are already used for other things in Coq.)

```
Notation "\{\{P\}\}\ c \{\{Q\}\}\}" := (hoare_triple P \ c \ Q)
(at level 90, \ c at next level)
: hoare\_spec\_scope.
```

Open Scope hoare_spec_scope.

(The hoare_spec_scope annotation here tells Coq that this notation is not global but is intended to be used in particular contexts. The Open Scope tells Coq that this file is one such context. The first notation – with missing postcondition – will not actually be used for a while; it's just a placeholder for a notation that we'll want to define later, when we discuss decorated programs.)

Exercise: 1 star (triples) Paraphrase the following Hoare triples in English. 1) ³ c ⁴

```
<sup>1</sup>p
<sup>2</sup>Q
<sup>3</sup>True
<sup>4</sup>X=5
```

```
2) <sup>5</sup> c <sup>6</sup>
3) <sup>7</sup> c <sup>8</sup>
4) <sup>9</sup> c <sup>10</sup>
5) <sup>11</sup> c <sup>12</sup>
```

6) 13 c 14 \square

Exercise: 1 star (valid_triples) Which of the following Hoare triples are valid – i.e., the claimed relation between P, c, and Q is true? 1) ¹⁵ X ::= 5 ¹⁶

```
2) ^{17} X ::= X + 1 ^{18}

3) ^{19} X ::= 5; Y ::= 0 ^{20}

4) ^{21} X ::= 5 ^{22}

5) ^{23} SKIP ^{24}

6) ^{25} SKIP ^{26}

7) ^{27} WHILE True DO SKIP END ^{28}

8) ^{29} WHILE X == 0 DO X ::= X + 1 END ^{30}

9) ^{31} WHILE X <> 0 DO X ::= X + 1 END ^{32}
```

(Note that we're using informal mathematical notations for expressions inside of commands, for readability. We'll continue doing so throughout the chapter.)

To get us warmed up, here are two simple facts about Hoare triples.

```
^{5}X=x
 ^{6}X=x+5)
 ^{7}X \le Y
 8Y \le X
 <sup>9</sup>True
^{10} {\sf False}
^{11}X=x
12Y=real_factx
^{14}(Z*Z) <= x/^{(((SZ)*(SZ))} <= x)
^{15} {\tt True}
^{16}X=5
^{17}X=2
^{18}X=3
^{19} {\tt True}
<sup>20</sup>X=5
^{21}X=2/\times3
<sup>22</sup>X=0
^{23} {\tt True}
^{24}{\tt False}
^{25} {\tt False}
^{26} {\tt True}
^{27} {\tt True}
^{28} {\tt False}
^{29}X=0
^{30}X=1
^{31}X=1
^{32}X=100
```

15.2.3 Weakest Preconditions

Some Hoare triples are more interesting than others. For example, ³³ X ::= Y + 1 ³⁴ is *not* very interesting: it is perfectly valid, but it tells us nothing useful. Since the precondition isn't satisfied by any state, it doesn't describe any situations where we can use the command X ::= Y + 1 to achieve the postcondition $X \leq 5$.

By contrast, 35 X ::= Y + 1 36 is useful: it tells us that, if we can somehow create a situation in which we know that $Y \le 4 \land Z = 0$, then running this command will produce a state satisfying the postcondition. However, this triple is still not as useful as it could be, because the Z = 0 clause in the precondition actually has nothing to do with the postcondition $X \le 5$. The *most* useful triple (for a given command and postcondition) is this one: 37 X ::= Y + 1 38 In other words, $Y \le 4$ is the *weakest* valid precondition of the command X ::= Y + 1 for the postcondition $X \le 5$.

In general, we say that "P is the weakest precondition of command c for postcondition Q" if

- $\{\{P\}\}\ c\ \{\{Q\}\}\$, and
- whenever P' is an assertion such that $\{\{P'\}\}\ c\ \{\{Q\}\}\}$, we have P' st implies P st for all states st.

```
^{33}False

^{34}X<=5

^{35}Y<=4/\Z=0

^{36}X<=5

^{37}Y<=4

^{38}X<=5
```

That is, P is the weakest precondition of c for Q if (a) P is a precondition for Q and c, and (b) P is the weakest (easiest to satisfy) assertion that guarantees Q after executing c.

The second of the conditions above is essentially a form of logical implication at the level of assertions. Because of the frequency of its occurrence, it is useful to define a little notation:

```
Definition assert_implies (P\ Q: Assertion): Prop:= \ \forall\ st,\ P\ st \to Q\ st. We will write P\ \tilde{\ }^{\sim}>Q (in ASCII, P\ \tilde{\ }^{\sim}>Q) for assert\_implies\ P\ Q. Notation "P\ \tilde{\ }^{\sim}>Q" := (assert_implies P\ Q) (at level 80). Notation "P\ \tilde{\ }^{\sim}>Q" := (P\ \tilde{\ }^{\sim}>Q\ \wedge\ Q\ \tilde{\ }^{\sim}>P) (at level 80).
```

Exercise: 1 star (wp) What are the weakest preconditions of the following commands for the following postconditions? 1) ³⁹ SKIP ⁴⁰

- 2) 41 X ::= Y + Z 42
- 3) 43 X ::= Y 44
- 4) ⁴⁵ IFB X == 0 THEN Y := Z + 1 ELSE Y := W + 2 FI ⁴⁶
- 5) 47 X ::= 5 48
- 6) ⁴⁹ WHILE True DO X ::= 0 END ⁵⁰ \square

Exercise: 3 stars, optional (is_wp_formal) Weakest preconditions can be defined formally as follows:

```
Definition is_wp P c Q := \{\{P\}\}\ c \{\{Q\}\}\ \land \forall P', \{\{P'\}\}\ c \{\{Q\}\}\ \rightarrow (\forall st, P' st \rightarrow P st).
```

Prove formally using the definition of hoare_triple that $Y \leq 4$ is indeed the weakest precondition of X ::= Y + 1 with respect to postcondition $X \leq 5$.

```
Theorem is_wp_example:
```

```
is_wp (fun st \Rightarrow st \ Y \le 4)
(X ::= APlus (Ald Y) (ANum 1)) (fun st \Rightarrow st \ X \le 5).
Proof.
```

```
39?
40 X=5
41?
42 X=5
43?
44 X=Y
45?
46 Y=5
47?
48 X=0
49?
50 X=0
```

15.2.4 Proof Rules

The goal of Hoare logic is to provide a *compositional* method for proving the validity of Hoare triples. That is, the structure of a program's correctness proof should mirror the structure of the program itself. To this end, in the sections below, we'll introduce one rule for reasoning about each of the different syntactic forms of commands in Imp – one for assignment, one for sequencing, one for conditionals, etc. – plus a couple of "structural" rules that are useful for gluing things together. We will prove programs correct using these proof rules, without ever unfolding the definition of *hoare_triple*.

Assignment

The rule for assignment is the most fundamental of the Hoare logic proof rules. Here's how it works.

Consider this (valid) Hoare triple: 51 X ::= Y 52 In English: if we start out in a state where the value of Y is 1 and we assign Y to X, then we'll finish in a state where X is 1. That is, the property of being equal to 1 gets transferred from Y to X.

Similarly, in 53 X ::= Y + Z 54 the same property (being equal to one) gets transferred to X from the expression Y + Z on the right-hand side of the assignment.

More generally, if a is any arithmetic expression, then 55 X ::= a 56 is a valid Hoare triple. Even more generally, a is any arithmetic expression and Q is any property of numbers, then 57 X ::= a 58 is a valid Hoare triple.

Rephrasing this a bit gives us the general Hoare rule for assignment: 59 X ::= a 60 For example, these are valid applications of the assignment rule: 61 X ::= X + 1 62

```
^{63} X ::= ^{64} ^{65} X ::= ^{66}
```

```
\begin{array}{l} 51 \text{Y=1} \\ 52 \text{X=1} \\ 53 \text{Y+Z=1} \\ 54 \text{X=1} \\ 55 \text{a=1} \\ 56 \text{X=1} \\ 57 \text{Q(a)} \\ 58 \text{Q(X)} \\ \\ 59 \text{QwhereaissubstitutedforX} \\ 60 \text{Q} \\ 61 (\text{X}<=5) \text{whereX+1issubstitutedforXi.e.,X+1}<=5 \\ 62 \text{X}<=5 \\ 63 (\text{X=3}) \text{where3issubstitutedforXi.e.,3}=3 \\ 64 \text{X=3} \\ 65 (0<=\text{X}/\text{X}<=5) \text{where3issubstitutedforXi.e.,} (0<=3/\text{\}3<=5) \\ 66 0<=\text{X}/\text{X}<=5 \\ \end{array}
```

To formalize the rule, we begin with the notion of "substitution in an assertion":

```
Definition assn_sub X a Q: Assertion := fun (st: \mathsf{state}) \Rightarrow Q (update st X (aeval st a)).
```

We ask that Q holds for the state obtained by assigning a to X, i.e. the updated state in which X is bound to the result of evaluating a. Since we've chosen to represent assertions using Coq propositions, this is the only way we can "substitute" a variable inside an assertion.

Now the precise proof rule for assignment:

```
(hoare_asgn) ^{67} X::=a ^{68}
Theorem hoare_asgn : \forall Q X a,
  \{\{assn\_sub\ X\ a\ Q\}\}\ (X:=a)\ \{\{Q\}\}.
Proof.
  unfold hoare_triple.
  intros Q X a st st' HE HQ.
  inversion HE. subst.
  unfold assn_sub in HQ. assumption. Qed.
   Here's a first formal proof using this rule.
Example assn_sub_example:
  {{assn_sub X (ANum 3) (fun st \Rightarrow st X = 3)}}
  (X ::= (ANum 3))
  \{\{\text{fun } st \Rightarrow st \ X = 3\}\}.
Proof.
  apply hoare_asgn. Qed.
Exercise: 2 stars (hoare_asgn_examples) Translate these informal Hoare triples... <sup>69</sup>
X := X + 1^{70} X := 3^{72} ...into formal statements and use hoare_asqn to prove them.
```

Exercise: 2 stars (hoare_asgn_wrong) The assignment rule looks backward to almost everyone the first time they see it. If it still seems backward to you, it may help to think a little about alternative "forward" rules. Here is a seemingly natural one:

(hoare_asgn_wrong) 73 X ::= a 74 Give a counterexample showing that this rule is incorrect

```
67assn_subXaQ
68Q
69assn_subX(X+1)(X<=5)
70X<=5
71assn_subX3(0<=X/\X<=5)
720<=X/\X<=5
73True
74X=a
```

(informally). Hint: The rule universally quantifies over the arithmetic expression a, and your counterexample needs to exhibit an a for which the rule doesn't work.

Exercise: 3 stars, optional (hoare_asgn_fwd) However, using an auxiliary variable x to remember the original value of X we can define a Hoare rule for assignment that does, intuitively, "work forwards" rather than backwards.

(hoare_asgn_fwd) 75 X ::= a 76 (where st' = update st X x) Note that we use the original value of X to reconstruct the state st' before the assignment took place. Prove that this rule is correct (the first hypothesis is the functional extensionality axiom, which you will need at some point). Also note that this rule is more complicated than $hoare_asgn$.

```
Theorem hoare_asgn_fwd:
```

```
 (\forall \ \{X \ Y \colon \mathtt{Type}\} \ \{f \ g : X \to Y\}, \ (\forall \ (x \colon X), f \ x = g \ x) \to f = g) \to \forall \ x \ a \ Q, \\ \{\{\mathtt{fun} \ st \Rightarrow Q \ st \land st \ \mathsf{X} = x\}\} \\ \mathsf{X} : := a \\ \{\{\mathtt{fun} \ st \Rightarrow Q \ (\mathtt{update} \ st \ \mathsf{X} \ x) \land st \ \mathsf{X} = \mathtt{aeval} \ (\mathtt{update} \ st \ \mathsf{X} \ x) \ a \ \}\}. \\ \mathsf{Proof.} \\ \mathsf{intros} \ functional\_extensionality \ v \ a \ Q. \\ Admitted. \\ \square
```

Exercise: 2 stars (hoare_asgn_weakest) Show that the precondition in the rule *hoare_asgn* is in fact the weakest precondition.

```
Theorem hoare_asgn_weakest : \forall P \ X \ a \ Q, \{\{P\}\}\ (X:=a)\ \{\{Q\}\} \rightarrow P \ ^{\sim} > assn\_sub\ X \ a \ Q. Proof. Admitted.
```

Consequence

Sometimes the preconditions and postconditions we get from the Hoare rules won't quite be the ones we want in the particular situation at hand – they may be logically equivalent but have a different syntactic form that fails to unify with the goal we are trying to prove, or they actually may be logically weaker (for preconditions) or stronger (for postconditions) than what we need.

⁷⁵funst=>Qst/\stX=x
76funst=>Qst'/\stX=aevalst'a

For instance, while 77 X ::= 3 78 , follows directly from the assignment rule, 79 X ::= 3 80 . does not. This triple is also valid, but it is not an instance of $hoare_asgn$ because True and $assn_sub$ X 3 (X = 3) are not syntactically equal assertions. However, they are logically equivalent, so if one triple is valid, then the other must certainly be as well. We could capture this observation with the following rule: 81 c 82 P < $^{\sim}$ > P'

(hoare_consequence_pre_equiv) 83 c 84 Generalizing this line of thought a bit further, if we can derive $\{\{P\}\}$ c $\{\{Q\}\}\}$, it is valid to change P to P' as long as P' is strong enough to imply P, and change Q to Q' as long as Q implies Q'. This observation is captured by two Rules of Consequence. 85 c 86 P $^{\sim}$ > P'

```
(hoare_consequence_pre) ^{87} c ^{88}
    ^{89} c ^{90} Q, ^{\sim} ^{\sim} > Q
 (hoare_consequence_post) 91 c 92
    Here are the formal versions:
Theorem hoare_consequence_pre : \forall (P P' Q : Assertion) c,
   \{\{P'\}\}\ c\ \{\{Q\}\}\ \rightarrow
   P \stackrel{\sim}{\sim} P' \rightarrow
   \{\{P\}\}\ c\ \{\{Q\}\}.
Proof.
   intros P P' Q c Hhoare Himp.
   intros st st' Hc HP. apply (Hhoare st st').
   assumption. apply Himp. assumption. Qed.
Theorem hoare_consequence_post : \forall (P Q Q' : Assertion) c,
   \{\{P\}\}\ c\ \{\{Q'\}\}\} \rightarrow
   Q' \sim Q \rightarrow
   \{\{P\}\}\ c\ \{\{Q\}\}.
  77assn_subX3(X=3)
  ^{78}X=3
  ^{79} {\tt True}
  80X=3
  81p,
  82<sub>0</sub>
  83p
  84<sub>0</sub>
  85p;
  86<sub>Q</sub>
  87P
  88<sub>Q</sub>
  89<sub>P</sub>
  90<sub>Q</sub>,
  91p
  92<sub>Q</sub>
```

```
Proof.
   intros P Q Q' c Hhoare Himp.
   intros st st' Hc HP.
   apply Himp.
   apply (Hhoare\ st\ st').
   assumption. assumption. Qed.
    For example, we might use the first consequence rule like this: ^{93} = ^{94} X := 1 ^{95} Or,
formally...
Example hoare_asgn_example1 :
   \{\{\text{fun } st \Rightarrow \text{True}\}\}\ (X ::= (ANum 1)) \{\{\text{fun } st \Rightarrow st \ X = 1\}\}.
Proof.
   apply hoare_consequence_pre
     with (P' := \operatorname{assn\_sub} X (\operatorname{ANum} 1) (\operatorname{fun} st \Rightarrow st X = 1)).
   apply hoare_asgn.
   intros st H. reflexivity. Qed.
    Finally, for convenience in some proofs, we can state a "combined" rule of consequence
that allows us to vary both the precondition and the postcondition. <sup>96</sup> c <sup>97</sup> P <sup>~~</sup> P' Q' <sup>~~</sup>
```

Digression: The eapply Tactic

Q

This is a good moment to introduce another convenient feature of Coq. We had to write "with (P' := ...)" explicitly in the proof of $hoare_asgn_example1$ above, to make sure that

```
93True

941=1

95X=1

96p,

97Q,

98p

99Q
```

all of the metavariables in the premises to the $hoare_consequence_pre$ rule would be set to specific values; since P' doesn't appear in the conclusion of $hoare_consequence_pre$, the process of unifying the conclusion with the current goal doesn't constrain P' to a specific assertion.

This is a little annoying, both because the assertion is a bit long and also because the very next thing we are going to do – applying the *hoare_asgn* rule – will tell us exactly what it should be! We can use eapply instead of apply to tell Coq, essentially, "Be patient: The missing part is going to be filled in soon."

```
Example hoare_asgn_example1':  \{\{\text{fun } st \Rightarrow \textbf{True}\}\}   (\mathsf{X}:=(\mathsf{ANum 1}))   \{\{\text{fun } st \Rightarrow st \ \mathsf{X}=1\}\}.  Proof.  \text{eapply hoare\_consequence\_pre.}   \text{apply hoare\_asgn.}   \text{intros } st \ H. \ \text{reflexivity. Qed.}
```

In general, eapply H tactic works just like apply H except that, instead of failing if unifying the goal with the conclusion of H does not determine how to instantiate all of the variables appearing in the premises of H, eapply H will replace these variables with existential variables (written ?nnn) as placeholders for expressions that will be determined (by further unification) later in the proof.

In order for Qed to succeed, all existential variables need to be determined by the end of the proof. Otherwise Coq will (rightfully) refuse to accept the proof. Remember that the Coq tactics build proof objects, and proof objects containing existential variables are not complete.

```
\begin{array}{l} \text{Lemma silly1}: \ \forall \ (P: \mathbf{nat} \to \mathbf{nat} \to \mathtt{Prop}) \ (Q: \mathbf{nat} \to \mathtt{Prop}), \\ (\forall \ x \ y: \mathbf{nat}, \ P \ x \ y) \to \\ (\forall \ x \ y: \mathbf{nat}, \ P \ x \ y \to Q \ x) \to \\ Q \ 42. \\ \\ \text{Proof.} \\ \text{intros} \ P \ Q \ HP \ HQ. \ \texttt{eapply} \ HQ. \ \texttt{apply} \ HP. \ Admitted. \end{array}
```

Coq gives a warning after apply HP: No more subgoals but non-instantiated existential variables: Existential $1 = ?171 : P : nat \rightarrow nat \rightarrow \text{Prop } Q : nat \rightarrow \text{Prop } HP : \forall x y : nat, P x y HQ : \forall x y : nat, P x y \rightarrow Q x \vdash nat$ Trying to finish the proof with Qed instead of Admitted gives an error:

```
Error: Attempt to save a proof with existential variables still non-instantiated
```

An additional constraint is that existential variables cannot be instantiated with terms containing (normal) variables that did not exist at the time the existential variable was created.

```
 \begin{array}{l} \text{Lemma silly2}: \ \forall \ (P: \mathbf{nat} \to \mathbf{nat} \to \mathtt{Prop}) \ (Q: \mathbf{nat} \to \mathtt{Prop}), \\ (\exists \ y, \ P \ 42 \ y) \to \\ (\forall \ x \ y: \mathbf{nat}, \ P \ x \ y \to Q \ x) \to \\ Q \ 42. \end{array}   \begin{array}{l} \mathsf{Proof}. \end{array}
```

intros P Q HP HQ. eapply HQ. destruct HP as $[y \ HP']$. Admitted.

Doing apply HP' above fails with the following error: Error: Impossible to unify "?175" with "y". In this case there is an easy fix: doing destruct HP before doing eapply HQ.

```
Lemma silly2_fixed : \forall (P: \mathbf{nat} \to \mathbf{nat} \to \mathsf{Prop}) (Q: \mathbf{nat} \to \mathsf{Prop}), (\exists \ y, \ P \ 42 \ y) \to (\forall \ x \ y: \mathbf{nat}, \ P \ x \ y \to Q \ x) \to Q \ 42.
Proof.

intros P \ Q \ HP \ HQ. destruct HP as [y \ HP']. eapply HQ. apply HP'.
```

In the last step we did apply HP' which unifies the existential variable in the goal with the variable y. The assumption tactic doesn't work in this case, since it cannot handle existential variables. However, Coq also provides an eassumption tactic that solves the goal if one of the premises matches the goal up to instantiations of existential variables. We can use it instead of apply HP'.

```
 \begin{array}{l} \text{Lemma silly2\_eassumption}: \ \forall \ (P: \textbf{nat} \rightarrow \textbf{nat} \rightarrow \texttt{Prop}) \ (Q: \textbf{nat} \rightarrow \texttt{Prop}), \\ (\exists \ y, \ P \ 42 \ y) \rightarrow \\ (\forall \ x \ y: \textbf{nat}, \ P \ x \ y \rightarrow Q \ x) \rightarrow \\ Q \ 42. \\ \text{Proof.} \\ \text{intros} \ P \ Q \ HP \ HQ. \ \text{destruct} \ HP \ \text{as} \ [y \ HP']. \ \text{eapply} \ HQ. \ eassumption. \\ \text{Qed.} \\ \end{array}
```

Exercise: 2 stars (hoare_asgn_examples_2) Translate these informal Hoare triples... 100 X ::= X + 1 101 102 X ::= 3 103 ...into formal statements and use *hoare_asgn* and *hoare_consequence_pre* to prove them.

Skip

Qed.

Since SKIP doesn't change the state, it preserves any property P:

```
100X+1<=5
101X<=5
1020<=3/3<=5
1030<=X/X<=5
```

```
(hoare_skip) ^{104} SKIP ^{105} Theorem hoare_skip : \forall P, \{\{P\}\} SKIP \{\{P\}\}. Proof. intros P st st H HP. inversion H. subst. assumption. Qed.
```

Sequencing

More interestingly, if the command c1 takes any state where P holds to a state where Q holds, and if c2 takes any state where Q holds to one where R holds, then doing c1 followed by c2 will take any state where P holds to one where R holds: 106 c1 107 108 c2 109

```
\begin{array}{c} \hline & \text{(hoare\_seq)} \ ^{110} \ \text{c1;c2} \ ^{111} \\ \hline & \text{Theorem hoare\_seq:} \ \forall \ P \ Q \ R \ c1 \ c2, \\ & \quad \{\{Q\}\} \ c2 \ \{\{R\}\} \ \rightarrow \\ & \quad \{\{P\}\} \ c1 \ \{\{Q\}\} \ \rightarrow \\ & \quad \{\{P\}\} \ c1 \ ; c2 \ \{\{R\}\} \}. \\ \hline & \text{Proof.} \\ & \text{intros} \ P \ Q \ R \ c1 \ c2 \ H1 \ H2 \ st \ st' \ H12 \ Pre. \\ & \text{inversion} \ H12; \ \text{subst.} \\ & \text{apply} \ (H1 \ st'0 \ st'); \ \text{try assumption.} \\ & \text{apply} \ (H2 \ st \ st'0); \ \text{assumption.} \ \text{Qed.} \\ \hline \end{array}
```

Note that, in the formal rule $hoare_seq$, the premises are given in "backwards" order (c2 before c1). This matches the natural flow of information in many of the situations where we'll use the rule: the natural way to construct a Hoare-logic proof is to begin at the end of the program (with the final postcondition) and push postconditions backwards through commands until we reach the beginning.

Informally, a nice way of recording a proof using the sequencing rule is as a "decorated program" where the intermediate assertion Q is written between c1 and c2: 112 X ::= a; 113 <—- decoration for Q SKIP 114

Example hoare_asgn_example3 : $\forall a n$,

```
104p

105p

106p

107Q

108Q

109R

110p

111R

112a=n

113X=n

114X=n
```

```
{{fun st ⇒ aeval st a = n}}
(X ::= a; SKIP)
{{fun st ⇒ st X = n}}.

Proof.
intros a n. eapply hoare_seq.
Case "right part of seq".
   apply hoare_skip.
Case "left part of seq".
   eapply hoare_consequence_pre. apply hoare_asgn.
   intros st H. subst. reflexivity. Qed.
```

You will most often use *hoare_seq* and *hoare_consequence_pre* in conjunction with the eapply tactic, as done above.

Exercise: 2 stars (hoare_asgn_example4) Translate this decorated program into a formal proof: $^{115} => ^{116}$ X ::= 1; $^{117} => ^{118}$ Y ::= 2 119

```
Example hoare_asgn_example4:
```

```
{{fun st \Rightarrow True}} (X ::= (ANum 1); Y ::= (ANum 2)) {{fun st \Rightarrow st \ X = 1 \land st \ Y = 2}}.

Proof.

Admitted.
```

Exercise: 3 stars (swap_exercise) Write an Imp program c that swaps the values of X and Y and show (in Coq) that it satisfies the following specification: c 121

Exercise: 3 stars, optional (hoarestate1) Explain why the following proposition can't be proven: forall (a : aexp) (n : nat), 122 (X ::= (ANum 3); Y ::= a) 123 .

Conditionals

What sort of rule do we want for reasoning about conditional commands? Certainly, if the same assertion Q holds after executing either branch, then it holds after the whole

```
115 True

116 1=1

117 X=1

118 X=1/\2=2

119 X=1/\Y=2

120 X<=Y

121 Y<=X

122 funst=>aevalsta=n

123 funst=>stY=n
```

 128 IFB b THEN c1 ELSE c2 129 However, this is rather weak. For example, using this rule, we cannot show that: 130 IFB X == 0 THEN Y ::= 2 ELSE Y ::= X + 1 FI 131 since the rule tells us nothing about the state in which the assignments take place in the "then" and "else" branches.

But, actually, we can say something more precise. In the "then" branch, we know that the boolean expression b evaluates to true, and in the "else" branch, we know it evaluates to false. Making this information available in the premises of the rule gives us more information to work with when reasoning about the behavior of c1 and c2 (i.e., the reasons why they establish the postcondition Q). ¹³² c1 ¹³³ ¹³⁴ c2 ¹³⁵

```
(hoare_if) ^{136} IFB b THEN c1 ELSE c2 FI ^{137}
```

To interpret this rule formally, we need to do a little work.

Strictly speaking, the assertion we've written, $P \wedge b$, is the conjunction of an assertion and a boolean expression, which doesn't typecheck. To fix this, we need a way of formally "lifting" any bexp b to an assertion. We'll write $bassn\ b$ for the assertion "the boolean expression b evaluates to true (in the given state)."

```
Definition bassn b: Assertion :=
   fun st \Rightarrow (beval st b = true).
    A couple of useful facts about bassn:
Lemma bexp_eval_true : \forall b st,
   beval st b = true \rightarrow (bassn b) st.
Proof.
   intros b st Hbe.
   unfold bassn. assumption. Qed.
Lemma bexp_eval_false : \forall b st,
   beval st b = false \rightarrow \neg ((bassn b) st).
Proof.
 124p
 125<sub>0</sub>
 126p
 127<sub>0</sub>
 128_{\clip}
 ^{130} {\tt True}
 <sup>131</sup>X<=Y
 132P/\b
 133<sub>Q</sub>
 134p/\~b
 136<sub>p</sub>
 137<sub>Q</sub>
```

```
intros b st Hbe contra.
  unfold bassn in contra.
  rewrite \rightarrow contra in Hbe. inversion Hbe. Qed.
   Now we can formalize the Hoare proof rule for conditionals and prove it correct.
Theorem hoare_if : \forall P \ Q \ b \ c1 \ c2,
  \{\{\text{fun } st \Rightarrow P \ st \land \text{bassn } b \ st\}\}\ c1\ \{\{Q\}\}\} \rightarrow
  \{\{\text{fun } st \Rightarrow P \ st \land \text{``(bassn } b \ st)\}\}\ c2\ \{\{Q\}\}\ \rightarrow
  \{\{P\}\}\ (IFB b THEN c1 ELSE c2 FI) \{\{Q\}\}.
Proof.
  intros P Q b c1 c2 HTrue HFalse st st' HE HP.
  inversion HE; subst.
  Case "b is true".
     apply (HTrue\ st\ st').
       assumption.
       split. assumption.
                apply bexp_eval_true. assumption.
  Case "b is false".
     apply (HFalse\ st\ st').
       assumption.
       split. assumption.
                apply bexp_eval_false. assumption. Qed.
   Here is a formal proof that the program we used to motivate the rule satisfies the speci-
fication we gave.
Example if_example:
     \{\{\text{fun } st \Rightarrow \mathsf{True}\}\}
  IFB (BEq (Ald X) (ANum 0))
     THEN (Y := (ANum 2))
     ELSE (Y := APlus (Ald X) (ANum 1))
  FΙ
     \{\{\text{fun } st \Rightarrow st \ \mathsf{X} \leq st \ \mathsf{Y}\}\}.
Proof.
  apply hoare_if.
  Case "Then".
     eapply hoare_consequence_pre. apply hoare_asgn.
     unfold bassn, assn_sub, update, assert_implies. simpl. intros st [H].
     symmetry in H; apply beq_nat_eq in H.
     rewrite H. omega.
  Case "Else".
     eapply hoare_consequence_pre. apply hoare_asgn.
     unfold assn_sub, update, assert_implies; simpl; intros st _. omega.
Qed.
```

Exercise: One-sided conditionals

Exercise: 4 stars, recommended (if1_hoare) In this exercise we consider extending Imp with "one-sided conditionals" of the form $IF1\ b\ THEN\ c\ FI$. Here b is a boolean expression, and c is a command. If b evaluates to true, then command c is evaluated. If b evaluates to false, then $IF1\ b\ THEN\ c\ FI$ does nothing.

We recommend that you do this exercise before the ones that follow, as it should help solidify your understanding of the material.

We first extend the syntax of commands, and introduce the usual notations. We use a separate module to prevent polluting the global name space.

Module IF1.

```
Inductive com : Type :=
    CSkip : com
    CAss : id \rightarrow aexp \rightarrow com
    \mathsf{CSeq}: \mathsf{com} \to \mathsf{com} \to \mathsf{com}
    Clf : bexp \rightarrow com \rightarrow com \rightarrow com
    CWhile : bexp \rightarrow com \rightarrow com
   \mid \mathsf{Clf1} : \mathsf{bexp} 	o \mathsf{com} 	o \mathsf{com}.
Tactic Notation "com_cases" tactic(first) ident(c) :=
  first;

   | E_{\text{-}}WhileLoop : \forall (st \ st' \ st'' : \text{state}) (b1 : \text{bexp}) (c1 : \text{com}),
                            beval st b1 = true \rightarrow
                            c1 / st \mid \mid st' \rightarrow
                            (WHILE b1 DO c1 END) / st' | | st'' \rightarrow
                            (WHILE b1 DO c1 END) / st \mid \mid st"
   where "c1 '/' st '||' st'" := (ceval c1 \ st \ st').
Tactic Notation "ceval_cases" tactic(first) ident(c) :=
   first;
    Case_aux c "E_Skip" | Case_aux c "E_Ass" | Case_aux c "E_Seq"
    Case_aux c "E_IfTrue" | Case_aux c "E_IfFalse"
   | Case_aux c "E_WhileEnd" | Case_aux c "E_WhileLoop"
  ].
    We repeat the definition and notation of Hoare triples.
Definition hoare_triple (P:Assertion) (c:com) (Q:Assertion) : Prop :=
   \forall st st',
           c / st \mid \mid st' \rightarrow
           P \ st \rightarrow
           Q st'.
Notation "\{\{P\}\}\ c \{\{Q\}\}\}" := (hoare_triple P \ c \ Q)
                                                     (at level 90, c at next level)
                                                     : hoare\_spec\_scope.
```

Now state and prove a theorem, *hoare_if1*, that expresses an appropriate Hoare logic proof rule for one-sided conditionals. Try to come up with a rule that is both sound and as precise as possible.

For full credit, prove formally that your rule is precise enough to show the following valid

```
Hoare triple: ^{138} IF1 Y <> 0 THEN X ::= X + Y FI ^{139}
```

Hint: Your proof of this triple may need to use the other proof rules also. Because we're working in a separate module, you'll need to copy here the rules you find necessary.

```
Lemma hoare_if1_good :  \{ \{ \text{ fun } st \Rightarrow st \ \mathsf{X} + st \ \mathsf{Y} = st \ \mathsf{Z} \ \} \}  IF1 BNot (BEq (Ald Y) (ANum 0)) THEN  \mathsf{X} ::= \mathsf{APlus} \ (\mathsf{Ald} \ \mathsf{X}) \ (\mathsf{Ald} \ \mathsf{Y})  FI  \{ \{ \text{ fun } st \Rightarrow st \ \mathsf{X} = st \ \mathsf{Z} \ \} \}.  Proof. Admitted. End IF1.  \Box
```

Loops

Finally, we need a rule for reasoning about while loops. Suppose we have a loop WHILE b DO c END and we want to find a pre-condition P and a post-condition Q such that 140 WHILE b DO c END 141 is a valid triple.

¹⁴⁸ WHILE b DO c END ¹⁴⁹ The proposition P is called an *invariant*.

```
138 X+Y=Z

139 X=Z

140 p

141 Q

142 p

143 p

144 p

145 p/\~b

146 p

147 p

148 p

149 p/\~b
```

This is almost the rule we want, but again it can be improved a little: at the beginning of the loop body, we know not only that P holds, but also that the guard b is true in the current state. This gives us a little more information to use in reasoning about c (showing that it establishes the invariant by the time it finishes). This gives us the final version of the rule: 150 c 151

```
(hoare_while) <sup>152</sup> WHILE b DO c END <sup>153</sup>
Lemma hoare_while : \forall P \ b \ c,
  \{\{\text{fun } st \Rightarrow P \ st \land \text{bassn } b \ st\}\}\ c \ \{\{P\}\}\} \rightarrow
  \{\{P\}\}\ WHILE b DO c END \{\{\text{fun } st \Rightarrow P \ st \land \neg \text{ (bassn } b \ st)\}\}.
  intros P b c Hhoare st st' He HP.
  remember (WHILE b DO c END) as wcom.
  ceval_cases (induction He) Case; try (inversion Heqwcom); subst.
  Case "E_WhileEnd".
     split. assumption. apply bexp_eval_false. assumption.
  Case "E_WhileLoop".
     apply IHHe2. reflexivity.
     apply (Hhoare\ st\ st'). assumption.
       split. assumption. apply bexp_eval_true. assumption. Qed.
Example while_example:
     \{\{\text{fun } st \Rightarrow st \ \mathsf{X} \leq 3\}\}
  WHILE (BLe (Ald X) (ANum 2))
  DO X ::= APlus (Ald X) (ANum 1) END
     \{\{\text{fun } st \Rightarrow st \ X = 3\}\}.
Proof.
  eapply hoare_consequence_post.
  apply hoare_while.
  eapply hoare_consequence_pre.
  apply hoare_asgn.
  unfold bassn, assn_sub, assert_implies, update. simpl.
     intros st [H1 H2]. apply ble_nat_true in H2. omega.
  unfold bassn, assert_implies. intros st [Hle Hb].
     simpl in Hb. remember (ble_nat (st X) 2) as le. destruct le.
     apply ex_falso_quodlibet. apply Hb; reflexivity.
     symmetry in Heqle. apply ble_nat_false in Heqle. omega.
Qed.
150P/\b
 151<sub>p</sub>
 152p
 ^{153}P/\~b
```

We can also use the while rule to prove the following Hoare triple, which may seem surprising at first...

```
Theorem always_loop_hoare: \forall P \ Q, \{\{P\}\} WHILE BTrue DO SKIP END \{\{Q\}\}.

Proof.

intros P \ Q.

apply hoare_consequence_pre with (P' := \text{fun } st : \text{state} \Rightarrow \text{True}).

eapply hoare_consequence_post.

apply hoare_while.

Case "Loop body preserves invariant".

apply hoare_post_true. intros st. apply |.

Case "Loop invariant and negated guard imply postcondition".

simpl. intros st \ [Hinv \ Hguard].

apply ex_falso_quodlibet. apply Hguard. reflexivity.

Case "Precondition implies invariant".

intros st \ H. constructor. Qed.
```

Actually, this result shouldn't be surprising. If we look back at the definition of *hoare_triple*, we can see that it asserts something meaningful *only* when the command terminates.

Print hoare_triple.

If the command doesn't terminate, we can prove anything we like about the post-condition. Here's a more direct proof of the same fact:

```
Theorem always_loop_hoare': \forall \ P \ Q, \{\{P\}\} WHILE BTrue DO SKIP END \{\{Q\}\}. Proof. unfold hoare_triple. intros P \ Q \ st \ st' \ contra. apply loop\_never\_stops in contra. inversion contra. Qed.
```

Hoare rules that only talk about terminating commands are often said to describe a logic of "partial" correctness. It is also possible to give Hoare rules for "total" correctness, which build in the fact that the commands terminate. However, in this course we will focus only on partial correctness.

Exercise: REPEAT

Module REPEATEXERCISE.

Exercise: 4 stars (hoare_repeat) In this exercise, we'll add a new command to our language of commands: *REPEAT c UNTIL* a *END*. You will write the evaluation rule for repeat and add a new Hoare rule to the language for programs involving it.

```
Inductive com : Type :=
```

```
\begin{array}{l} | \ \mathsf{CSkip} : \mathbf{com} \\ | \ \mathsf{CAsgn} : \mathbf{id} \to \mathbf{aexp} \to \mathbf{com} \\ | \ \mathsf{CSeq} : \mathbf{com} \to \mathbf{com} \to \mathbf{com} \\ | \ \mathsf{CIf} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com} \to \mathbf{com} \\ | \ \mathsf{CWhile} : \ \mathbf{bexp} \to \mathbf{com} \to \mathbf{com} \\ | \ \mathsf{CRepeat} : \ \mathbf{com} \to \mathbf{bexp} \to \mathbf{com}. \end{array}
```

REPEAT behaves like WHILE, except that the loop guard is checked after each execution of the body, with the loop repeating as long as the guard stays false. Because of this, the body will always execute at least once.

```
Tactic Notation "com_cases" tactic(first) ident(c) :=
  first;
   Case\_aux \ c "SKIP" | Case\_aux \ c "::=" | Case\_aux \ c ";"
   Case_aux c "IFB" | Case_aux c "WHILE" | Case_aux c "CRepeat" ].
Notation "'SKIP'" :=
  CSkip.
Notation "c1; c2" :=
  (CSeq c1 c2) (at level 80, right associativity).
Notation "X '::=' a" :=

```

Add new rules for *REPEAT* to *ceval* below. You can use the rules for *WHILE* as a guide, but remember that the body of a *REPEAT* should always execute at least once, and that the loop ends when the guard becomes true. Then update the *ceval_cases* tactic to handle these added cases.

```
Inductive ceval : state \rightarrow com \rightarrow state \rightarrow Prop := 
 | E_Skip : \forall st,
      ceval st SKIP st
 | E_Ass : \forall st a1 n X,
      aeval st a1 = n \rightarrow
      ceval st (X ::= a1) (update st X n)
 | E_Seq : \forall c1 c2 st st' st'',
      ceval st c1 st' \rightarrow
      ceval st c2 st'' \rightarrow
      ceval st (c1 ; c2) st''
 | E_IfTrue : \forall st st' b1 c1 c2,
      beval st b1 = true \rightarrow
```

```

```
admit.
```

```
{{ havoc_pre X \ Q }} HAVOC X {{ Q }}. Proof. 
 Admitted. Like in the house as an weakest exercise above show that your havour havour
```

Like in the $hoare_asgn_weakest$ exercise above, show that your $havoc_pre$ returns the weakest precondition.

```
Lemma hoare_havoc_weakest : \forall (P Q : Assertion) (X : \mathbf{id}), {{ P }} HAVOC X {{ Q }} \rightarrow P ~~> havoc_pre X Q. Proof. Admitted. End HIMP.
```

Theorem hoare_havoc : $\forall (Q : Assertion) (X : id)$,

15.3 Review of Hoare Logic

Above, we've introduced Hoare Logic as a tool to reasoning about Imp programs. In the reminder of this chapter we will explore a systematic way to use Hoare Logic to prove properties about programs. The rules of Hoare Logic are the following:

```
(hoare_asgn) ^{156} X::=a ^{157}
(hoare_skip) ^{158} SKIP ^{159}
     ^{160} c1 ^{161} ^{162} c2 ^{163}
(hoare_seq) ^{164} c1;c2 ^{165}
    166 c1 167 168 c2 169
^{156}assn_subXaQ
158p
159<mark>P</mark>
160<sub>P</sub>
161<sub>Q</sub>
162<sub>Q</sub>
^{163} {\tt R}
164_{\hbox{\scriptsize P}}
165<sub>R</sub>
^{166}\mathrm{P/b}
167<sub>Q</sub>
<sup>168</sup>P/\~b
169<sub>Q</sub>
```

```
(hoare_if) ^{170} IFB b THEN c1 ELSE c2 FI ^{171} ^{172} c ^{173} (hoare_while) ^{174} WHILE b DO c END ^{175} ^{176} c ^{177} P ^{\sim} > P' Q' ^{\sim} > Q (hoare_consequence) ^{178} c ^{179}
```

15.4 Decorated Programs

The beauty of Hoare Logic is that it is *compositional* – the structure of proofs exactly follows the structure of programs. This fact suggests that we could record the essential ideas of a proof informally (leaving out some low-level calculational details) by decorating programs with appropriate assertions around each statement. Such a *decorated program* carries with it an (informal) proof of its own correctness.

```
For example, here is a complete decorated program: 
 ^{180} => ^{181} X ::= x; ^{182} => ^{183} Z ::= z; ^{184} => ^{185} WHILE X <> 0 DO ^{186} => ^{187} Z ::= Z - 1; ^{188} X ::= X - 1 ^{189} END; ^{190} => ^{191} => ^{192} Z ::= Z + 1 ^{193}
```

Concretely, a decorated program consists of the program text interleaved with assertions. To check that a decorated program represents a valid proof, we check that each individual

```
170<sub>p</sub>
<sup>171</sup>Q
<sup>172</sup>P/\b
173p
174_{\crep{P}}
<sup>175</sup>P/\~b
176p
177<sub>Q</sub>,
178_{
m p}
<sup>179</sup>Q
^{180}\mathrm{True}
<sup>181</sup>x=x
^{182}X=x
^{183}X=x/\z=z
^{184}X=x/\Z=z
^{186}Z-X=z-x/\X<>0
^{187}(Z-1)-(X-1)=z-x
^{188}Z-(X-1)=z-x
^{189}Z-X=z-x
^{190}Z-X=z-x/^{(X<>0)}
^{192}Z+1=z-x+1
^{193}Z=z-x+1
```

command is *locally* consistent with its accompanying assertions in the following sense:

- SKIP is locally consistent if its precondition and postcondition are the same: ¹⁹⁴ SKIP ¹⁹⁵
- The sequential composition of commands c1 and c2 is locally consistent (with respect to assertions P and R) if c1 is locally consistent (with respect to P and P) and P0 and P1 is locally consistent (with respect to P2 and P3 is locally consistent (with respect to P3 and P3 is locally consistent (with respect to P3 and P3 is locally consistent (with respect to P3 and P4 is locally consistent (with respect to P3 and P4 is locally consistent (with respect to P3 and P4 is locally consistent (with respect to P4 and P5 is locally consistent (with respect to P5 and P6 is locally consistent (with respect to P6 and P7 is locally consistent (with respect to P6 and P8 is locally consistent (with respect to P6 and P8 is locally consistent (with respect to P6 and P8 is locally consistent (with respect to P6 and P8 is locally consistent (with respect to P6 and P8 is locally consistent (with respect to P8 and P9 a
- An assignment is locally consistent if its precondition is the appropriate substitution of its postcondition: 199 X ::= a 200
- A conditional is locally consistent (with respect to assertions P and Q) if the assertions at the top of its "then" and "else" branches are exactly $P \wedge b$ and $P / ^{\sim} b$ and if its "then" branch is locally consistent (with respect to $P \wedge b$ and Q) and its "else" branch is locally consistent (with respect to $P / ^{\sim} b$ and Q): ²⁰¹ IFB b THEN ²⁰² c1 ²⁰³ ELSE ²⁰⁴ c2 ²⁰⁵ FI ²⁰⁶
- A while loop is locally consistent if its postcondition is $P/\^{\sim}b$ (where P is its precondition) and if the pre- and postconditions of its body are exactly $P \wedge b$ and P: ²⁰⁷ WHILE b DO ²⁰⁸ c1 ²⁰⁹ END ²¹⁰
- A pair of assertions separated by \Rightarrow is locally consistent if the first implies the second (in all states): $^{211} => ^{212}$

This corresponds to the application of *hoare_consequence* and is the only place in a decorated program where checking if the decorations are correct is not fully mechanical and syntactic, but it involves logical and maybe arithmetic reasoning.

<sup>208</sup>P/\b
209p
<sup>210</sup>P/\~b
211p
212p,
```

15.5 Sample Hoare Logic Proofs

15.5.1 Example: Slow Subtraction

We've seen an Imp program for subtracting one number from another by repeatedly subtracting one from each number until the one being subtracted reaches zero.

Here is a full proof – presented as a decorated program – that this program meets a natural specification: (1) 213 => (2) 214 WHILE X <> 0 DO (3) 215 => (4) 216 Z ::= Z - 1; (5) 217 X ::= X - 1 (6) 218 END (7) 219 => (8) 220 The decorations were constructed as follows:

- Begin with the undecorated program (the unnumbered lines).
- Add the specification i.e., the outer precondition (1) and postcondition (8).
- Write down the invariant of the loop (6).
- Following the format dictated by the *hoare_while* rule, add the final use of the rule of consequence the assertion in line (7) and the check that (7) implies (8).
- Check that the loop invariant is an invariant of the loop body by using the assignment rule twice to push the invariant backwards from the end of the loop body to the beginning (line (5) and then line (4)), and then filling in the rule of consequence asserting that the invariant plus the fact that the loop guard is true (line (3)) implies line (4).
- Check that the invariant is established at the beginning of the loop verifying that line (2) is implied by line (1).

As in most Hoare Logic proofs, the only challenging part of this process is finding the right loop invariant. There is no foolproof procedure for this, but a helpful heuristic is to begin by assuming that the loop invariant is exactly the desired postcondition (i.e., that lines (6) and (8) are the same) and then calculating a bit to find out why this assertion is not an invariant of the loop body.

In this case, it quickly becomes clear that assertion (8) is not an invariant of the loop body because the loop body changes the variable Z, but (obviously) not the global constants x and z. So we need to generalize (8) to some statement that is equivalent to (8) when X

 $[\]begin{array}{c} 213 \text{X=x/} \text{Z=z} \\ 214 \text{Z-X=z-x} \\ 215 \text{Z-X=z-x/} \text{X$<>0$} \\ 216 (\text{Z-1}) - (\text{X-1}) = \text{z-x} \\ 217 \text{Z-} (\text{X-1}) = \text{z-x} \\ 218 \text{Z-X=z-x} \\ 219 \text{Z-X=z-x/} \text{X$<>0$} \\ 220 \text{Z=z-x} \end{array}$

is 0, since this will be the case when the loop terminates, and that "fills the gap" in some appropriate way when X is nonzero.

From this informal proof, it is now easy to read off a formal proof in terms of the Hoare rules:

```
Definition subtract_slowly : com :=
  WHILE BNot (BEq (Ald X) (ANum 0)) DO
    Z ::= AMinus (Ald Z) (ANum 1);
    X ::= AMinus (Ald X) (ANum 1)
  END.
Definition subtract_slowly_invariant x z :=
  fun st \Rightarrow \min(st Z) (st X) = \min(st Z) x.
Theorem subtract_slowly_correct : \forall x z,
  \{\{\text{fun } st \Rightarrow st \ \mathsf{X} = x \land st \ \mathsf{Z} = z\}\}
  subtract_slowly
  \{\{\text{fun } st \Rightarrow st \ \mathsf{Z} = \min z \ x\}\}.
Proof.
  intros x z. unfold subtract_slowly.
  eapply hoare_consequence with (P' := subtract\_slowly\_invariant x z).
  apply hoare_while.
  Case "Loop body preserves invariant".
     eapply hoare_seq. apply hoare_asgn.
     eapply hoare_consequence_pre. apply hoare_asgn.
    unfold subtract_slowly_invariant, assn_sub, update, bassn. simpl.
    intros st [Inv GuardTrue].

    unfold subtract_slowly_invariant.
     intros st [HX HZ]. omega.
  Case "Invariant and negated guard imply postcondition".
     intros st [Inv GuardFalse].
    unfold subtract_slowly_invariant in Inv.
    unfold bassn in GuardFalse. simpl in GuardFalse.
    SearchAbout [not true]. rewrite not_true_iff_false in GuardFalse.
    SearchAbout [negb false]. rewrite negb_false_iff in GuardFalse.
    SearchAbout [beq_nat true]. apply beq_nat_true in GuardFalse.
    omega. Qed.
```

15.5.2 Exercise: Reduce to Zero

Exercise: 2 stars (reduce_to_zero_correct) Here is a while loop that is so simple it needs no invariant: 221 WHILE X <> 0 DO 222 => 223 X ::= X - 1 224 END 225 => 226 Your job is to translate this proof to Coq. Refer to the $slow_subtraction$ example for ideas.

15.5.3 Exercise: Slow Addition

The following program adds the variable X into the variable Z by repeatedly decrementing X and incrementing Z.

```
Definition add_slowly : com :=
  WHILE BNot (BEq (Ald X) (ANum 0)) DO
  Z ::= APlus (Ald Z) (ANum 1);
  X ::= AMinus (Ald X) (ANum 1)
  END.
```

Exercise: 3 stars (add_slowly_decoration) Following the pattern of the *subtract_slowly* example above, pick a precondition and postcondition that give an appropriate specification of *add_slowly*; then (informally) decorate the program accordingly.

Exercise: 3 stars (add_slowly_formal) Now write down your specification of add_slowly formally, as a Coq Hoare_triple, and prove it valid.

```
221True
222True/\X<>0
223True
224True
225True/\X=0
226X=0
```

15.5.4 Example: Parity

Here's another, slightly trickier example. Make sure you understand the decorated program completely. You may find it instructive to start with the bare program and try to fill in the decorations yourself. Notice exactly where the condition $X \le x$ comes up.

```
^{227} => ^{228} Y ::= 0; ^{229} => ^{230} WHILE X <> 0 DO ^{231} => ^{232} Y ::= 1 - Y; ^{233} X ::= X - 1 ^{234} END ^{235} => ^{236}
```

And here is the formal version of this proof. Skim them, but you do not need to understand every detail (though the details are not actually very hard), since all the important ideas are already in the informal version.

```
Definition find_parity : com :=
  Y ::= (ANum 0);
  WHILE (BNot (BEq (Ald X) (ANum 0))) DO
     Y ::= AMinus (ANum 1) (Ald Y);
     X ::= AMinus (Ald X) (ANum 1)
  END.
Definition find_parity_invariant x :=
  fun st \Rightarrow
      st X < x \land ((st Y = 0 \land ev (x - st X)))
                          \vee (st Y = 1 \wedge ¬ev (x - st X))).
    We'll need the following lemma...
Lemma not_ev_ev_S_gen: \forall n,
  (\neg \text{ ev } n \rightarrow \text{ ev } (S n)) \land
  (\neg \text{ ev } (S n) \rightarrow \text{ ev } (S (S n))).
Proof.

```

Exercise: 3 stars (sqrt_informal) Write an informal decorated program corresponding to this formal correctness proof.

15.5.6 Exercise: Factorial

Module FACTORIAL.

```
Recall the mathematical factorial function...
```

```
Fixpoint real_fact (n:\mathsf{nat}): \mathsf{nat} := \mathsf{match}\ n \ \mathsf{with} \ | \ \mathsf{O} \Rightarrow 1 \ | \ \mathsf{S}\ n' \Rightarrow n \times (\mathsf{real\_fact}\ n') \ \mathsf{end}.
```

... and the Imp program that we wrote to calculate factorials:

```
Definition fact_body : com :=
  Y ::= AMult (Ald Y) (Ald Z);
  Z ::= AMinus (Ald Z) (ANum 1).
Definition fact_loop : com :=
  WHILE BNot (BEq (Ald Z) (ANum 0)) DO
  fact_body
  END.
```

 ${\tt Definition} \ {\sf fact_com}: \ {\bm com}:=$

```
Z ::= (Ald X);
Y ::= ANum 1;
fact_loop.
```

Exercise: 3 stars, optional (fact_informal) Decorate the fact_com program to show that it satisfies the specification given by the pre and postconditions below. As usual, feel free to elide the algebraic reasoning about arithmetic, the less-than relation, etc., that is formally required by the rule of consequence:

```
^{237} Z ::= X; Y ::= 1; WHILE Z <> 0 DO Y ::= Y * Z; Z ::= Z - 1 END ^{238} \square
```

Exercise: 4 stars, optional (fact_formal) Prove formally that fact_com satisfies this specification, using your informal proof as a guide. You may want to state the loop invariant separately (as we did in the examples).

```
Theorem fact_com_correct : \forall x, \{\{\text{fun } st \Rightarrow st \ \mathsf{X} = x\}\}\ \text{fact\_com} \{\{\text{fun } st \Rightarrow st \ \mathsf{Y} = \text{real\_fact } x\}\}. Proof.

Admitted.
```

End FACTORIAL.

15.6 Formalizing Decorated Programs (Optional)

The informal conventions for decorated programs amount to a way of displaying Hoare triples in which commands are annotated with enough embedded assertions that checking the validity of the triple is reduced to simple logical and algebraic calculations showing that some assertions imply others.

In this optional section, we show that this informal presentation style can actually be made completely formal.

15.6.1 Syntax

The first thing we need to do is to formalize a variant of the syntax of commands with embedded assertions. We call the new commands decorated commands, or dcoms.

```
| DClf : bexp \rightarrow Assertion \rightarrow dcom \rightarrow Assertion \rightarrow dcom
              \rightarrow Assertion\rightarrow dcom
    DCWhile : bexp \rightarrow Assertion \rightarrow dcom \rightarrow Assertion \rightarrow dcom
    DCPre : Assertion \rightarrow dcom \rightarrow dcom
   DCPost : dcom \rightarrow Assertion \rightarrow dcom.
Tactic Notation "dcom\_cases" tactic(first) ident(c) :=
  first:
  [ Case_aux c "Skip" | Case_aux c "Seq" | Case_aux c "Asgn"
    Case_aux c "If" | Case_aux c "While"
    Case\_aux \ c "Pre" | Case\_aux \ c "Post" |.
Notation "'SKIP' {{ P }}"
       := (\mathsf{DCSkip}\ P)
       (at level 10): dcom\_scope.
Notation "l'::=' a {{ P}}"
       := (\mathsf{DCAsgn}\ l\ a\ P)
       (at level 60, a at next level): dcom\_scope.
Notation "'WHILE' b 'DO' {{ Pbody }} d 'END' {{ Ppost }}"
       := (DCWhile \ b \ Pbody \ d \ Ppost)
       (at level 80, right associativity) : dcom\_scope.
Notation "'IFB' b 'THEN' {{ P }} d 'ELSE' {{ P' }} d' 'FI' {{ Q }}"
       := (\mathsf{DClf}\ b\ P\ d\ P'\ d'\ Q)
       (at level 80, right associativity): dcom\_scope.
Notation "'=>' {{ P }} d"
       := (\mathsf{DCPre}\ P\ d)
       (at level 90, right associativity): dcom\_scope.
Notation "\{\{P\}\}\ d"
       := (\mathsf{DCPre}\ P\ d)
       (at level 90): dcom\_scope.
Notation "d '=>' \{\{P\}\}"
       := (\mathsf{DCPost}\ d\ P)
       (at level 91, right associativity) : dcom\_scope.
Notation "d; d' "
       := (DCSeq d d')
       (at level 80, right associativity) : dcom\_scope.
Delimit Scope dcom\_scope with dcom.
```

To avoid clashing with the existing Notation definitions for ordinary com mands, we introduce these notations in a special scope called $dcom_scope$, and we wrap examples with the declaration % dcom to signal that we want the notations to be interpreted in this scope.

Careful readers will note that we've defined two notations for the DCPre constructor, one with and one without $a \Rightarrow$. The "without" version is intended to be used to supply the initial precondition at the very top of the program.

```
Example dec_while : dcom := (
   \{\{ \text{ fun } st \Rightarrow \mathsf{True } \}\}
   WHILE (BNot (BEq (Ald X) (ANum 0)))
  DO
      \{\{ \text{ fun } st \Rightarrow \text{True } \land \text{ bassn } (BNot (BEg (Ald X) (ANum 0))) \ st \} \}
      X ::= (AMinus (Ald X) (ANum 1))
      \{\{ fun \ \_ \Rightarrow True \} \}
   END
   \{\{ \text{ fun } st \Rightarrow \mathsf{True} \land \neg \mathsf{bassn} (\mathsf{BNot} (\mathsf{BEq} (\mathsf{Ald} \mathsf{X}) (\mathsf{ANum} 0))) \ st \}\} \Rightarrow
   \{\{ \text{ fun } st \Rightarrow st \ X = 0 \} \}
) \% dcom.
    It is easy to go from a dcom to a com by erasing all annotations.
Fixpoint extract (d:dcom) : com :=
   match d with
     DCSkip \_ \Rightarrow SKIP
     DCSeq d1 d2 \Rightarrow (\text{extract } d1 ; \text{ extract } d2)
     \mathsf{DCAsgn}\ X\ a\ \_ \Rightarrow X::= a
     DCIf b - d1 - d2 - \Rightarrow IFB b THEN extract d1 ELSE extract d2 FI
     DCWhile b - d \rightarrow WHILE b DO extract d END
     DCPre _{-} d \Rightarrow extract d
    DCPost d \rightarrow \text{extract } d
```

The choice of exactly where to put assertions in the definition of dcom is a bit subtle. The simplest thing to do would be to annotate every dcom with a precondition and postcondition. But this would result in very verbose programs with a lot of repeated annotations: for example, a program like SKIP;SKIP would have to be annotated as 239 (240 SKIP 241); (242 SKIP 243) 244 , with pre- and post-conditions on each SKIP, plus identical pre- and post-conditions on the semicolon!

Instead, the rule we've followed is this:

- \bullet The post-condition expected by each dcom d is embedded in d
- The pre-condition is supplied by the context.

In other words, the invariant of the representation is that a $dcom\ d$ together with a precondition P determines a Hoare triple $\{\{P\}\}\ (extract\ d)\ \{\{post\ d\}\}\$, where post is defined as follows:

```
239P
240P
241P
242P
243P
244P
```

```
Fixpoint post (d:\mathbf{dcom}): Assertion := match d with | DCSkip P\Rightarrow P | DCSeq d1 d2\Rightarrow post d2 | DCAsgn X a Q\Rightarrow Q | DCIf _- _- d1 _- d2 Q\Rightarrow Q | DCWhile b Pbody c Ppost <math>\Rightarrow Ppost | DCPre _- d\Rightarrow post d | DCPost c Q\Rightarrow Q end.
```

We can define a similar function that extracts the "initial precondition" from a decorated program.

```
Fixpoint pre (d:\mathbf{dcom}): Assertion := match d with | DCSkip P\Rightarrow fun st\Rightarrow True | DCSeq c1 c2\Rightarrow pre c1 | DCAsgn X a Q\Rightarrow fun st\Rightarrow True | DCIf _- _- t _- e _- \Rightarrow fun st\Rightarrow True | DCWhile b Pbody c Ppost <math>\Rightarrow fun st\Rightarrow True | DCPre P c \Rightarrow P | DCPost c Q\Rightarrow pre c end.
```

This function is not doing anything sophisticated like calculating a weakest precondition; it just recursively searches for an explicit annotation at the very beginning of the program, returning default answers for programs that lack an explicit precondition (like a bare assignment or SKIP).

Using *pre* and *post*, and assuming that we adopt the convention of always supplying an explicit precondition annotation at the very beginning of our decorated programs, we can express what it means for a decorated program to be correct as follows:

```
Definition dec_correct (d:dcom) := \{\{pre \ d\}\}\} (extract d) \{\{post \ d\}\}\}.
```

To check whether this Hoare triple is *valid*, we need a way to extract the "proof obligations" from a decorated program. These obligations are often called *verification conditions*, because they are the facts that must be verified to see that the decorations are logically consistent and thus add up to a complete proof of correctness.

15.6.2 Extracting Verification Conditions

The function $verification_conditions$ takes a $dcom\ d$ together with a precondition P and returns a proposition that, if it can be proved, implies that the triple $\{\{P\}\}\ (extract\ d)\ \{\{post\ d\}\}\$ is valid. It does this by walking over d and generating a big conjunction including all the

"local checks" that we listed when we described the informal rules for decorated programs. (Strictly speaking, we need to massage the informal rules a little bit to add some uses of the rule of consequence, but the correspondence should be clear.)

```
Fixpoint verification_conditions (P : Assertion) (d : dcom) : Prop :=
  match d with
   | DCSkip Q \Rightarrow
        (P \sim Q)
  | DCSeq d1 d2 \Rightarrow
        verification_conditions P d1
        \land verification_conditions (post d1) d2
  | DCAsgn X \ a \ Q \Rightarrow
        (P \sim > assn\_sub X a Q)
  | DCIf b P1 d1 P2 d2 Q \Rightarrow
        ((fun st \Rightarrow P \ st \land \mathsf{bassn} \ b \ st) ~~> P1)
        \land ((fun st \Rightarrow P \ st \land \neg (bassn b \ st)) ~~> P2)
        \land (Q = post d1) \land (Q = post d2)
        \land verification_conditions P1 d1
        \land verification_conditions P2 d2
  | DCWhile b Pbody d Ppost \Rightarrow
        (P \sim post d)
        \land (Pbody = (fun st \Rightarrow post d st \land bassn b st))
        \land (Ppost = (fun st \Rightarrow post d st \land ~(bassn b st)))
        \land verification_conditions Pbody d
  | DCPre P' d \Rightarrow
        (P \sim P') \land \text{verification\_conditions } P' d
  | DCPost d Q \Rightarrow
        verification_conditions P \ d \land (post \ d \sim Q)
  end.
```

And now, the key theorem, which captures the claim that the *verification_conditions* function does its job correctly. Not surprisingly, we need all of the Hoare Logic rules in the proof. We have used *in* variants of several tactics before to apply them to values in the context rather than the goal. An extension of this idea is the syntax *tactic* in *, which applies *tactic* in the goal and every hypothesis in the context. We most commonly use this facility in conjunction with the simpl tactic, as below.

```
Theorem verification_correct: \forall d \ P, verification_conditions P \ d \rightarrow \{\{P\}\}\} (extract d) \{\{\text{post } d\}\}\}. Proof. dcom\_cases (induction d) Case; intros P \ H; simpl in *. Case "Skip". eapply hoare_consequence_pre. apply hoare_skip.
```

```
assumption.
  Case "Seq".
    inversion H as [H1 H2]. clear H.
    eapply hoare_seq.
      apply IHd2. apply H2.
      apply IHd1. apply H1.
  Case "Asgn".
    eapply hoare_consequence_pre.
      apply hoare_asgn.
      assumption.
  Case "If".
    inversion H as [HPre1 \mid HPre2 \mid Hd1 \mid Hd2 \mid HThen \mid HElse \mid]]]]; clear H.
    subst.
    apply hoare_if.
      eapply hoare_consequence_pre. apply IHd1. eassumption. assumption.
      rewrite Hd2.
      eapply hoare_consequence_pre. apply IHd2. eassumption. assumption.
  Case "While".
    inversion H as [Hpre\ [Hbody\ [Hpost\ Hd]]]; subst; clear H.
    eapply hoare_consequence_pre.
    apply hoare_while with (P := post d).
      apply IHd. apply Hd.
      assumption.
  Case "Pre".
    inversion H as [HP \ Hd]; clear H.
    eapply hoare_consequence_pre. apply IHd. apply Hd. assumption.
  Case "Post".
    inversion H as [Hd HQ]; clear H.
    eapply hoare_consequence_post. apply IHd. apply Hd. assumption.
Qed.
```

15.6.3 Examples

The propositions generated by *verification_conditions* are fairly big, and they contain many conjuncts that are essentially trivial.

```
Eval simpl in (verification_conditions (fun st \Rightarrow True) dec_while).
```

We can certainly work with them using just the tactics we have so far, but we can make things much smoother with a bit of automation. We first define a custom *verify* tactic that applies splitting repeatedly to turn all the conjunctions into separate subgoals and then uses omega and eauto (a handy general-purpose automation tactic that we'll discuss in detail later) to deal with as many of them as possible.

```
Tactic Notation "verify" :=
```

```
apply verification_correct;
  repeat split;
  simpl; unfold assert_implies;
  unfold bassn in *; unfold beval in *; unfold aeval in *;
  unfold assn_sub; intros;
  repeat rewrite update_eq;
  repeat (rewrite update_neq; [| reflexivity]);
  repeat match goal with [H: \_ \land \_ \vdash \_] \Rightarrow \text{destruct } H \text{ end};
  repeat rewrite not_true_iff_false in *;
  repeat rewrite not_false_iff_true in *;
  repeat rewrite negb_true_iff in *;
  repeat rewrite negb_false_iff in *;
  repeat rewrite beq_nat_true_iff in *;
  repeat rewrite beq_nat_false_iff in *;
  try eauto; try omega.
    What's left after verify does its thing is "just the interesting parts" of checking that
the decorations are correct. For very simple examples verify immediately solves the goal
(provided that the annotations are correct).
Theorem dec_while_correct:
  dec_correct dec_while.
Proof. verify. Qed.
    Another example (formalizing a decorated program we've seen before):
Example subtract_slowly_dec (x:nat) (z:nat) : dcom := (
     \{\{ \text{ fun } st \Rightarrow st \ X = x \land st \ Z = z \} \}
  WHILE BNot (BEq (Ald X) (ANum 0))
  DO {{ fun st \Rightarrow st Z - st X = z - x}
                      \land bassn (BNot (BEq (Ald X) (ANum 0))) st }}
      Z ::= AMinus (Ald Z) (ANum 1)
         \{\{ \text{ fun } st \Rightarrow st \ \mathsf{Z} - (st \ \mathsf{X} - 1) = z - x \} \} ;
      X ::= AMinus (Ald X) (ANum 1)
         \{\{ \text{ fun } st \Rightarrow st \ \mathsf{Z} - st \ \mathsf{X} = z - x \} \}
  END
     \{\{ \text{ fun } st \Rightarrow st \ \mathsf{Z} \}
                      - st X
                  \land \neg  bassn (BNot (BEq (Ald X) (ANum 0))) st }}
     \{\{ \text{ fun } st \Rightarrow st \ \mathsf{Z} = z - x \} \}
) \% dcom.
Theorem subtract_slowly_dec_correct : \forall x z,
```

```
{\tt dec\_correct} (subtract_slowly_dec x z). Proof. intros x z. verify. Qed.
```

Exercise: 3 stars, optional (slow_assignment_dec) A roundabout way of assigning a number currently stored in X to the variable Y is to start Y at 0, then decrement X until it hits 0, incrementing Y at each step.

```
Here is an informal decorated program that implements this idea given a parameter x: ^{245} X ::= x ^{246} ; Y ::= 0 ^{247} ; WHILE X <> 0 DO ^{248} X ::= X - 1 ^{249} ; Y ::= Y + 1 ^{250} END ^{251}
```

Write a corresponding formal decorated program (parametrized by x) and prove it correct.

```
Example slow_assignment_dec (x:nat): dcom := admit.

Theorem slow_assignment_dec_correct: \forall x, dec_correct (slow_assignment_dec x).

Proof. Admitted.
```

Exercise: 4 stars, optional (factorial_dec) Remember the factorial function we worked with before:

```
Fixpoint real_fact (n:\mathbf{nat}): \mathbf{nat}:= match n with | \mathbf{O} \Rightarrow \mathbf{1} | \mathbf{S} \ n' \Rightarrow n \times (\mathsf{real\_fact} \ n') end.
```

Following the pattern of *subtract_slowly_dec*, write a decorated Imp program that implements the factorial function, and prove it correct.

```
Definition div_mod_dec (a \ b : nat) : dcom := (\{ fun \ st \Rightarrow True \} \} \Rightarrow \{ \{ fun \ st \Rightarrow b \times 0 + a = a \} \} \}
X ::= ANum \ a
\{ fun \ st \Rightarrow b \times 0 + st \ X = a \} \};
Y ::= ANum \ 0
245 True
246 X = X
247 X = X / Y = 0
248 X + Y = X / X > 0
249 Y + X + 1 = X
250 Y + X = X
251 Y = X / X = 0
```

```
\{\{ \text{ fun } st \Rightarrow b \times st \ Y + st \ X = a \} \};
   WHILE (BLe (ANum b) (Ald X)) DO
      \{\{ \text{ fun } st \Rightarrow b \times st \ Y + st \ X = a \land (\text{bassn } (\text{BLe } (\text{ANum } b) \ (\text{Ald } X)) \ st) \} \} \Rightarrow
      \{\{ \text{ fun } st \Rightarrow b \times (st \ Y + 1) + (st \ X - b) = a \} \}
      X ::= AMinus (Ald X) (ANum b)
      \{\{ \text{ fun } st \Rightarrow b \times (st Y + 1) + st X = a \} \};
      Y ::= APlus (Ald Y) (ANum 1)
      \{\{ \text{ fun } st \Rightarrow b \times st \ Y + st \ X = a \} \}
   END
   \{\{ \text{ fun } st \Rightarrow b \times st \ Y + st \ X = a \land \text{``(bassn (BLe (ANum b) (Ald X)) } st \} \} \Rightarrow
   \{\{ \text{ fun } st \Rightarrow b \times st \ Y + st \ X = a \land (st \ X < b) \} \}
)\% dcom.
Theorem div_mod_dec_correct : \forall a \ b,
   dec\_correct (div\_mod\_dec \ a \ b).
Proof.
   intros a b. verify.
   Case "1". apply ble_nat_true in H0. rewrite mult_plus_distr_l. omega.
   Case "2". apply ble_nat_false in H0. omega.
Qed.
```

Chapter 16

Library HoareList

16.1 HoareList: Hoare Logic with Lists

Require Export SfLib.

16.2 Imp Programs with Lists

There are only so many numeric functions with interesting properties that have simple proofs. (Of course, there are lots of interesting functions on numbers and they have many interesting properties – this is the whole field of number theory! – but proving these properties often requires developing a lot of supporting lemmas.) In order to able to write a few more programs to reason about, we introduce here an extended version of Imp where variables can range over both numbers and lists of numbers. The basic operations are extended to also include taking the head and tail of lists, and testing lists for nonemptyness.

To do this, we only need to change the definitions of *state*, *aexp*, *aeval*, *bexp*, and *beval*. The definitions of *com* and *ceval* can be reused verbatim, although we need to copy-and-paste them in the context of the new definitions.

We start by repeating some material from chapter *Imp*.

16.2.1 Repeated Definitions

```
Inductive id: Type := Id: nat \rightarrow id.

Definition beq_id id1 id2:= id2 with id2 with id2 with id2 and id3 id3 with id3 where id3 id4 id5 i
```

```
Proof.
  intros. destruct i.
  apply beq_nat_refl. Qed.
Theorem beg_id_eq : \forall i1 i2,
  true = beq_id i1 i2 \rightarrow i1 = i2.
Proof.
  intros i1 i2 H.
  destruct i1. destruct i2.
  apply beq_nat_eq in H. subst.
  reflexivity. Qed.
Theorem beq_id_false_not_eq : \forall i1 i2,
  beq_id i1 i2 = false \rightarrow i1 \neq i2.
Proof.
  intros i1 i2 H.
  destruct i1. destruct i2.
  apply beq_nat_false in H.
  intros C. apply H. inversion C. reflexivity. Qed.
Theorem not_eq_beq_id_false : \forall i1 i2,
  i1 \neq i2 \rightarrow \mathsf{beq\_id}\ i1\ i2 = \mathsf{false}.
Proof.
  intros i1 i2 H.
  destruct i1. destruct i2.
  assert (n \neq n\theta).
     intros C. subst. apply H. reflexivity.
  apply not_eq_beq_false. assumption. Qed.
Definition X : id := Id 0.
Definition Y : id := Id 1.
Definition Z : id := Id 2.
```

16.2.2 Extensions

Now we come to the key changes.

Rather than evaluating to a nat, an aexp in our new language will evaluate to a value – an element of type val – which can be either a nat or a list of nats.

Similarly, *states* will now map identifiers to *vals* rather than *nats*, so that we can store lists in mutable variables.

```
Inductive val : Type :=
| VNat : nat → val
| VList : list nat → val.

Definition state := id → val.

Definition empty_state : state := fun _ ⇒ VNat 0.
```

```
Definition update (st : state) (X:id) (v : val) : state := fun <math>X' \Rightarrow if beg_id X X' then v else st X'.
```

Imp does not have a static type system, so nothing prevents the programmer from e.g. adding two lists or taking the head of a number. We have to decide what to do in such nonsensical situations.

We adopt a simple solution: if an arithmetic function is given a list as an argument we treat the list as if it was the number 0. Similarly, if a list function is given a number as an argument we treat the number as if it was *nil*. (Cf. Javascript, where adding 3 to the empty list evaluates to 3...)

The two functions asnat and aslist interpret vals in a numeric or a list context; aeval calls these whenever it evaluates an arithmetic or a list operation.

```
Definition asnat (v: \mathbf{val}): \mathbf{nat} := \max v \text{ with } | \mathsf{VNat} \ n \Rightarrow n | \mathsf{VList} \ _ \Rightarrow 0 | \mathsf{val} end.

Definition as list (v: \mathbf{val}): \mathsf{list} \ \mathsf{nat} := \max v \text{ with } | \mathsf{VNat} \ n \Rightarrow [] | \mathsf{VList} \ \mathit{xs} \Rightarrow \mathit{xs} end.
```

Now we fill in the definitions of abstract syntax and evaluation functions for arithmetic and boolean expressions.

```
Inductive aexp: Type :=
   ANum : nat \rightarrow aexp
    Ald: id \rightarrow aexp
    APlus : aexp \rightarrow aexp \rightarrow aexp
    AMinus : aexp \rightarrow aexp \rightarrow aexp
   AMult : aexp \rightarrow aexp \rightarrow aexp
    AHead : aexp \rightarrow aexp
    ATail : aexp \rightarrow aexp
    ACons : aexp \rightarrow aexp \rightarrow aexp
    ANil: aexp.
Tactic Notation "aexp\_cases" tactic(first) ident(c) :=
  first:
  [ Case_aux c "ANum" | Case_aux c "AId" | Case_aux c "APlus"
    Case_aux c "AMinus" | Case_aux c "AMult"
    Case_aux c "AHead" | Case_aux c "ATail"
    Case\_aux \ c "ACons" | Case\_aux \ c "ANil" ].
```

```
Definition tail (l : list nat) :=
  match l with
    x::xs \Rightarrow xs
  | [] \Rightarrow []
  end.
Definition head (l : list nat) :=
  \mathtt{match}\ l with
   |x::xs\Rightarrow x
   | [] \Rightarrow 0
  end.
Fixpoint aeval (st : state) (e : aexp) : val :=
  match e with
    ANum n \Rightarrow VNat n
    Ald i \Rightarrow st i
    APlus a1 a2 \Rightarrow VNat (asnat (aeval st a1) + asnat (aeval st a2))
    AMinus a1 a2 \Rightarrow VNat (asnat (aeval st a1) – asnat (aeval st a2))
    AMult a1 a2 \Rightarrow VNat (asnat (aeval st a1) \times asnat (aeval st a2))
   | ATail a \Rightarrow VList (tail (aslist (aeval st a)))
    AHead a \Rightarrow VNat (head (aslist (aeval <math>st \ a)))
    ACons a1 a2 \Rightarrow VList (asnat (aeval st a1) :: aslist (aeval st a2))
    ANil \Rightarrow VList []
  end.
    We extend bexps with an operation to test if a list is nonempty and adapt beval acord-
ingly.
Inductive bexp: Type :=
   BTrue : bexp
    BFalse: bexp
    \mathsf{BEq}: \mathsf{aexp} \to \mathsf{aexp} \to \mathsf{bexp}
    BLe : aexp \rightarrow aexp \rightarrow bexp
    BNot : bexp \rightarrow bexp
    \mathsf{BAnd}: \mathbf{bexp} \to \mathbf{bexp} \to \mathbf{bexp}
  | BlsCons : aexp \rightarrow bexp.
Tactic Notation "bexp_cases" tactic(first) ident(c) :=
  first:
   [ Case_aux c "BTrue" | Case_aux c "BFalse" | Case_aux c "BEq"
    Case_aux c "BLe" | Case_aux c "BNot" | Case_aux c "BAnd"
   | Case\_aux \ c "BIsCons" |.
Fixpoint beval (st : state) (e : bexp) : bool :=
  match e with
```

end.

16.2.3 Repeated Definitions

Now we need to repeat a little bit of low-level work from Imp.v, plus the definitions of com and ceval. There are no interesting changes – it's just a matter of repeating the same definitions, lemmas, and proofs in the context of the new definitions of arithmetic and boolean expressions.

(Is all this cutting and pasting really necessary? No: Coq includes a powerful module system that we could use to abstract the repeated definitions with respect to the varying parts. But explaining how it works would distract us from the topic at hand.)

```
Theorem update_eq : \forall n \ V \ st,
  (update st \ V \ n) V = n.
Proof.
  intros n \ V \ st.
  unfold update.
  rewrite \leftarrow beg_id_refl.

16.3.1 Reasoning About Programs with Lists

Now let's look at a formal Hoare Logic proof for a program that works with lists. We will verify the following program, which checks if the number Y occurs in the list X, and if so sets Z to 1.

```
\label{eq:Definition list_member} \begin{split} \text{Definition list_member} &:= \\ \text{WHILE BlsCons (Ald X) DO} \\ \text{IFB (BEq (Ald Y) (AHead (Ald X))) THEN} \\ Z &:= (ANum 1) \end{split}
```

```
ELSE
               SKIP
         FI;
         X ::= ATail (Ald X)
     END.
        The informal proof looks like this: ^{25} = ^{26} WHILE (BIsCons X) DO ^{27} IFB (Y ==
head X) THEN ^{28} = ^{29} Z ::= 1 ^{30} ELSE ^{31} = ^{32} SKIP ^{33} FI; ^{34} X ::= ATail X ^{35} END ^{36}
        The only interesting part of the proof is the choice of loop invariant: exists p, p + + X =
1 / (Z = 1 < -> appears_in n p) This states that at each iteration of the loop, the original
list l is equal to the append of the current value of X and some other list p which is not the
value of any variable in the program, but keeps track of enough information from the original
state to make the proof go through. (Such a p is sometimes called a "ghost variable").
        In order to show that such a list p exists, in each iteration we add the head of X to the
end of p. This needs the function snoc, from Poly.v.
Fixpoint snoc \{X: \mathsf{Type}\}\ (l: \mathsf{list}\ X)\ (v:X): (\mathsf{list}\ X) :=
    match l with
     |\mathsf{nil}| \Rightarrow [v]
     |\cos h| t \Rightarrow h :: (\operatorname{snoc} t| v)
     end.
        The main proof uses several lemmas about snoc and ++.
Lemma snoc_equation : \forall (A : Type) (h:A) (x y : list A),
     snoc x h ++ y = x ++ h :: y.

```

Exercise: 3 stars (list_sum) Here is a direct definition of the sum of the elements of a list, and an Imp program that computes the sum.

```
Definition sum l := \mathsf{fold\_right\ plus\ }0\ l.
Definition sum\_program :=
Y ::= ANum 0;
WHILE (BlsCons (Ald X)) D0
Y ::= APlus (Ald Y) (AHead (Ald X));
X ::= ATail (Ald X)
END.
```

Provide an *informal* proof of the following specification of *sum_program* in the form of a decorated version of the program.

```
Definition sum_program_spec := \forall l, {{ fun st \Rightarrow \text{aslist } (st \ X) = l }} sum_program {{ fun <math>st \Rightarrow \text{asnat } (st \ Y) = \text{sum } l }}.
```

Exercise: 4 stars (list_reverse) Recall the function rev from Poly.v, for reversing lists.

```
Fixpoint rev \{X: \texttt{Type}\}\ (l: \texttt{list}\ X): \texttt{list}\ X := \texttt{match}\ l \ \texttt{with} |\ \texttt{nil}\ \Rightarrow\ [] |\ \texttt{cons}\ h\ t \Rightarrow \texttt{snoc}\ (\texttt{rev}\ t)\ h end.
```

Write an Imp program $list_reverse_program$ that reverses lists. Formally prove that it satisfies the following specification: forall 1: list nat, ³⁸ list_reverse_program ³⁹. You may find the lemmas $append_nil$ and $rev_equation$ useful.

```
Lemma rev_equation : \forall (A : Type) (h : A) (x y : list A), rev (h :: x) ++ y = rev x ++ h :: y.

Proof.

intros. simpl. apply snoc_equation.

\frac{^{38}X=1/\{Y=nil\}}{^{39}Y=revl}
```

Qed.

Finally, for a bigger example, let's redo the proof of *list_member_correct* from above using our new tools.

Notice that the *verify* tactic leaves subgoals for each "interesting" use of *hoare_consequence* – that is, for each \Rightarrow that occurs in the decorated program, except for the ones that can be eliminated by repeated application of a few simple automated tactics. Each of these implications relies on a fact about lists, for example that l ++ [] = l. In other words, the Hoare logic infrastructure has taken care of the boilerplate reasoning about the execution of imperative programs, while the user has to prove lemmas that are specific to the problem domain (e.g. lists or numbers).

16.4 Formal Decorated Programs

Again, the definitions are copied verbatim from Hoare.v

Chapter 17

Library HoareAsLogic

17.1 HoareAsLogic: Hoare Logic as a Logic

Require Export Hoare.

The presentation of Hoare logic in chapter *Hoare* could be described as "model-theoretic": the proof rules for each of the constructors were presented as *theorems* about the evaluation behavior of programs, and proofs of program correctness (validity of Hoare triples) were constructed by combining these theorems directly in Coq.

Another way of presenting Hoare logic is to define a completely separate proof system – a set of axioms and inference rules that talk about commands, Hoare triples, etc. – and then say that a proof of a Hoare triple is a valid derivation in *that* logic. We can do this by giving an inductive definition of *valid derivations* in this new logic.

```
Inductive hoare_proof : Assertion \rightarrow com \rightarrow Assertion \rightarrow Type :=
   \mid \mathsf{H\_Skip} : \forall P,
         hoare_proof P (SKIP) P
   \mid \mathsf{H}_{\mathsf{A}}\mathsf{sgn} : \forall \ Q \ V \ a,
         hoare_proof (assn_sub V a Q) (V ::= a) Q
   \mid \mathsf{H\_Seq} : \forall \ P \ c \ Q \ d \ R,
         hoare_proof P c Q 	o hoare_proof Q d R 	o hoare_proof P (c;d) R
   \mid \mathsf{H}_{\mathsf{L}}\mathsf{lf} : \forall P \ Q \ b \ c1 \ c2,
      \mathbf{hoare\_proof} \ (\mathtt{fun} \ st \Rightarrow P \ st \ \land \ \mathsf{bassn} \ b \ st) \ c1 \ Q \rightarrow
      hoare\_proof P (IFB b THEN c1 ELSE c2 FI) Q
   \mid \mathsf{H}_{-}\mathsf{While} : \forall P \ b \ c,
      hoare_proof (fun st \Rightarrow P \ st \land bassn \ b \ st) \ c \ P \rightarrow
      hoare_proof P (WHILE b DO c END) (fun st \Rightarrow P st \land \neg (bassn b st))
   \mid \mathsf{H}_{-}\mathsf{Consequence} : \forall (P \ Q \ P' \ Q' : \mathsf{Assertion}) \ c,
      hoare_proof P' \ c \ Q' \rightarrow
      (\forall st, P st \rightarrow P' st) \rightarrow
```

```
(\forall st, Q'st \rightarrow Qst) \rightarrow
     hoare_proof P \ c \ Q
  \mid \mathsf{H}_{\mathsf{L}}\mathsf{Consequence\_pre} : \forall (P \ Q \ P' : \mathsf{Assertion}) \ c,
     hoare_proof P' c Q \rightarrow
     (\forall st, P st \rightarrow P' st) \rightarrow
     hoare_proof P c Q
  | H_{\text{-}} Consequence_{\text{-}} post : \forall (P Q Q' : Assertion) c,
     hoare_proof P \ c \ Q' \rightarrow
     (\forall st, Q'st \rightarrow Qst) \rightarrow
     hoare_proof P \ c \ Q.
Tactic Notation "hoare_proof_cases" tactic(first) ident(c) :=
  first;
    Case_aux c "H_Skip" | Case_aux c "H_Asgn" | Case_aux c "H_Seq"
    Case_aux c "H_If" | Case_aux c "H_While" | Case_aux c "H_Consequence"
   Case_aux c "H_Consequence_pre" | Case_aux c "H_Consequence_post" |.
   For example, let's construct a proof object representing a derivation for the hoare triple
<sup>1</sup> X::=X+1; X::=X+2 <sup>2</sup>. We can use Coq's tactics to help us construct the proof object.
Example sample_proof
                : hoare_proof
                      (assn_sub X (APlus (Ald X) (ANum 1))
                        (assn_sub X (APlus (Ald X) (ANum 2))
                           (fun st \Rightarrow st X = 3))
                      (X ::= APlus (Ald X) (ANum 1); (X ::= APlus (Ald X) (ANum 2)))
                      (fun st \Rightarrow st X = 3).
Proof.
  apply H_Seq with (assn_sub X (APlus (Ald X) (ANum 2))
                           (fun st \Rightarrow st X = 3).
  apply H_Asgn. apply H_Asgn.
Qed.
Exercise: 2 stars Prove that such proof objects represent true claims.
Theorem hoare_proof_sound : \forall P \ c \ Q,
  hoare_proof P \ c \ Q \rightarrow \{\{P\}\} \ c \ \{\{Q\}\}\}.
Proof.
    Admitted.
    We can also use Coq's reasoning facilities to prove metatheorems about Hoare Logic. For
example, here are the analogs of two theorems we saw in chapter Hoare – this time expressed
```

 $^{^{1}} assn_subX(X+1) (assn_subX(X+2)(X=3))$ $^{2} X=3$

in terms of the syntax of Hoare Logic derivations (provability) rather than directly in terms of the semantics of Hoare triples.

The first one says that, for every P and c, the assertion $\{\{P\}\}$ c $\{\{True\}\}$ is provable in Hoare Logic. Note that the proof is more complex than the semantic proof in Hoare: we actually need to perform an induction over the structure of the command c.

```
Theorem H_Post_True_deriv:
  \forall c P, hoare_proof P c (fun \_ \Rightarrow \mathsf{True}).
Proof.
  intro c.
  com\_cases (induction c) Case; intro P.
  Case "SKIP".
     eapply H_Consequence_pre.
     apply H_Skip.
     intros. apply |.
  Case "::=".
     eapply H_Consequence_pre.
     apply H_Asgn.
     intros. apply |.
  Case "; ".
     eapply H_Consequence_pre.
     eapply H_Seq.
     apply (IHc1 (fun \_ \Rightarrow True)).
     apply IHc2.
     intros. apply |.
  Case "IFB".
     apply H_{\text{consequence\_pre with (fun } \_ \Rightarrow \text{True}).
     apply H_lf.
     apply IHc1.
     apply IHc2.
     intros. apply |.
  Case "WHILE".
     eapply H_Consequence.
     eapply H_While.
     eapply IHc.
     intros; apply |.
     intros; apply |.
Qed.
   Similarly, we can show that \{\{False\}\}\ c\ \{\{Q\}\}\ is provable for any c and Q.
Lemma False_and_P_{imp}: \forall P Q,
  False \wedge P \rightarrow Q.
Proof.
  intros P Q [CONTRA HP].
```

```
destruct CONTRA.
Qed.
Tactic Notation "pre_false_helper" constr(CONSTR) :=
  eapply H_Consequence_pre;
    [eapply CONSTR | intros? CONTRA; destruct CONTRA].
Theorem H_Pre_False_deriv:
  \forall c \ Q, hoare_proof (fun \_ \Rightarrow False) c \ Q.
Proof.
  intros c.
  com\_cases (induction c) Case; intro Q.
  Case "SKIP". pre_false_helper H_Skip.
  Case "::=". pre_false_helper H_Asgn.
  Case ";". pre_false_helper H_Seq. apply IHc1. apply IHc2.
  Case "IFB".
    apply H_If; eapply H_Consequence_pre.
    apply IHc1. intro. eapply False_and_P_imp.
    apply IHc2. intro. eapply False_and_P_imp.
  Case "WHILE".
    eapply H_Consequence_post.
    eapply H_While.
    eapply H_Consequence_pre.
      apply IHc.
      intro. eapply False_and_P_imp.
    intro. simpl. eapply False_and_P_imp.
Qed.
```

This style of presentation gives a clearer picture of what it means to "give a proof in Hoare logic." However, it is not entirely satisfactory from the point of view of writing down such proofs in practice: it is quite verbose. The section of chapter *Hoare* on formalizing decorated programs shows how we can do even better.

Chapter 18

Library Rel

18.1 Rel: Properties of Relations

Require Export SfLib.

A (binary) relation is just a parameterized proposition. As you know from your undergraduate discrete math course, there are a lot of ways of discussing and describing relations in general – ways of classifying relations (are they reflexive, transitive, etc.), theorems that can be proved generically about classes of relations, constructions that build one relation from another, etc. Let us pause here to review a few that will be useful in what follows.

A (binary) relation on a set X is a proposition parameterized by two Xs – i.e., it is a logical assertion involving two values from the set X.

```
Definition relation (X: Type) := X \rightarrow X \rightarrow Prop.
```

Somewhat confusingly, the Coq standard library hijacks the generic term "relation" for this specific instance. To maintain consistency with the library, we will do the same. So, henceforth the Coq identifier *relation* will always refer to a binary relation between some set and itself, while the English word "relation" can refer either to the specific Coq concept or the more general concept of a relation between any number of possibly different sets. The context of the discussion should always make clear which is meant.

An example relation on *nat* is le, the less-that-or-equal-to relation which we usually write like this $n1 \leq n2$.

```
Print le.
Check le : nat \rightarrow nat \rightarrow Prop.
Check le : relation nat.
```

18.2 Basic Properties of Relations

A relation R on a set X is a partial function if, for every x, there is at most one y such that R x y - i.e., if R x y1 and R x y2 together imply y1 = y2.

```
Definition partial_function \{X : \mathtt{Type}\}\ (R : \mathtt{relation}\ X) := \forall x\ y1\ y2 : X,\ R\ x\ y1 \to R\ x\ y2 \to y1 = y2.
```

For example, the *next_nat* relation defined in Logic.v is a partial function.

However, the < relation on numbers is not a partial function.

This can be shown by contradiction. In short: Assume, for a contradiction, that \leq is a partial function. But then, since $0 \leq 0$ and $0 \leq 1$, it follows that 0 = 1. This is nonsense, so our assumption was contradictory.

```
Theorem le_not_a_partial_function:

¬ (partial_function le).

Proof.

unfold not. unfold partial_function. intros Hc.

assert (0 = 1) as Nonsense.

Case "Proof of assertion".

apply Hc with (x := 0).

apply le_n.

apply le_S. apply le_n.

inversion Nonsense. Qed.
```

Exercise: 2 stars, optional Show that the *total_relation* defined in Logic.v is not a partial function.

Exercise: 2 stars, optional Show that the *empty_relation* defined in Logic.v is a partial function.

A reflexive relation on a set X is one for which every element of X is related to itself.

```
Definition reflexive \{X \colon \mathsf{Type}\}\ (R \colon \mathsf{relation}\ X) := \forall \ a \colon X, \ R \ a \ a.
```

Theorem le_reflexive:

reflexive le.

Proof.

unfold reflexive. intros n. apply le_n . Qed.

A relation R is transitive if R a c holds whenever R a b and R b c do.

```
Definition transitive \{X \colon \mathsf{Type}\}\ (R \colon \mathsf{relation}\ X) := \forall \ a \ b \ c \colon X, \ (R \ a \ b) \to (R \ b \ c) \to (R \ a \ c).
```

Theorem le_trans:

transitive le.

Proof.

intros n m o Hnm Hmo.

```
induction Hmo.
  Case "le_n". apply Hnm.
  Case "le_S". apply le_S. apply IHHmo. Qed.
Theorem It_trans:
  transitive It.
Proof.
  unfold It. unfold transitive.
  intros n m o Hnm Hmo.
  apply le_S in Hnm.
  apply le_trans with (a := (S n)) (b := (S m)) (c := o).
  apply Hnm.
  apply Hmo. Qed.
Exercise: 2 stars, optional We can also prove lt_trans more laboriously by induction,
without using le_trans. Do this.
Theorem lt_trans':
  transitive It.
Proof.
  unfold It. unfold transitive.
  intros n m o Hnm Hmo.
  induction Hmo as [|m'Hm'o|].
   Admitted.
   Exercise: 2 stars, optional Prove the same thing again by induction on o.
Theorem lt_trans':
  transitive It.
Proof.
  unfold transitive.
  intros n m o Hnm Hmo.
  induction o as [ | o' ].
   Admitted.
   The transitivity of le, in turn, can be used to prove some facts that will be useful later
(e.g., for the proof of antisymmetry below)...
Theorem le_Sn_le: \forall n \ m, \ S \ n \leq m \rightarrow n \leq m.
Proof.
  intros n m H. apply le_{trans} with (S n).
    apply le_S. apply le_n.
    apply H. Qed.
```

Exercise: 1 star, optional Theorem $le_S_n : \forall n m$, $(S n \leq S m) \rightarrow (n \leq m).$ Proof. Admitted. Exercise: 2 stars, optional (le_Sn_n_inf) Provide an informal proof of the following theorem: Theorem: For every n, $(S \ n \leq n)$ A formal proof of this is an optional exercise below, but try the informal proof without doing the formal proof first. Proof: \square Exercise: 1 star, optional Theorem le_Sn_n : $\forall n$, \neg (S n < n). Proof. Admitted. Reflexivity and transitivity are the main concepts we'll need for later chapters, but, for a bit of additional practice working with relations in Coq, here are a few more common ones. A relation R is symmetric if R a b implies R b a. Definition symmetric $\{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=$ $\forall a \ b : X, (R \ a \ b) \rightarrow (R \ b \ a).$ Exercise: 2 stars, optional Theorem le_not_symmetric: ¬ (symmetric le). Proof. Admitted. A relation R is antisymmetric if R a b and R b a together imply a = b – that is, if the only "cycles" in R are trivial ones. Definition antisymmetric $\{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=$ $\forall a \ b : X, (R \ a \ b) \rightarrow (R \ b \ a) \rightarrow a = b.$ Exercise: 2 stars, optional Theorem le_antisymmetric: antisymmetric le. Proof. Admitted.

```
Exercise: 2 stars, optional Theorem le_step: \forall n \ m \ p,
  n < m \rightarrow
  m \leq S p \rightarrow
  n < p.
Proof.
    Admitted.
    A relation is an equivalence if it's reflexive, symmetric, and transitive.
Definition equivalence \{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=
   (reflexive R) \wedge (symmetric R) \wedge (transitive R).
    A relation is a partial order when it's reflexive, anti-symmetric, and transitive. In the
Cog standard library it's called just "order" for short.
Definition order \{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=
   (reflexive R) \wedge (antisymmetric R) \wedge (transitive R).
    A preorder is almost like a partial order, but doesn't have to be antisymmetric.
Definition preorder \{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) :=
   (reflexive R) \wedge (transitive R).
Theorem le_order:
  order le.
Proof.
  unfold order. split.
     Case "refl". apply le_reflexive.
     split.
        Case "antisym". apply le_antisymmetric.
        Case "transitive.". apply le_trans. Qed.
```

18.3 Reflexive, Transitive Closure

The reflexive, transitive closure of a relation R is the smallest relation that contains R and that is both reflexive and transitive. Formally, it is defined like this in the Relations module of the Coq standard library:

For example, the reflexive and transitive closure of the $next_nat$ relation coincides with the le relation.

```
Theorem next_nat_closure_is_le : \forall n m,
  (n \leq m) \leftrightarrow ((clos\_refl\_trans\ next\_nat)\ n\ m).
Proof.
  intros n m. split.
     Case "->".
       intro H. induction H.
       SCase "le_n". apply rt_refl.
       SCase "le_S".
         apply rt_trans with m. apply IHle. apply rt_step. apply nn.
     Case "<-".
       intro H. induction H.
       SCase "rt_step". inversion H. apply le_S. apply le_n.
       SCase "rt_refl". apply le_n.
       SCase "rt_trans".
         apply le_{trans} with y.
         apply IHclos_refl_trans1.
         apply IHclos_refl_trans2. Qed.
```

The above definition of reflexive, transitive closure is natural – it says, explicitly, that the reflexive and transitive closure of R is the least relation that includes R and that is closed under rules of reflexivity and transitivity. But it turns out that this definition is not very convenient for doing proofs – the "nondeterminism" of the rt_trans rule can sometimes lead to tricky inductions.

Here is a more useful definition...

```
Inductive refl_step_closure \{X : \texttt{Type}\}\ (R : \texttt{relation}\ X) : \texttt{relation}\ X := | \texttt{rsc\_refl}: \ \forall \ (x : X), \ \texttt{refl\_step\_closure}\ R \ x \ x | | \texttt{rsc\_step}: \ \forall \ (x \ y \ z : X), \\ R \ x \ y \rightarrow \\ \texttt{refl\_step\_closure}\ R \ y \ z \rightarrow \\ \texttt{refl\_step\_closure}\ R \ x \ z.
```

(Note that, aside from the naming of the constructors, this definition is the same as the *multi* step relation used in many other chapters.)

(The following Tactic Notation definitions are explained in Imp.v. You can ignore them if you haven't read that chapter yet.)

```
Tactic Notation "rt_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c "rt_step" | Case\_aux \ c "rt_refl" | Case\_aux \ c "rt_trans" ].

Tactic Notation "rsc_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c "rsc_refl" | Case\_aux \ c "rsc_step" ].
```

Our new definition of reflexive, transitive closure "bundles" the rt_step and rt_trans rules

into the single rule step. The left-hand premise of this step is a single use of R, leading to a much simpler induction principle.

Before we go on, we should check that the two definitions do indeed define the same relation...

First, we prove two lemmas showing that $refl_step_closure$ mimics the behavior of the two "missing" $clos_refl_trans$ constructors.

```
Theorem rsc_R : \forall (X:Type) (R:relation X) (x y : X),
         R \ x \ y \rightarrow \mathsf{refl\_step\_closure} \ R \ x \ y.
Proof.
  intros X R x y H.
  apply rsc_step with y. apply H. apply rsc_refl. Qed.
Exercise: 2 stars, optional (rsc_trans)
                                                   Theorem rsc_trans:
  \forall (X:Type) (R: relation X) (x y z : X),
       refl_step_closure R x y \rightarrow
       refl_step_closure R \ y \ z \rightarrow
       refl_step_closure R x z.
Proof.
   Admitted.
   Then we use these facts to prove that the two definitions of reflexive, transitive closure
do indeed define the same relation.
Exercise: 3 stars, optional (rtc_rsc_coincide) Theorem rtc_rsc_coincide:
           \forall (X:\mathsf{Type}) (R:\mathsf{relation}\ X) (x\ y:X),
  clos_refl_trans R x y \leftrightarrow \text{refl\_step\_closure } R x y.
Proof.
    Admitted.
```

Chapter 19

Library Smallstep

19.1 Smallstep: Small-step Operational Semantics

Require Export Imp.

The evaluators we have seen so far (e.g., the ones for *aexps*, *bexps*, and commands) have been formulated in a "big-step" style – they specify how a given expression can be evaluated to its final value (or a command plus a store to a final store) "all in one big step."

This style is simple and natural for many purposes (indeed, Gilles Kahn, who popularized its use, called it *natural semantics*), but there are some things it does not do well. In particular, it does not give us a natural way of talking about *concurrent* programming languages, where the "semantics" of a program – i.e., the essence of how it behaves – is not just which input states get mapped to which output states, but also includes the intermediate states that it passes through along the way, since these states can also be observed by concurrently executing code.

Another shortcoming of the big-step style is more technical, but critical for some applications. Consider the variant of Imp with lists that we introduced in ImpList.v. We chose to define the meaning of programs like 0 + nil by specifying that a list should be interpreted as 0 when it occurs in a context expecting a number, but this was a bit of a hack. It would be better simply to say that the behavior of such a program is undefined – it doesn't evaluate to any result. We could easily do this: we'd just have to use the formulations of aeval and beval as inductive propositions (rather than Fixpoints), so that we can make them partial functions instead of total ones.

However, this way of defining Imp has a serious deficiency. In this language, a command might *fail* to map a given starting state to any ending state for two quite different reasons: either because the execution gets into an infinite loop or because, at some point, the program tries to do an operation that makes no sense, such as taking the successor of a boolean variable, and none of the evaluation rules can be applied.

These two outcomes – nontermination vs. getting stuck in an erroneous configuration – are quite different. In particular, we want to allow the first (permitting the possibility of infinite loops is the price we pay for the convenience of programming with general looping

constructs like *while*) but prevent the second (which is just wrong), for example by adding some form of *typechecking* to the language. Indeed, this will be a major topic for the rest of the course. As a first step, we need a different way of presenting the semantics that allows us to distinguish nontermination from erroneous "stuck states."

So, for lots of reasons, we'd like to have a finer-grained way of defining and reasoning about program behaviors. This is the topic of the present chapter. We replace the "big-step" eval relation with a "small-step" relation that specifies, for a given program, how the "atomic steps" of computation are performed.

19.2 Relations

A relation on a set X is a family of propositions parameterized by two elements of X – i.e., a proposition about pairs of elements of X.

```
Definition relation (X: \mathsf{Type}) := X \rightarrow X \rightarrow \mathsf{Prop}.
```

Our main examples of such relations in this chapter will be the single-step and multi-step reduction relations on terms, ==> and ==>*, but there are many other examples – some that come to mind are the "equals," "less than," "less than or equal to," and "is the square of" relations on numbers, and the "prefix of" relation on lists and strings.

The optional *Rel* chapter tells a more detailed story about how relations are treated in Coq.

19.3 A Toy Language

To save space in the discussion, let's go back to an incredibly simple language containing just constants and addition. (We use single letters -C and P – for the constructor names, for brevity.) At the end of the chapter, we'll see how to apply the same techniques to the full Imp language.

```
Inductive \mathbf{tm}: \mathsf{Type} := | \mathsf{C}: \mathsf{nat} \to \mathsf{tm} | \mathsf{P}: \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}.

Tactic Notation "\mathsf{tm\_cases}" \mathit{tactic}(\mathsf{first}) \; \mathit{ident}(c) := \mathsf{first};
[ \mathit{Case\_aux} \; c \; \mathsf{"C"} \; | \; \mathit{Case\_aux} \; c \; \mathsf{"P"} \; ].

Module SIMPLEARITHO.
```

Here is a standard evaluator for this language, written in the same (big-step) style as we've been using up to this point.

```
Fixpoint eval (t: \mathbf{tm}) : \mathbf{nat} :=  match t with \mid \mathsf{C} \ n \Rightarrow n
```

```
\mid P a1 a2 \Rightarrow eval a1 + eval a2 end.
```

End SIMPLEARITHO.

Now, here is the same evaluator, written in exactly the same style, but formulated as an inductively defined relation. Again, we use the notation $t \mid\mid n$ for "t evaluates to n."

```
(E_Const) C n || n
    t1 || n1 t2 || n2
(E_Plus) P t1 t2 || C (n1 + n2)
Reserved Notation " t '||' n " (at level 50, left associativity).
Inductive eval: tm \rightarrow nat \rightarrow Prop :=
  \mid \mathsf{E}_{\mathsf{-}}\mathsf{Const} : \forall n,
        C n \mid \mid n
  \mid \mathsf{E}_{-}\mathsf{Plus} : \forall t1 \ t2 \ n1 \ n2,
        t1 \mid \mid n1 \rightarrow
        t2 \mid \mid n2 \rightarrow
        P t1 \ t2 \ | \ (n1 + n2)
  where " t '||' n " := (eval t n).
Tactic Notation "eval_cases" tactic(first) ident(c) :=
  first;
  [ Case\_aux \ c "E_Const" | Case\_aux \ c "E_Plus" ].
Module SIMPLEARITH1.
    Now, here is a small-step version.
(ST_PlusConstConst) P (C n1) (C n2) ==> C (n1 + n2)
    t1 ==> t1'
(ST_Plus1) P t1 t2 ==> P t1' t2
    t2 = > t2'
(ST_Plus2) P (C n1) t2 ==> P (C n1) t2'
Reserved Notation " t :==>' t' " (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  \mid \mathsf{ST}_{-}\mathsf{PlusConstConst}: \forall n1 \ n2,
        P(C n1)(C n2) ==> C(n1 + n2)
  | ST_Plus1 : \forall t1 \ t1' \ t2,
        t1 ==> t1' \rightarrow
        P t1 t2 ==> P t1' t2
```

```
| ST_Plus2 : \forall n1 \ t2 \ t2',
       t2 ==> t2' \rightarrow
      P(C n1) t2 ==> P(C n1) t2'
  where " t '==>' t' " := (step t \ t').
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first:
  [ Case_aux c "ST_PlusConstConst"
  | Case_aux c "ST_Plus1" | Case_aux c "ST_Plus2" ].
   Things to notice:
```

- We are defining just a single reduction step, in which one P node is replaced by its value.
- Each step finds the *leftmost P* node that is ready to go (both of its operands are constants) and rewrites it in place. The first rule tells how to rewrite this P node itself; the other two rules tell how to find it.
- A term that is just a constant cannot take a step.

A couple of examples of reasoning with the *step* relation...

If t1 can take a step to t1', then P t1 t2 steps to plus t1' t2:

```
Example test_step_1 :
```

```
Ρ
  (P(C 0)(C 3))
 (P(C2)(C4))
Ρ
 (C(0+3))
  (P(C2)(C4)).
```

Proof.

apply ST_Plus1. apply ST_PlusConstConst. Qed.

Exercise: 2 stars (test_step_2) Right-hand sides of sums can take a step only when the left-hand side is finished: if t2 can take a step to t2, then P(C n) t2 steps to P(C n)*t2*':

```
Example test_step_2 :
        (C 0)
         (P
           (C 2)
           (P(C 0)(C 3))
```

```
==>
P
(C 0)
(P
(C 2)
(C (0 + 3))).

Proof.

Admitted.
```

One simple property of the ==> relation is that, like the evaluation relation for our language of Imp programs, it is deterministic.

Theorem: For each t, there is at most one t' such that t steps to t' (t ==> t') is provable. Formally, this is the same as saying that ==> is deterministic.

Proof sketch: We show that if x steps to both y1 and y2 then y1 and y2 are equal, by induction on a derivation of $step \ x \ y1$. There are several cases to consider, depending on the last rule used in this derivation and in the given derivation of $step \ x \ y2$.

- If both are $ST_{-}PlusConstConst$, the result is immediate.
- The cases when both derivations end with ST_Plus1 or ST_Plus2 follow by the induction hypothesis.
- It cannot happen that one is $ST_PlusConstConst$ and the other is ST_Plus1 or ST_Plus2 , since this would imply that x has the form P t1 t2 where both t1 and t2 are constants (by $ST_PlusConstConst$) and one of t1 or t2 has the form P
- Similarly, it cannot happen that one is ST_Plus1 and the other is ST_Plus2 , since this would imply that x has the form P t1 t2 where t1 has both the form P t1 t2 and the form C n. \square

```
Definition deterministic \{X\colon \mathsf{Type}\}\ (R\colon \mathsf{relation}\ X) := \ \forall\ x\ y1\ y2 : X,\ R\ x\ y1 \to R\ x\ y2 \to y1 = y2.
Theorem step_deterministic:
    deterministic step.

    Case\ \mathsf{"ST\_PlusConstConst"}.\ step\_cases (inversion Hy2) SCase.
    SCase\ \mathsf{"ST\_PlusConstConst"}.\ reflexivity.
    SCase\ \mathsf{"ST\_Plus1"}.\ inversion\ H2.
    SCase\ \mathsf{"ST\_Plus2"}.\ inversion\ H2.
    Case\ \mathsf{"ST\_Plus1"}.\ step\_cases\ (inversion\ Hy2)\ SCase.
```

```
SCase \ "ST_PlusConstConst". \ rewrite \leftarrow H0 \ in \ Hy1. \ inversion \ Hy1. \\ SCase \ "ST_Plus1". \\ rewrite \leftarrow (IHHy1 \ t1'0). \\ reflexivity. \ assumption. \\ SCase \ "ST_Plus2". \ rewrite \leftarrow H \ in \ Hy1. \ inversion \ Hy1. \\ Case \ "ST_Plus2". \ step\_cases \ (inversion \ Hy2) \ SCase. \\ SCase \ "ST_PlusConstConst". \ rewrite \leftarrow H1 \ in \ Hy1. \ inversion \ Hy1. \\ SCase \ "ST_Plus1". \ inversion \ H2. \\ SCase \ "ST_Plus2". \\ rewrite \leftarrow (IHHy1 \ t2'0). \\ reflexivity. \ assumption. \ Qed.
```

End SIMPLEARITH1.

19.3.1 Values

Let's take a moment to slightly generalize the way we state the definition of single-step reduction.

It is useful to think of the ==> relation as defining an abstract machine:

- At any moment, the *state* of the machine is a term.
- A step of the machine is an atomic unit of computation here, a single "add" operation.
- The *halting states* of the machine are ones where there is no more computation to be done.

We can then execute a term t as follows:

- Take t as the starting state of the machine.
- Repeatedly use the ==> relation to find a sequence of machine states, starting with t, where each state steps to the next.
- When no more reduction is possible, "read out" the final state of the machine as the result of execution.

Intuitively, it is clear that the final states of the machine are always terms of the form C n for some n. We call such terms values.

```
Inductive value : tm \rightarrow Prop := v\_const : \forall n, value (C n).
```

Having introduced the idea of values, we can use it in the definition of the ==> relation to write ST_Plus2 rule in a slightly more elegant way:

```
(ST_PlusConstConst) P (C n1) (C n2) ==> C (n1 + n2)
```

```
t1 ==> t1'
```

```
(ST_Plus1) P t1 t2 ==> P t1' t2 value v1 t2 ==> t2'
```

(ST_Plus2) P v1 t2 ==> P v1 t2' Again, the variable names here carry important information: by convention, v1 ranges only over values, while t1 and t2 range over arbitrary terms. (Given this convention, the explicit value hypothesis is arguably redundant. We'll keep it for now, to maintain a close correspondence between the informal and Coq versions of the rules, but later on we'll drop it in informal rules, for the sake of brevity.)

Reserved Notation " t :==>' t' " (at level 40).

```
Inductive step : tm \rightarrow tm \rightarrow Prop :=
   ST_PlusConstConst: \forall n1 n2,
             P(C n1)(C n2)
       => C (n1 + n2)
  | ST_Plus1 : \forall t1 \ t1' \ t2,
          t1 ==> t1' \rightarrow
          P t1 t2 ==> P t1' t2
  | ST_Plus2 : \forall v1 \ t2 \ t2',
          value v1 \rightarrow
          t2 ==> t2' \rightarrow
          P v1 t2 ==> P v1 t2'
  where " t '==>' t' " := (step t \ t').
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first:
   Case_aux c "ST_PlusConstConst"
   Case_aux c "ST_Plus1" | Case_aux c "ST_Plus2" ].
```

Exercise: 3 stars, recommended (redo_determinism) As a sanity check on this change, let's re-verify determinism

Proof sketch: We must show that if x steps to both y1 and y2 then y1 and y2 are equal. Consider the final rules used in the derivations of $step \ x \ y1$ and $step \ x \ y2$.

- If both are $ST_PlusConstConst$, the result is immediate.
- It cannot happen that one is $ST_PlusConstConst$ and the other is ST_Plus1 or ST_Plus2 , since this would imply that x has the form P t1 t2 where both t1 and t2 are constants (by $ST_PlusConstConst$) AND one of t1 or t2 has the form P
- Similarly, it cannot happen that one is ST_Plus1 and the other is ST_Plus2 , since this would imply that x has the form P t1 t2 where t1 both has the form P t1 t2 and is a value (hence has the form C n).

• The cases when both derivations end with ST_Plus1 or ST_Plus2 follow by the induction hypothesis. \square

Most of this proof is the same as the one above. But to get maximum benefit from the exercise you should try to write it from scratch and just use the earlier one if you get stuck.

```
Exercise: 2 stars, optional (step_deterministic) Theorem step_deterministic : deterministic step. Proof.  Admitted.
```

19.3.2 Strong Progress and Normal Forms

The definition of single-step reduction for our toy language is fairly simple, but for a larger language it would be pretty easy to forget one of the rules and create a situation where some term cannot take a step even though it has not been completely reduced to a value. The following theorem shows that we did not, in fact, make such a mistake here.

Theorem (Strong Progress): For all t:tm, either t is a value, or there exists a term t' such that t ==> t'.

Proof: By induction on t.

- Suppose t = C n. Then t is a value.
- Suppose $t = P \ t1 \ t2$, where (by the IH) t1 is either a value or can step to some t1, and where t2 is either a value or can step to some t2. We must show $P \ t1 \ t2$ is either a value or steps to some t.
 - If t1 and t2 are both values, then t can take a step, by $ST_PlusConstConst$.
 - If t1 is a value and t2 can take a step, then so can t, by ST_Plus2 .
 - If t1 can take a step, then so can t, by ST_-Plus1 . \square

```
Theorem strong_progress : \forall t, value t \lor (\exists t', t ==> t').

Proof.

tm\_cases (induction t) Case.

Case "C". left. apply v_const.

Case "P". right. inversion IHt1.

SCase "l". inversion IHt2.

SSCase "l". inversion H. inversion H0.

\exists (C (n + n\theta)).

apply ST\_PlusConstConst.
```

```
SSCase "r". inversion H0 as [t' H1].

\exists (P t1 t').

apply ST_Plus2. apply H. apply H1.

SCase "r". inversion H as [t' H0].

\exists (P t' t2).

apply ST_Plus1. apply H0. Qed.
```

This important property is called *strong progress*, because every term either is a value or can "make progress" by stepping to some other term. (The qualifier "strong" distinguishes it from a more refined version that we'll see in later chapters, called simply "progress.")

The idea of "making progress" can be extended to tell us something interesting about values: in this language values are exactly the terms that cannot make progress in this sense. To state this fact, let's begin by giving a name to terms that cannot make progress: We'll call them normal forms.

```
Definition normal_form \{X: \mathtt{Type}\}\ (R: \mathtt{relation}\ X)\ (t:X): \mathtt{Prop} := \neg \exists \ t', \ R \ t \ t'.
```

This definition actually specifies what it is to be a normal form for an *arbitrary* relation R over an arbitrary set X, not just for the particular single-step reduction relation over terms that we are interested in at the moment. We'll re-use the same terminology for talking about other relations later in the course.

We can use this terminology to generalize the observation we made in the strong progress theorem: in this language, normal forms and values are actually the same thing.

```
Lemma value_is_nf : \forall t,
  value t \rightarrow \text{normal\_form step } t.
Proof.
  unfold normal_form. intros t H. inversion H.
  intros contra. inversion contra. inversion H1.
Qed.
Lemma nf_{is}-value : \forall t,
  normal_form step t \rightarrow \text{value } t.
           unfold normal_form. intros t\ H.
  assert (G : \mathsf{value}\ t \lor \exists\ t',\ t ==> t').
     SCase "Proof of assertion". apply strong_progress.
  inversion G.
     SCase "l". apply H0.
     SCase "r". apply ex_falso_quodlibet. apply H. assumption. Qed.
Corollary nf_{same_as_value} : \forall t,
  normal_form step t \leftrightarrow \text{value } t.
Proof.
  split. apply nf_is_value. apply value_is_nf. Qed.
    Why is this interesting? For two reasons:
```

- Because *value* is a syntactic concept it is a defined by looking at the form of a term while *normal_form* is a semantic one it is defined by looking at how the term steps. It is not obvious that these concepts should coincide!
- Indeed, there are lots of languages in which the concepts of normal form and value do not coincide.

Let's examine how this can happen...

We might, for example, mistakenly define *value* so that it includes some terms that are not finished reducing.

```
Module TEMP1.
```

```
Inductive value : tm \rightarrow Prop :=
| v_{\text{-}} const : \forall n, value (C n)
| \mathbf{v}_{\mathsf{-}} \mathsf{funny} : \forall t1 \ n2,
                    value (P t1 (C n2)).
Reserved Notation "t'==>'t' (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
   | ST_PlusConstConst : \forall n1 n2,
         P(C n1)(C n2) \Longrightarrow C(n1 + n2)
   | ST_Plus1 : \forall t1 \ t1' \ t2,
        t1 ==> t1' \rightarrow
         P t1 t2 ==> P t1' t2
   | ST_Plus2 : \forall v1 \ t2 \ t2',
        value v1 \rightarrow
         t2 ==> t2' \rightarrow
        P v1 t2 ==> P v1 t2'
   where " t '==>' t' " := (step t \ t').
```

Exercise: 3 stars, optional (value_not_same_as_normal_form) Lemma value_not_same_as_normal_

 \exists t, value $t \land \neg$ normal_form step t.

Proof.

Admitted.

End TEMP1.

Alternatively, we might mistakenly define *step* so that it permits something designated as a value to reduce further.

Module TEMP2.

Inductive value : $tm \rightarrow Prop :=$

```
| v_{\text{-}} const : \forall n, value (C n).
Reserved Notation "t'==>'t' (at level 40).
\mathtt{Inductive}\ \textbf{step}:\ \textbf{tm}\to\textbf{tm}\to\mathtt{Prop}:=
  \mid \mathsf{ST}_{\mathsf{Funny}} : \forall n,
        C n \Longrightarrow P (C n) (C 0)
  | ST_PlusConstConst : \forall n1 n2,
        P(C n1)(C n2) \Longrightarrow C(n1 + n2)
  | ST_Plus1 : \forall t1 \ t1' \ t2,
        t1 ==> t1' \rightarrow
        P t1 t2 ==> P t1' t2
  | ST_Plus2 : \forall v1 \ t2 \ t2',
        value v1 \rightarrow
        t2 ==> t2' \rightarrow
        P v1 t2 ==> P v1 t2'
  where " t '==>' t' " := (step t \ t').
Exercise: 2 stars, optional (value_not_same_as_normal_form) Lemma value_not_same_as_normal_
  \exists t, value t \land \neg normal_form step t.
Proof.
    Admitted.
    End TEMP2.
    Finally, we might define value and step so that there is some term that is not a value but
that cannot take a step in the step relation. Such terms are said to be stuck. In this case
```

this is caused by a mistake in the semantics, but we will also see situations where, evne in a correct language definition, it makes sense to allow some terms to be stuck.

Module TEMP3.

```
Inductive value : tm \rightarrow Prop :=
  | v_{\text{-}} const : \forall n, value (C n).
Reserved Notation "t'==>'t' (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_PlusConstConst : \forall n1 n2,
        P(C n1)(C n2) ==> C(n1 + n2)
  | ST_Plus1 : \forall t1 \ t1' \ t2,
        t1 \Longrightarrow t1' \rightarrow
        P t1 t2 ==> P t1' t2
  where " t' = > t' " := (step t t').
```

```
(Note that ST\_Plus2 is missing.)
```

```
Exercise: 3 \text{ stars (value\_not\_same\_as\_normal\_form')} Lemma value\_not_same_as_normal_form: \exists t, \neg \text{ value } t \land \text{ normal\_form step } t. Proof. Admitted. \Box End TEMP3.
```

Additional Exercises

Module TEMP4.

Here is another very simple language whose terms, instead of being just plus and numbers, are just the booleans true and false and a conditional expression...

```
Inductive tm : Type :=
   ttrue : tm
    tfalse : tm
   | tif : tm \rightarrow tm \rightarrow tm \rightarrow tm.
Inductive value : tm \rightarrow Prop :=
   | v_true : value ttrue
   | v_false : value tfalse.
Reserved Notation " t '==>' t' " (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
   \mid \mathsf{ST\_IfTrue} : \forall t1 \ t2,
        tif ttrue t1 t2 ==> t1
   \mid ST_IFFalse : \forall t1 t2,
        tif tfalse t1 t2 ==> t2
  \mid ST_If : \forall t1 t1' t2 t3,
        t1 ==> t1' \rightarrow
        tif t1 t2 t3 ==> tif t1' t2 t3
   where " t '==>' t' " := (step t \ t').
```

Exercise: 1 star (smallstep_bools) Which of the following propositions are provable? (This is just a thought exercise, but for an extra challenge feel free to prove your answers in Coq.)

```
Definition bool_step_prop1 :=
   tfalse ==> tfalse.
Definition bool_step_prop2 :=
```

```
tif
        ttrue
         (tif ttrue ttrue ttrue)
         (tif tfalse tfalse tfalse)
  ==>
      ttrue.
Definition bool_step_prop3 :=
      tif
         (tif ttrue ttrue ttrue)
         (tif ttrue ttrue ttrue)
        tfalse
   ==>
      tif
        ttrue
        (tif ttrue ttrue ttrue)
        tfalse.
```

Exercise: 3 stars, recommended (progress_bool) Just as we proved a progress theorem for plus expressions, we can do so for boolean expressions, as well.

```
Theorem strong_progress : \forall t, value t \lor (\exists t', t ==> t'). Proof.

Admitted.
```

Exercise: 2 stars, optional (step_deterministic) Theorem step_deterministic : deterministic step.

Proof.

Admitted.

Module TEMP5.

Exercise: 2 stars (smallstep_bool_shortcut) Suppose we want to add a "short circuit" to the step relation for boolean expressions, so that it can recognize when the then and else branches of a conditional are the same value (either ttrue or tfalse) and reduce the whole conditional to this value in a single step, even if the guard has not yet been reduced to a value. For example, we would like this proposition to be provable: tif (tif ttrue ttrue ttrue) tfalse tfalse ==> tfalse.

Write an extra clause for the step relation that achieves this effect and prove bool_step_prop4.

```
Reserved Notation "t'==>'t' (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_IfTrue : \forall t1 t2,
       tif ttrue t1 t2 ==> t1
  | ST_IfFalse : \forall t1 t2,
       tif tfalse t1 t2 ==> t2
  | ST_If : \forall t1 t1' t2 t3,
       t1 ==> t1' \rightarrow
       tif t1 t2 t3 ==> tif t1' t2 t3
  where " t' = > t' " := (step t t').
   Definition bool_step_prop4 :=
           tif
               (tif ttrue ttrue ttrue)
               tfalse
               tfalse
      ==>
           tfalse.
Example bool_step_prop4_holds :
  bool_step_prop4.
Proof.
    Admitted.
```

Exercise: 3 stars, optional (properties_of_altered_step) It can be shown that the determinism and strong progress theorems for the step relation in the lecture notes also hold for the definition of step given above. After we add the clause $ST_ShortCircuit...$

• Is the *step* relation still deterministic? Write yes or no and briefly (1 sentence) explain your answer.

Optional: prove your answer correct in Coq.

• Does a strong progress theorem hold? Write yes or no and briefly (1 sentence) explain your answer.

Optional: prove your answer correct in Coq.

• In general, is there any way we could cause strong progress to fail if we took away one or more constructors from the original step relation? Write yes or no and briefly (1 sentence) explain your answer.

End TEMP5. End TEMP4.

19.4 Multi-Step Reduction

Until now, we've been working with the $single-step\ reduction\ relation ==>$, which formalizes the individual steps of an $abstract\ machine\ for\ executing\ programs$.

We can also use this machine to reduce programs to completion – to find out what final result they yield. This can be formalized as follows:

- First, we define a multi-step reduction relation $==>^*$, which relates terms t and t' if t can reach t' by any number of single reduction steps (including zero steps!).
- ullet Then we define a "result" of a term t as a normal form that t can reach by multi-step reduction.

19.4.1 Definitions

Since we'll want to reuse the idea of multi-step reduction many times in this and future chapters, let's take a little extra trouble here and define it generically. Given a relation R, we define a relation $multi\ R$ as follows:

```
Inductive multi \{X: \mathsf{Type}\}\ (R: \mathsf{relation}\ X) : \mathsf{relation}\ X := |\mathsf{multi\_refl}: \ \forall \ (x:X), \ \mathsf{multi}\ R\ x\ x | \mathsf{multi\_step}: \ \forall \ (x\ y\ z:X), \ R\ x\ y \to \mathsf{multi}\ R\ y\ z \to \mathsf{multi}\ R\ x\ z.
```

The effect of this definition is that $multi\ R$ relates two elements x and y of X if either x = y or else there is some (possibly empty) sequence $z1,\ z2,\ ...,\ zn$ such that: R x z1 R z1 z2 ... R zn y

```
Tactic Notation "multi_cases" tactic(\texttt{first}) \ ident(c) := \ \texttt{first}; [ Case\_aux \ c "multi_refl" | Case\_aux \ c "multi_step" ]. Theorem multi_R : \forall \ (X:\texttt{Type}) \ (R:\texttt{relation} \ X) \ (x \ y : X), \ R \ x \ y \to (\texttt{multi} \ R) \ x \ y. Proof. intros X \ R \ x \ y \ H. apply multi_step with y. apply H. apply multi_refl. Qed. The crucial properties of the multi \ R relation are
```

- \bullet multi R is reflexive
- \bullet multi R is transitive
- $multi\ R$ relates everything related by R

We now write $==>^*$ for the *multi step* relation – i.e., the relation that relates two terms t and t' if we can get from t to t' using the step relation zero or more times.

```
Definition multistep := multi step.
Notation " t '==>*' t' " := (multistep t t') (at level 40).
```

19.4.2 Examples

```
apply multi_R.
  apply ST_PlusConstConst. Qed.
   Here's an alternate proof that uses eapply to avoid explicitly constructing all the inter-
mediate terms.
Lemma test_multistep_1':
        (P(C 0)(C 3))
        (P(C2)(C4))
  ==>*
      C((0+3)+(2+4)).
Proof.
  eapply multi_step. apply ST_Plus1. apply ST_PlusConstConst.
  eapply multi_step. apply ST_Plus2. apply v_const.
  apply ST_PlusConstConst.
  eapply multi_step. apply ST_PlusConstConst.
  apply multi_refl. Qed.
Exercise: 1 star, optional (test_multistep_2) Lemma test_multistep_2:
  C 3 ==>* C 3.
Proof.
   Admitted.
   Exercise: 1 star, optional (test_multistep_3) Lemma test_multistep_3:
      P (C 0) (C 3)
   ==>*
      P (C 0) (C 3).
Proof.
   Admitted.
   Exercise: 2 stars (test_multistep_4) Lemma test_multistep_4:
        (C 0)
        (P
          (C 2)
          (P (C 0) (C 3)))
        (C 0)
        (C(2 + (0 + 3))).
```

apply ST_PlusConstConst.

```
Proof. Admitted.
```

19.4.3 Normal Forms Again

 $(t ==> * t' \land step_normal_form t').$

If t reduces to t' in zero or more steps and t' is a normal form, we say that "t' is a normal form of t."

```
Definition step_normal_form := normal_form step. 
 Definition normal_form_of (t\ t': \mathbf{tm}) :=
```

We have already seen that, for our language, single-step reduction is deterministic – i.e., a given term can take a single step in at most one way. It follows from this that, if t can reach a normal form, then this normal form is unique. In other words, we can actually pronounce $normal_form\ t\ t'$ as "t' is the normal form of t."

Exercise: 3 stars, optional (normal_forms_unique) Theorem normal_forms_unique: deterministic normal_form_of.

Proof.

```
unfold deterministic. unfold normal_form_of. intros x y1 y2 P1 P2. inversion P1 as [P11 P12]; clear P1. inversion P2 as [P21 P22]; clear P2. generalize dependent y2. Admitted.
```

Indeed, something stronger is true for this language (though not for all languages): the reduction of any term t will eventually reach a normal form – i.e., $normal_form_of$ is a total function. Formally, we say the step relation is normalizing.

```
Definition normalizing \{X: \texttt{Type}\}\ (R: \texttt{relation}\ X) := \forall\ t, \ \exists\ t', \ (\texttt{multi}\ R)\ t\ t' \land \texttt{normal\_form}\ R\ t'.
```

To prove that *step* is normalizing, we need a couple of lemmas.

First, we observe that, if t reduces to t' in many steps, then the same sequence of reduction steps within t is also possible when t appears as the left-hand child of a P node, and similarly when t appears as the right-hand child of a P node whose left-hand child is a value.

```
Lemma multistep_congr_1 : \forall \ t1 \ t1' \ t2, t1 ==>* \ t1' \rightarrow P t1 \ t2 ==>* \ P \ t1' \ t2.

Proof.

intros t1 \ t1' \ t2 \ H. \ multi\_cases (induction H) Case.

Case \ "multi\_refl". apply multi_refl.
```

```
Case "multi_step". apply multi_step with (P y t2).
         apply ST_Plus1. apply H.
         apply IHmulti. Qed.
Exercise: 2 stars (multistep_congr_2) Lemma multistep_congr_2: \forall t1 \ t2 \ t2,
     value t1 \rightarrow
     t2 ==>* t2' \rightarrow
     P t1 t2 ==>* P t1 t2'.
Proof.
   Admitted.
   Theorem: The step function is normalizing – i.e., for every t there exists some t' such
that t steps to t' and t' is a normal form.
   Proof sketch: By induction on terms. There are two cases to consider:
   • t = C n for some n. Here t doesn't take a step, and we have t' = t. We can derive
```

the left-hand side by reflexivity and the right-hand side by observing (a) that values are normal forms (by $nf_same_as_value$) and (b) that t is a value (by v_const).

• $t = P \ t1 \ t2$ for some t1 and t2. By the IH, t1 and t2 have normal forms t1' and t2'. Recall that normal forms are values (by $nf_same_as_value$); we know that t1' = C n1and t2' = C n2, for some n1 and n2. We can combine the $==>^*$ derivations for t1and t2 to prove that P t1 t2 reduces in many steps to C(n1 + n2).

It is clear that our choice of t' = C (n1 + n2) is a value, which is in turn a normal form. \square

```
Theorem step_normalizing:

19.4.4 Equivalence of Big-Step and Small-Step Reduction

Having defined the operational semantics of our tiny programming language in two different styles, it makes sense to ask whether these definitions actually define the same thing! They do, though it takes a little work to show it. The details are left to you.

```
Exercise: 3 stars (eval__multistep) Theorem eval__multistep : \forall t \ n, t \mid \mid n \rightarrow t => * C \ n.
```

The key idea behind the proof comes from the following picture: P t1 t2 ==> (by ST_Plus1) P t1' t2 ==> (by ST_Plus1) P t1' t2 ==> (by ST_Plus1) ... P (C n1) t2 ==> (by ST_Plus2) P (C n1) t2' ==> (by ST_Plus2) P (C n1) t2'' ==> (by ST_Plus2) ... P (C n1) (C n2) ==> (by ST_PlusConstConst) C (n1 + n2) That is, the multistep reduction of a term of the form P t1 t2 proceeds in three phases:

- First, we use ST_-Plus1 some number of times to reduce t1 to a normal form, which must (by $nf_-same_-as_-value$) be a term of the form C n1 for some n1.
- Next, we use ST_-Plus2 some number of times to reduce t2 to a normal form, which must again be a term of the form C n2 for some n2.
- Finally, we use $ST_PlusConstConst$ one time to reduce P(C n1)(C n2) to C(n1 + n2).

To formalize this intuition, you'll need to use the congruence lemmas from above (you might want to review them now, so that you'll be able to recognize when they are useful), plus some basic properties of ==>*: that it is reflexive, transitive, and includes ==>.

Proof.

Admitted.

Exercise: 3 stars (eval__multistep_inf) Write a detailed informal version of the proof of eval__multistep.

For the other direction of the correspondence, we need one lemma, which establishes a relation between single-step reduction and big-step evaluation.

```
Exercise: 3 stars (step__eval) Lemma step__eval : \forall \ t \ t' \ n, t ==> t' \rightarrow t' \mid \mid n \rightarrow t \mid \mid n.

Proof.

intros t \ t' \ n \ Hs. generalize dependent n.

Admitted.
```

The main theorem is now straightforward to prove, once it is stated correctly. The proof proceeds by induction on the multipstep reduction sequence that is buried in the hypothesis $normal_form_of\ t\ v$. Make sure you understand the statement before you start to work on the proof.

```
Exercise: 3 stars (multistep__eval) Theorem multistep__eval : \forall \ t \ v, normal_form_of t \ v \to \exists \ n, v = C \ n \land t \mid \mid n.

Proof.

Admitted.
```

19.4.5 Additional Exercises

Exercise: 4 stars (combined_properties) We've considered the arithmetic and conditional expressions separately. This exercise explores how the two interact.

Module COMBINED.

```
Inductive tm: Type := |C: nat \rightarrow tm|
|P: tm \rightarrow tm \rightarrow tm|
|ttrue: tm|
|tfalse: tm|
|tif: tm \rightarrow tm \rightarrow tm \rightarrow tm.

Tactic Notation "tm_cases" tactic(first) \ ident(c) := first;
|Case\_aux \ c "C" |Case\_aux \ c "P"
|Case\_aux \ c "ttrue" |Case\_aux \ c "tfalse" |Case\_aux \ c "tif" |Case\_aux \ c "
```

```
v_{\text{-}}const : \forall n, value (C n)
    v_true : value ttrue
   | v_false : value tfalse.
Reserved Notation "t'==>'t' (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_PlusConstConst : \forall n1 n2,
       P(C n1)(C n2) \Longrightarrow C(n1 + n2)
  | ST_Plus1 : \forall t1 \ t1' \ t2,
       t1 ==> t1' \rightarrow
       P t1 t2 ==> P t1' t2
  | ST_Plus2 : \forall v1 \ t2 \ t2',
       value v1 \rightarrow
       t2 ==> t2' \rightarrow
       P v1 t2 ==> P v1 t2'
  | ST_IfTrue : \forall t1 t2,
       tif ttrue t1 t2 ==> t1
  | ST_IfFalse : \forall t1 t2,
       tif tfalse t1 t2 ==> t2
  \mid ST_If : \forall t1 t1' t2 t3,
       t1 ==> t1' \rightarrow
       tif t1 t2 t3 ==> tif t1' t2 t3
  where " t '==>' t' " := (step t \ t').
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first;
  [ Case_aux c "ST_PlusConstConst"
    Case\_aux\ c "ST_Plus1" | Case\_aux\ c "ST_Plus2"
   | Case_aux c "ST_IfTrue" | Case_aux c "ST_IfFalse" | Case_aux c "ST_If" |.
   Earlier, we separately proved for both plus- and if-expressions...
```

- that the step relation was deterministic, and
- a strong progress lemma, stating that every term is either a value or can take a step.

Prove or disprove these two properties for the combined language.

End COMBINED.

19.5 Small-Step Imp

For a more serious example, here is the small-step version of the Imp operational semantics.

The small-step evaluation relations for arithmetic and boolean expressions are straightforward extensions of the tiny language we've been working up to now. To make them easier to read, we introduce the symbolic notations ==>a and ==>b, respectively, for the arithmetic and boolean step relations.

```
Inductive aval : aexp \rightarrow Prop := av_num : \forall n, aval (ANum n).
```

We are not actually going to bother to define boolean values – they aren't needed in the definition of ==>b below (why?), though they might be if our language were a bit larger (why?).

```
Reserved Notation "t'/'st'==>a't' "(at level 40, st at level 39).
Inductive astep : state \rightarrow aexp \rightarrow aexp \rightarrow Prop :=
  \mid \mathsf{AS\_Id} : \forall st i,
        Ald i / st ==>a ANum (st i)
  \mid \mathsf{AS\_Plus} : \forall st \ n1 \ n2
        APlus (ANum n1) (ANum n2) / st ==>a ANum (n1 + n2)
  | AS_Plus1 : \forall st a1 a1' a2,
        a1 / st ==> a a1' \rightarrow
        (APlus a1 a2) / st ==>a (APlus a1' a2)
  \mid \mathsf{AS\_Plus2} : \forall st \ v1 \ a2 \ a2',
        aval v1 \rightarrow
        a2 / st ==> a a2' \rightarrow
        (APlus v1 a2) / st ==>a (APlus v1 a2')
  \mid \mathsf{AS\_Minus} : \forall st \ n1 \ n2,
        (AMinus (ANum n1) (ANum n2)) / st ==>a (ANum (minus n1 n2))
  \mid AS\_Minus1 : \forall st a1 a1' a2,
        a1 / st ==> a a1' \rightarrow
        (AMinus a1 a2) / st ==>a (AMinus a1' a2)
  \mid AS\_Minus2 : \forall st v1 a2 a2',
        aval v1 \rightarrow
        a2 / st ==>a a2' \rightarrow
        (AMinus v1 a2) / st ==>a (AMinus v1 a2')
  \mid \mathsf{AS\_Mult} : \forall st \ n1 \ n2,
        (AMult (ANum n1) (ANum n2)) / st ==>a (ANum (mult n1 n2))
  \mid \mathsf{AS\_Mult1} : \forall st \ a1 \ a1' \ a2,
        a1 / st ==> a a1' \rightarrow
        (\mathsf{AMult}\ (a1)\ (a2))\ /\ st ==> a\ (\mathsf{AMult}\ (a1')\ (a2))
  AS_Mult2: \forall st v1 a2 a2',
        aval v1 \rightarrow
        a2 / st ==> a a2' \rightarrow

      (BAnd b1 b2) / st ==>b (BAnd b1' b2)
```

```
where " t '/' st '==>b' t' " := (bstep st \ t').
```

The semantics of commands is the interesting part. We need two small tricks to make it work:

- We use SKIP as a "command value" i.e., a command that has reached a normal form.
 - An assignment command reduces to SKIP (and an updated state).
 - The sequencing command waits until its left-hand subcommand has reduced to SKIP, then throws it away so that reduction can continue with the right-hand subcommand.
- We reduce a WHILE command by transforming it into a conditional followed by the same WHILE.

(There are other ways of achieving the effect of the latter trick, but they all share the feature that the original *WHILE* command needs to be saved somewhere while a single copy of the loop body is being evaluated.)

```
Reserved Notation " t '/' st '==>' t' '/' st' "
                       (at level 40, st at level 39, t' at level 39).
Inductive cstep: (com \times state) \rightarrow (com \times state) \rightarrow Prop :=
  \mid \mathsf{CS\_AssStep} : \forall \ st \ i \ a \ a',
       a / st ==> a a' \rightarrow
        (i ::= a) / st ==> (i ::= a') / st
  \mid \mathsf{CS\_Ass} : \forall st \ i \ n,
        (i ::= (ANum n)) / st ==> SKIP / (update st i n)
  | CS\_SegStep : \forall st c1 c1' st' c2,
       c1 / st ==> c1' / st' \rightarrow
        (c1; c2) / st ==> (c1'; c2) / st'
  \mid \mathsf{CS\_SegFinish} : \forall st \ c2,
        (SKIP; c2) / st ==> c2 / st
  | CS_IfTrue : \forall st c1 c2,
       IFB BTrue THEN c1 ELSE c2 FI / st ==> c1 / st
  | CS_IfFalse : \forall st c1 c2,
       IFB BFalse THEN c1 ELSE c2 FI / st ==> c2 / st
  | CS_IfStep : \forall st b b' c1 c2,
       b / st ==>b b' \rightarrow
       IFB b THEN c1 ELSE c2 FI / st ==> (IFB b' THEN c1 ELSE c2 FI) / st
  | CS_While : \forall st \ b \ c1,
             (WHILE b DO c1 END) / st
       ==> (IFB b THEN (c1; (WHILE b DO c1 END)) ELSE SKIP FI) / st
  where "t'/'st'==>'t''/'st'" := (cstep (t,st) (t',st')).
```

19.6 Concurrent Imp (Optional)

Finally, to show the power of this definitional style, let's enrich Imp with a new form of command that runs two subcommands in parallel and terminates when both have terminated. To reflect the unpredictability of scheduling, the actions of the subcommands may be interleaved in any order, but they share the same memory and can communicate by reading and writing the same variables.

Module CIMP.

Chapter 20

Library Types

20.1 Types: Type Systems

Require Export Smallstep.

Our next topic, a large one, is *type systems* – static program analyses that classify expressions according to the "shapes" of their results. We'll begin with a typed version of a very simple language with just booleans and numbers, to introduce the basic ideas of types, typing rules, and the fundamental theorems about type systems: *type preservation* and *progress*. Then we'll move on to the *simply typed lambda-calculus*, which lives at the core of every modern functional programming language (including Coq).

20.2 More Automation

Before we start, let's spend a little time learning to use some of Coq's more powerful automation features...

20.2.1 The auto and eauto Tactics

The auto tactic solves goals that are solvable by any combination of

- intros,
- apply (with a local hypothesis, by default), and
- reflexivity.

The eauto tactic works just like auto, except that it uses eapply instead of apply. Using auto is always "safe" in the sense that it will never fail and will never change the proof state: either it completely solves the current goal, or it does nothing.

Here is a contrived example:

```
\begin{array}{l} \mathsf{Lemma\ auto\_example\_1}: \ \forall\ P\ Q\ R\ S\ T\ U: \mathsf{Prop}, \\ (P \to Q) \to \\ (P \to R) \to \\ (T \to R) \to \\ (S \to T \to U) \to \\ ((P \to Q) \to (P \to S)) \to \\ T \to \\ P \to \\ U. \end{array}
```

Proof. auto. Qed.

When searching for potential proofs of the current goal, auto and eauto consider the hypotheses in the current context together with a *hint database* of other lemmas and constructors. Some of the lemmas and constructors we've already seen - e.g., conj, or_introl , and or_intror - are installed in this hint database by default.

```
\label{eq:lemma_example_2} \begin{array}{c} \mathsf{Lemma\ auto\_example\_2}: \ \forall\ P\ Q\ R: \mathsf{Prop},\\ Q \to \\ (Q \to R) \to \\ P \lor (Q \land R). \\ \\ \mathsf{Proof.}\\ \\ \mathsf{auto.}\ \mathsf{Qed.} \end{array}
```

We can extend the hint database just for the purposes of one application of auto or eauto by writing auto using E.g., if *conj*, *or_introl*, and *or_intror* had *not* already been in the hint database, we could have done this instead:

```
Lemma auto_example_2a : \forall \ P \ Q \ R : Prop, Q \to (Q \to R) \to P \lor (Q \land R). Proof. auto using conj, or_introl, or_intror. Qed.
```

Of course, in any given development there will also be some of our own specific constructors and lemmas that are used very often in proofs. We can add these to the global hint database by writing Hint Resolve T. at the top level, where T is a top-level theorem or a constructor of an inductively defined proposition (i.e., anything whose type is an implication). As a shorthand, we can write Hint Constructors c. to tell Coq to do a Hint Resolve for all of the constructors from the inductive definition of c.

It is also sometimes necessary to add Hint Unfold d. where d is a defined symbol, so that auto knows to expand uses of d and enable further possibilities for applying lemmas that it knows about.

Here are some Hints we will find useful.

Hint Constructors multi.
Hint Resolve beq_id_eq beq_id_false_not_eq.

Warning: Just as with Coq's other automation facilities, it is easy to overuse auto and eauto and wind up with proofs that are impossible to understand later!

Also, overuse of eauto can make proof scripts very slow. Get in the habit of using auto most of the time and eauto only when necessary.

For much more detailed information about using auto and eauto, see the chapter Use-Auto.

20.2.2 The Proof with Tactic

If you start a proof by saying Proof with (tactic) instead of just Proof, then writing ... instead of . after a tactic in the body of the proof will try to solve all generated subgoals with tactic (and fail if this doesn't work).

One common use of this facility is "Proof with auto" (or eauto). We'll see many examples of this later in the file.

20.2.3 The solve by inversion Tactic

Here's another nice automation feature: it often arises that the context contains a contradictory assumption and we want to use inversion on it to solve the goal. We'd like to be able to say to Coq, "find a contradictory assumption and invert it" without giving its name explicitly.

Doing solve by inversion will find a hypothesis that can be inverted to solve the goal, if there is one. The tactics solve by inversion 2 and solve by inversion 3 are slightly fancier versions which will perform two or three inversions in a row, if necessary, to solve the goal.

(These tactics are not actually built into Coq – their definitions are in *Sflib*.) Caution: Overuse of solve by inversion can lead to slow proof scripts.

20.2.4 The try solve Tactic

If t is a tactic, then try solve [t] is a tactic that

- \bullet if t solves the goal, behaves just like t, or
- ullet if t cannot completely solve the goal, does nothing.

More generally, try solve $[t1 \mid t2 \mid ...]$ will try to solve the goal by using t1, t2, etc. If none of them succeeds in completely solving the goal, then try solve $[t1 \mid t2 \mid ...]$ does nothing.

20.2.5 The f_equal Tactic

f_equal replaces a goal of the form f x1 x2 ... xn = f y1 y2 ... yn, where f is some function, with the subgoals x1 = y1, x2 = y2,...,xn = yn. It is useful for avoiding explicit rewriting steps, and often the generated subgoals can be quickly cleared by auto. This tactic is not fundamental, in the sense that it can always be replaced by a sequence of asserts. However in some cases it can be very handy.

20.2.6 The normalize Tactic

When experimenting with definitions of programming languages in Coq, we often want to see what a particular concrete term steps to – i.e., we want to find proofs for goals of the form $t ==>^* t'$, where t is a completely concrete term and t' is unknown. These proofs are simple but repetitive to do by hand. Consider for example reducing an arithmetic expression using the small-step relation *astep* defined in the previous chapter:

```
Definition amultistep st := \text{multi} (astep st).

Notation " t '/' st '==>a*' t' " := (amultistep st t t') (at level 40, st at level 39).

Example astep_example1 : (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state ==>a× (ANum 15).

Proof.

apply multi_step with (APlus (ANum 3) (ANum 12)).

apply AS_Plus2.

apply av_num.

apply AS_Mult.

apply multi_step with (ANum 15).

apply AS_Plus.

apply multi_refl.

Qed.
```

We repeatedly applied *multi_step* until we got to a normal form. The proofs that the intermediate steps are possible are simple enough that auto, with appropriate hints, can solve them.

```
Hint Constructors astep aval.
Example astep_example1':
   (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state
   ==>a× (ANum 15).
Proof.
   eapply multi_step. auto. simpl.
   eapply multi_step. auto. simpl.
   apply multi_refl.
Qed.
```

The following custom Tactic Notation definition captures this pattern. In addition, before each *multi_step* we print out the current goal, so that the user can follow how the term is being evaluated.

```
Tactic Notation "print_goal" := match goal with \vdash ?x \Rightarrow idtac \ x \ end.
Tactic Notation "normalize" :=
   repeat (print_goal; eapply multi_step;
              [(eauto 10; fail) | (instantiate; simpl)]);
   apply multi_refl.
Example astep_example1":
  (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state
  ==>a\times (ANum 15).
Proof.
  normalize.
Qed.
   The normalize tactic also provides a simple way to calculate what the normal form of a
term is, by proving a goal with an existential variable in it.
Example astep_example1''' : \exists e',
  (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state
  ==>a\times e'.
Proof.
  eapply ex_intro. normalize.
Qed.
Exercise: 1 star (normalize_ex) Theorem normalize_ex: \exists e',
  (AMult (ANum 3) (AMult (ANum 2) (ANum 1))) / empty_state
  ==>a\times e'.
Proof.
   Admitted.
   Exercise: 1 star, optional (normalize_ex') This time prove it by using apply instead
of eapply.
Theorem normalize_ex': \exists e',
  (AMult (ANum 3) (AMult (ANum 2) (ANum 1))) / empty_state
  ==>a\times e'.
Proof.
   Admitted.
```

20.3 Typed Arithmetic Expressions

To motivate the discussion of type systems, let's begin as usual with an extremely simple toy language. We want it to have the potential for programs "going wrong" because of runtime type errors, so we need something a tiny bit more complex than the language of constants and addition that we used in chapter *Smallstep*: a single kind of data (just numbers) is too simple, but just two kinds (numbers and booleans) already gives us enough material to tell an interesting story.

The language definition is completely routine. The only thing to notice is that we are *not* using the asnum/aslist trick that we used in chapter ImpList to make all the operations total by forcibly coercing the arguments to + (for example) into numbers. Instead, we simply let terms get stuck if they try to use an operator with the wrong kind of operands: the step relation doesn't relate them to anything.

20.3.1 Syntax

```
Informally: t := true \mid false \mid if t then t else t \mid 0 \mid succ t \mid pred t \mid iszero t Formally:
Inductive tm : Type :=
    ttrue: tm
    tfalse : tm
    \mathsf{tif}: \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}
    tzero: tm
    tsucc: tm \rightarrow tm
    tpred : tm \rightarrow tm
    tiszero : tm \rightarrow tm.
    Values are true, false, and numeric values...
Inductive bvalue: tm \rightarrow Prop :=
    bv_true : bvalue ttrue
    bv_false : bvalue tfalse.
Inductive nvalue: tm \rightarrow Prop :=
    nv_zero : nvalue tzero
   | nv_succ : \forall t, nvalue t \rightarrow nvalue (tsucc t).
Definition value (t:tm) := bvalue \ t \lor nvalue \ t.
Hint Constructors bvalue nvalue.
Hint Unfold value.
```

20.3.2 Operational Semantics

Informally:

```
(ST_IfTrue) if true then t1 else t2 ==> t1
```

```
(ST_IfFalse) if false then t1 else t2 ==> t2
   t1 ==> t1'
(ST_If) if t1 then t2 else t3 ==> if t1' then t2 else t3
   t1 ==> t1'
(ST\_Succ) succ t1 ==> succ t1'
(ST_PredZero) \text{ pred } 0 ==> 0
   numeric value v1
(ST_PredSucc) pred (succ v1) ==> v1
   t1 ==> t1'
(ST\_Pred) pred t1 ==> pred t1'
(ST_IszeroZero) iszero 0 ==> true
   numeric value v1
(ST_IszeroSucc) iszero (succ v1) ==> false
   t1 ==> t1'
(ST_Iszero) iszero t1 ==> iszero t1' Formally:
Reserved Notation "t1'==>' t2" (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  \mid \mathsf{ST\_IfTrue} : \forall t1 \ t2,
       (tif ttrue t1 t2) ==> t1
  | ST_IfFalse : \forall t1 t2,
       (tif tfalse t1 t2) ==> t2
  | ST_If : \forall t1 t1' t2 t3,
       t1 ==> t1' \rightarrow
       (tif t1 t2 t3) ==> (tif t1' t2 t3)
  | ST_Succ : \forall t1 t1',
       t1 ==> t1' \rightarrow
       (tsucc t1) ==> (tsucc t1')
  | ST_PredZero :
       (tpred tzero) ==> tzero
  | ST_PredSucc : \forall t1,
       nvalue t1 \rightarrow
       (tpred (tsucc t1)) ==> t1
  | ST_Pred : \forall t1 t1',
```

```
t1 ==> t1' \rightarrow
       (tpred t1) ==> (tpred t1')
  | ST_IszeroZero :
       (tiszero tzero) ==> ttrue
  | ST_IszeroSucc : \forall t1,
        nvalue t1 \rightarrow
       (tiszero (tsucc t1)) ==> tfalse
  | ST_Iszero : \forall t1 t1',
       t1 ==> t1' \rightarrow
       (tiszero t1) ==> (tiszero t1')
where "t1 '==>' t2" := (step t1 \ t2).
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first:
  [ Case_aux c "ST_IfTrue" | Case_aux c "ST_IfFalse" | Case_aux c "ST_If"
   Case_aux c "ST_Succ" | Case_aux c "ST_PredZero"
   Case_aux c "ST_PredSucc" | Case_aux c "ST_Pred"
   Case_aux c "ST_IszeroZero" | Case_aux c "ST_IszeroSucc"
   Case\_aux \ c "ST_Iszero"].
```

Hint Constructors step.

Notice that the *step* relation doesn't care about whether expressions make global sense – it just checks that the operation in the *next* reduction step is being applied to the right kinds of operands. For example, the term *succ true* (i.e., *tsucc ttrue* in the formal syntax) cannot take a step, but the almost-as-obviously-nonsensical term succ (if true then true else true) can take *one* step.

20.3.3 Normal Forms and Values

The first interesting thing about the *step* relation in this language is that the strong progress theorem from the Smallstep chapter fails! That is, there are terms that are normal forms (they can't take a step) but not values (because we have not included them in our definition of possible "results of evaluation"). Such terms are *stuck*.

```
Notation step_normal_form := (normal_form step).

Definition stuck (t:tm) : Prop := step_normal_form t ∧ ¬ value t.

Hint Unfold stuck.

Exercise: 2 stars (some_term_is_stuck) Example some_term_is_stuck : ∃ t, stuck t.

Proof.

Admitted.
```

However, although values and normal forms are not the same in this language, the former set is included in the latter. This is important because it shows we did not accidentally define things so that some value could still take a step.

Exercise: 3 stars, optional (value_is_nf) Hint: You will reach a point in this proof where you need to use an induction to reason about a term that is known to be a numeric value. This induction can be performed either over the term itself or over the evidence that it is a numeric value. The proof goes through in either case, but you will find that one way is quite a bit shorter than the other. For the sake of the exercise, try to complete the proof both ways.

Exercise: 3 stars, optional (step_deterministic) Using $value_is_nf$, we can show that the step relation is also deterministic...

```
Theorem step_deterministic:
    deterministic step.

Proof with eauto.

Admitted.
```

20.3.4 Typing

The next critical observation about this language is that, although there are stuck terms, they are all "nonsensical", mixing booleans and numbers in a way that we don't even want to have a meaning. We can easily exclude such ill-typed terms by defining a typing relation that relates terms to the types (either numeric or boolean) of their final results.

```
Inductive ty : Type :=
     | TBool : ty
     | TNat : ty.
```

In informal notation, the typing relation is often written $\vdash t : T$, pronounced "t has type T." The \vdash symbol is called a "turnstile". (Below, we're going to see richer typing relations where an additional "context" argument is written to the left of the turnstile. Here, the context is always empty.)

```
(T_True) |- true : Bool
```

```
(T_False) |- false : Bool
    |- t1 : Bool |- t2 : T |- t3 : T
(T_If) |- if t1 then t2 else t3 : T
(T_Zero) \mid -0 : Nat
    |- t1 : Nat
(T\_Succ) |- succ t1 : Nat
    |- t1 : Nat
(T_Pred) |- pred t1 : Nat
    |- t1 : Nat
(T_IsZero) |- iszero t1 : Bool
Inductive has_type : tm \rightarrow ty \rightarrow Prop :=
   |\mathsf{T}_{\mathsf{L}}\mathsf{True}|:
          has_type ttrue TBool
  | T_False :
          has_type tfalse TBool
  \mid \mathsf{T}_{\mathsf{-}}\mathsf{lf} : \forall t1 \ t2 \ t3 \ T,
          has_type t1 TBool \rightarrow
          has_type t2 T \rightarrow
          has_type t3 \ T \rightarrow
          has_type (tif t1 \ t2 \ t3) T
  \mid \mathsf{T}_{\mathsf{-}}\mathsf{Zero} :
          has_type tzero TNat
  | \mathsf{T_-Succ} : \forall t1,
          has_type t1 TNat \rightarrow
          has_type (tsucc t1) TNat
  | \mathsf{T}_{\mathsf{P}}\mathsf{red} : \forall t1,
          has_type t1 TNat \rightarrow
          has\_type (tpred t1) TNat
  |\mathsf{T_Iszero}: \forall t1,
          has_type t1 TNat \rightarrow
          has_type (tiszero t1) TBool.
Tactic Notation "has_type_cases" tactic(first) ident(c) :=
  first;
  [ Case_aux c "T_True" | Case_aux c "T_False" | Case_aux c "T_If"
    Case_aux c "T_Zero" | Case_aux c "T_Succ" | Case_aux c "T_Pred"
   | Case\_aux \ c \ "T\_Iszero" |.
```

Hint Constructors has_type.

Examples

It's important to realize that the typing relation is a *conservative* (or *static*) approximation: it does not calculate the type of the normal form of a term.

```
Example has_type_1:
 has_type (tif tfalse tzero (tsucc tzero)) TNat.
Proof.
 apply T_lf.
   apply T_False.
   apply T_Zero.
   apply T_Succ.
     apply T_Zero.
Qed.
   (Since we've included all the constructors of the typing relation in the hint database, the
auto tactic can actually find this proof automatically.)
Example has_type_not :
 ¬ has_type (tif tfalse tzero ttrue) TBool.
Proof.
 intros Contra. solve by inversion 2. Qed.
has\_type (tsucc t) TNat \rightarrow
 has_type t TNat.
Proof.
  Admitted.
```

20.3.5 Progress

The typing relation enjoys two critical properties. The first is that well-typed normal forms are values (i.e., not stuck).

Exercise: 3 stars, recommended (finish_progress_informal) Complete the following proof:

```
Theorem: If \vdash t : T, then either t is a value or else t ==> t' for some t'. Proof: By induction on a derivation of \vdash t : T.
```

• If the last rule in the derivation is $T_{-}If$, then $t = \texttt{if}\ t1$ then t2 else t3, with $\vdash t1$: Bool, $\vdash t2$: T and $\vdash t3$: T. By the IH, either t1 is a value or else t1 can step to some t1.

- If t1 is a value, then it is either an *nvalue* or a *bvalue*. But it cannot be an *nvalue*, because we know $\vdash t1 : Bool$ and there are no rules assigning type Bool to any term that could be an *nvalue*. So t1 is a bvalue i.e., it is either true or false. If t1 = true, then t steps to t2 by ST_IfTrue , while if t1 = false, then t steps to t3 by $ST_IfFalse$. Either way, t can step, which is what we wanted to show.
- If t1 itself can take a step, then, by $ST_{-}If$, so can t.

```
Exercise: 3 stars (finish_progress) Theorem progress: \forall t T,
  has_type t T \rightarrow
  value t \vee \exists t', t ==> t'.
Proof with auto.
  intros t T HT.
  has_type_cases (induction HT) Case...
  Case "T_If".
    right. inversion IHHT1; clear IHHT1.
    SCase "t1 is a value". inversion H; clear H.
       SSCase "t1 is a bvalue". inversion H0; clear H0.
         SSSCase "t1 is ttrue".
           ∃ t2...
         SSSCase "t1 is tfalse".
           ∃ t3...
       SSCase "t1 is an nvalue".
         solve by inversion 2.
                                      SCase "t1 can take a step".
       inversion H as [t1' H1].
       \exists (tif t1' t2 t3)...
   Admitted.
```

This is more interesting than the strong progress theorem that we saw in the Smallstep chapter, where *all* normal forms were values. Here, a term can be stuck, but only if it is ill typed.

Exercise: 1 star (step_review) Quick review. Answer true or false. In this language...

- Every well-typed normal form is a value.
- Every value is a normal form.
- The single-step evaluation relation is a partial function (i.e., it is deterministic).
- The single-step evaluation relation is a *total* function.

20.3.6 Type Preservation

The second critical property of typing is that, when a well-typed term takes a step, the result is also a well-typed term.

This theorem is often called the *subject reduction* property, because it tells us what happens when the "subject" of the typing relation is reduced. This terminology comes from thinking of typing statements as sentences, where the term is the subject and the type is the predicate.

Exercise: 3 stars, recommended (finish_preservation_informal) Complete the following proof:

```
Theorem: If \vdash t : T and t ==> t', then \vdash t' : T.
Proof: By induction on a derivation of \vdash t : T.
```

• If the last rule in the derivation is $T_{-}If$, then t = if t1 then t2 else t3, with $\vdash t1 : Bool$, $\vdash t2 : T$ and $\vdash t3 : T$.

Inspecting the rules for the small-step reduction relation and remembering that t has the form if ..., we see that the only ones that could have been used to prove t ==> t are ST_IfTrue , $ST_IfFalse$, or ST_If .

- If the last rule was $ST_{-}IfTrue$, then t'=t2. But we know that $\vdash t2:T$, so we are done.
- If the last rule was $ST_IfFalse$, then t'=t3. But we know that $\vdash t3:T$, so we are done.
- If the last rule was ST_If , then t' = if t1' then t2 else t3, where t1 ==> t1'. We know $\vdash t1 : Bool$ so, by the IH, $\vdash t1' : Bool$. The T_If rule then gives us \vdash if t1' then t2 else t3 : T, as required.

```
Exercise: 2 stars (finish_preservation) Theorem preservation : \forall \ t \ t' \ T, has_type t \ T \rightarrow t => t' \rightarrow has_type t' \ T.

Proof with auto.
intros t \ t' \ T \ HT \ HE.
generalize dependent t'.
has_type_cases (induction HT) Case;

intros t' \ HE;

try (solve by inversion).
```

```
Case "T_If". inversion HE; subst.

SCase "ST_IFTrue". assumption.

SCase "ST_IfFalse". assumption.

SCase "ST_If". apply T_If; try assumption.

apply IHHT1; assumption.

Admitted.

□
```

Exercise: 3 stars (preservation_alternate_proof) Now prove the same property again by induction on the *evaluation* derivation instead of on the typing derivation. Begin by carefully reading and thinking about the first few lines of the above proof to make sure you understand what each one is doing. The set-up for this proof is similar, but not exactly the same.

```
Theorem preservation': \forall \ t \ t' T, has_type t \ T \rightarrow t ==> t' \rightarrow has_type t' T.

Proof with eauto.

Admitted.
```

20.3.7 Type Soundness

Putting progress and preservation together, we can see that a well-typed term can *never* reach a stuck state.

```
Definition multistep := (multi step). Notation "t1'==>*' t2" := (multistep t1\ t2) (at level 40). Corollary soundness : \forall\ t\ t' T, has_type t\ T\to t=>*\ t'\to \infty (stuck t'). Proof. intros t\ t' T HT\ P. induction P; intros [R\ S]. destruct (progress x\ T\ HT); auto. apply IHP. apply (preservation x\ y\ T\ HT\ H). unfold stuck. split; auto. Qed.
```

20.3.8 Additional Exercises

Exercise: 2 stars, recommended (subject_expansion) Having seen the subject reduction property, it is reasonable to wonder whether the opposity property – subject expansion – also holds. That is, is it always the case that, if t ==> t' and $has_type\ t'$ T, then

has_type t T? If so, prove it. If not, give a counter-example. (You do not need to prove your counter-example in Coq, but feel free to do so if you like.) Exercise: 2 stars (variation1) Suppose we add the following two new rules to the reduction relation: | ST_PredTrue : (tpred ttrue) ==> (tpred tfalse) | ST_PredFalse : (tpred tfalse) ==> (tpred ttrue) Which of the following properties remain true in the presence of these rules? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample. • Determinism of step • Progress • Preservation Exercise: 2 stars (variation2) Suppose, instead, that we add this new rule to the typing relation: | T_IfFunny : forall t2 t3, has_type t2 TNat -> has_type (tif ttrue t2 t3) TNat Which of the following properties remain true in the presence of this rule? (Answer in the same style as above.) • Determinism of step Progress • Preservation Exercise: 2 stars (variation3) Suppose, instead, that we add this new rule to the typing relation: | T_SuccBool: forall t, has_type t TBool -> has_type (tsucc t) TBool Which of the following properties remain true in the presence of this rule? (Answer in the same style as above.) • Determinism of step • Progress

• Preservation

Exercise: 2 stars (variation4) Suppose, instead, that we add this new rule to the <i>step</i> relation: $ ST_Funny1 :$ for all t2 t3, (tif ttrue t2 t3) ==> t3 Which of the above properties become false in the presence of this rule? For each one that does, give a counter-example.
Exercise: 2 stars (variation5) Suppose instead that we add this rule: $ ST_Funny2 :$ for all t1 t2 t2' t3, t2 ==> t2' -> (tif t1 t2 t3) ==> (tif t1 t2' t3) Which of the above properties become false in the presence of this rule? For each one that does, give a counterexample.
Exercise: 2 stars (variation6) Suppose instead that we add this rule: ST_Funny3 : (tpred tfalse) ==> (tpred (tpred tfalse)) Which of the above properties become false in the presence of this rule? For each one that does, give a counter-example.
Exercise: 2 stars (variation7) Suppose instead that we add this rule: T_Funny4 : has_type tzero TBool]] Which of the above properties become false in the presence of this rule? For each one that does, give a counter-example.
Exercise: 2 stars (variation8) Suppose instead that we add this rule: T_Funny5 : has_type (tpred tzero) TBool]] Which of the above properties become false in the presence of this rule? For each one that does, give a counter-example.
Exercise: 3 stars, optional (more_variations) Make up some exercises of your own along the same lines as the ones above. Try to find ways of selectively breaking properties – i.e., ways of changing the definitions that break just one of the properties and leave the others alone. \Box
Exercise: 1 star (remove_predzero) The evaluation rule $E_PredZero$ is a bit counterintuitive: we might feel that it makes more sense for the predecessor of zero to be undefined, rather than being defined to be zero. Can we achieve this simply by removing the rule from the definition of $step$? Would doing so create any problems elsewhere?
Exercise: 4 stars, optional (prog_pres_bigstep) Suppose our evaluation relation is defined in the big-step style. What are the appropriate analogs of the progress and preservation properties?

Chapter 21

Library Stlc

21.1 Stlc: The Simply Typed Lambda-Calculus

Require Export Types.

21.2 The Simply Typed Lambda-Calculus

The simply typed lambda-calculus (STLC) is a tiny core calculus embodying the key concept of *functional abstraction*, which shows up in pretty much every real-world programming language in some form (functions, procedures, methods, etc.).

We will follow exactly the same pattern as in the previous chapter when formalizing this calculus (syntax, small-step semantics, typing rules) and its main properties (progress and preservation). The new technical challenges (which will take some work to deal with) all arise from the mechanisms of *variable binding* and *substitution*.

21.2.1 Overview

The STLC is built on some collection of base types – booleans, numbers, strings, etc. The exact choice of base types doesn't matter – the construction of the language and its theoretical properties work out pretty much the same – so for the sake of brevity let's take just Bool for the moment. At the end of the chapter we'll see how to add more base types, and in later chapters we'll enrich the pure STLC with other useful constructs like pairs, records, subtyping, and mutable state.

Starting from the booleans, we add three things:

- variables
- function abstractions
- application

This gives us the following collection of abstract syntax constructors (written out here in informal BNF notation – we'll formalize it below).

Informal concrete syntax:

t	::=	х	variable
		\x:T.t1	abstraction
		t1 t2	application
		true	constant true
		false	constant false
	- 1	if t1 then t2 else t3	conditional

The \setminus symbol in a function abstraction $\setminus x: T.t1$ is often written as a greek "lambda" (hence the name of the calculus). The variable x is called the *parameter* to the function; the term t1 is its body. The annotation :T specifies the type of arguments that the function can be applied to.

Some examples:

- $\xspace \xspace \x$
 - The identity function for booleans.
- $(\x:Bool.\ x)\ true$

The identity function for booleans, applied to the boolean true.

• $\xspace \xspace \x$

The boolean "not" function.

• $\xspace \xspace \x$

The constant function that takes every (boolean) argument to true.

• $\xrack x:Bool. \y:Bool. \xrack x$

A two-argument function that takes two booleans and returns the first one. (Note that, as in Coq, a two-argument function is really a one-argument function whose body is also a one-argument function.)

• $(\xspace x:Bool.\\yspace y:Bool.\\xspace x)$ false true

A two-argument function that takes two booleans and returns the first one, applied to the booleans *false* and *true*. Note that, as in Coq, application associates to the left – i.e., this expression is parsed as $((\xspace x:Bool.\xspace x):Bool.\xspace x)$ false) true.

• $\fint f:Bool \rightarrow Bool. \ f \ (f \ true)$

A higher-order function that takes a function f (from booleans to booleans) as an argument, applies f to true, and applies f again to the result.

• $(\frac{f:Bool}{\rightarrow}Bool.\ f\ (f\ true))\ (\x:Bool.\ false)$

The same higher-order function, applied to the constantly false function.

As the last several examples show, the STLC is a language of *higher-order* functions: we can write down functions that take other functions as arguments and/or return other functions as results.

Another point to note is that the STLC doesn't provide any primitive syntax for defining named functions – all functions are "anonymous." We'll see in chapter MoreStlc that it is easy to add named functions to what we've got – indeed, the fundamental naming and binding mechanisms are exactly the same.

The types of the STLC include Bool, which classifies the boolean constants true and false as well as more complex computations that yield booleans, plus arrow types that classify functions.

```
T ::= Bool
| T1 -> T2
```

For example:

- $\xspace \xspace \x$
- $\xspace \xspace \x$
- $(\xspace x:Bool.\xspace x)$ true has type $Bool.\xspace$
- $\xspace \xspace \x$
- $(\xspace x:Bool.\\yspace y:Bool.\\xspace x)$ false has type $Bool \rightarrow Bool$
- $(\x:Bool.\\y:Bool.\ x)$ false true has type Bool
- $\final f:Bool \to Bool. f (f true) has type (Bool \to Bool) \to Bool$
- $(\frac{f:Bool}{\rightarrow}Bool.\ f\ (f\ true))\ (\x:Bool.\ false)$ has type Bool

21.2.2 Syntax

Module STLC.

Types

```
\begin{array}{l} \texttt{Inductive } \ \textbf{ty} : \ \texttt{Type} := \\ | \ \mathsf{TBool} : \ \textbf{ty} \\ | \ \mathsf{TArrow} : \ \textbf{ty} \to \textbf{ty} \to \textbf{ty}. \end{array}
```

Terms

```
Inductive tm: Type :=  | tvar: id \rightarrow tm | tapp: tm \rightarrow tm \rightarrow tm | tabs: id \rightarrow ty \rightarrow tm \rightarrow tm | ttrue: tm | tfalse: tm | tif: tm \rightarrow tm \rightarrow tm.

Tactic Notation "t_cases" tactic(first) \ ident(c) := first; [ Case\_aux \ c "tvar" | Case\_aux \ c "tapp" | Case\_aux \ c "tabs" | Case\_aux \ c "ttrue" | Case\_aux \ c "tfalse" | Case\_aux \ c "tif" ].
```

Note that an abstraction $\ x:T.t$ (formally, $tabs\ x\ T\ t$) is always annotated with the type T of its parameter, in contrast to Coq (and other functional languages like ML, Haskell, etc.), which use $type\ inference$ to fill in missing annotations. We're not considering type inference here, to keep things simple.

Some examples...

```
Definition x := (Id 0).
Definition y := (Id 1).
Definition z := (Id 2).
Hint Unfold x.
Hint Unfold y.
Hint Unfold z.
   idB = \langle x:Bool. \ x \rangle
Notation idB :=
  (tabs \times TBool (tvar \times)).
    idBB = \x:Bool \rightarrow Bool. \ x
Notation idBB :=
  (tabs x (TArrow TBool TBool) (tvar x)).
   idBBBB = \langle x:(Bool \rightarrow Bool) - \rangle (Bool \rightarrow Bool). \ x
Notation idBBBB :=
  (tabs x (TArrow (TArrow TBool TBool)
                            (TArrow TBool TBool))
     (tvar x)).
   k = \x:Bool. \y:Bool. \x
Notation k := (tabs \times TBool (tabs y TBool (tvar x))).
    (We write these as Notations rather than Definitions to make things easier for auto.)
```

21.2.3 Operational Semantics

To define the small-step semantics of STLC terms, we begin – as always – by defining the set of values. Next, we define the critical notions of *free variables* and *substitution*, which are used in the reduction rule for application expressions. And finally we give the small-step relation itself.

Values

To define the values of the STLC, we have a few cases to consider.

First, for the boolean part of the language, the situation is clear: *true* and *false* are the only values. (An if expression is never a value.)

Second, an application is clearly not a value: It represents a function being invoked on some argument, which clearly still has work left to do.

Third, for abstractions, we have a choice:

- We can say that $\xspace x: T.t1$ is a value only when t1 is a value i.e., only if the function's body has been reduced (as much as it can be without knowing what argument it is going to be applied to).
- Or we can say that $\xspace x: T.t1$ is always a value, no matter whether t1 is one or not in other words, we can say that reduction stops at abstractions.

Coq (in its built-in functional programming langauge) makes the first choice – for example, Eval simpl in (fun x:bool => 3 + 4) yields $fun x:bool \Rightarrow 7$. But most real-world functional programming languages make the second choice – reduction of a function's body only begins when the function is actually applied to an argument. We also make the second choice here.

Finally, having made the choice not to reduce under abstractions, we don't need to worry about whether variables are values, since we'll always be reducing programs "from the outside in," and that means the *step* relation will always be working with closed terms (ones with no free variables).

```
Inductive value : tm \rightarrow Prop := |v_abs : \forall x \ T \ t,
value (tabs x \ T \ t)
| t_true :
value ttrue
| t_false :
value tfalse.
```

Hint Constructors value.

Free Variables and Substitution

Now we come to the heart of the matter: the operation of substituting one term for a variable in another term.

This operation will be used below to define the operational semantics of function application, where we will need to substitute the argument term for the function parameter in the function's body. For example, we reduce (\x :Bool. if x then true else x) false to false by substituting false for the parameter x in the body of the function. In general, we need to be able to substitute some given term s for occurrences of some variable x in another term t. In informal discussions, this is usually written [x:=s]t and pronounced "substitute x with s in t."

Here are some examples:

```
x:=true \ (if \ x \ then \ x \ else \ false) yields if true \ then \ true \ else \ false
x:=true \ x \ yields \ true
x:=true \ (if \ x \ then \ x \ else \ y) yields if true \ then \ true \ else \ y
x:=true \ y \ yields \ y
x:=true \ false \ yields \ false \ (vacuous \ substitution)
x:=true \ (\ y:Bool. \ if \ y \ then \ x \ else \ false) yields \ y:Bool. \ if \ y \ then \ true \ else \ false
x:=true \ (\ y:Bool. \ x) yields \ y:Bool. \ y
x:=true \ (\ x:Bool. \ x) yields \ y:Bool. \ x
```

The last example is very important: substituting x with true in $\xspace x:Bool.$ x does not yield $\xspace x:Bool.$ true! The reason for this is that the x in the body of $\xspace x:Bool.$ x is bound by the abstraction: it is a new, local name that just happens to be spelled the same as some global name x.

```
Here is the definition, informally... x:=sx=s x:=sy=y if x <> y x:=s(\x:T11.t12) = \x:T11. t12 x:=s(\y:T11.t12) = \y:T11. x:=st12 if x <> y x:=s(t1 t2) = (x:=st1) (x:=st2) x:=strue = true x:=sfalse = false x:=s(if t1 then t2 else t3) = if <math>x:=st1 then x:=st2 else x:=st3 ]] ... and formally:
```

```
Fixpoint subst (x:\operatorname{id}) (s:\operatorname{tm}) (t:\operatorname{tm}) : \operatorname{tm} := \max t t with |\operatorname{tvar} x' \Rightarrow \inf \operatorname{beq\_id} x \ x' then s else t |\operatorname{tabs} x' \ T \ t1 \Rightarrow \inf \operatorname{tabs} x' \ T \ (\operatorname{if} \operatorname{beq\_id} x \ x' \ \operatorname{then} \ t1 \ \operatorname{else} \ (\operatorname{subst} x \ s \ t1)) |\operatorname{tapp} \ t1 \ t2 \Rightarrow
```

```
tapp (subst x \ s \ t2) | ttrue \Rightarrow ttrue | tfalse \Rightarrow tfalse | tif t1 \ t2 \ t3 \Rightarrow tif (subst x \ s \ t1) (subst x \ s \ t2) (subst x \ s \ t3) end.

Notation "'[' x ':=' s ']' t" := (subst x \ s \ t) (at level 20).
```

Technical note: Substitution becomes trickier to define if we consider the case where s, the term being substituted for a variable in some other term, may itself contain free variables. Since we are only interested here in defining the step relation on closed terms (i.e., terms like $\xspace x:Bool.$ x y that mention variables are not bound by some enclosing lambda), we can avoid this extra complexity here.

Reduction

The small-step reduction relation for STLC now follows the same pattern as the ones we have seen before. Intuitively, to reduce a function application, we first reduce its left-hand side until it becomes a literal function; then we reduce its right-hand side (the argument) until it is also a value; and finally we substitute the argument for the bound variable in the body of the function. This last rule, written informally as (x:T:t12) v2 ==> x:=v2t12 is traditionally called "beta-reduction".

value v2

```
(ST\_AppAbs) \ (\x:T.t12) \ v2 ==> x:=v2t12 t1 ==> t1' (ST\_App1) \ t1 \ t2 ==> t1' \ t2 value \ v1 \ t2 ==> t2' (ST\_App2) \ v1 \ t2 ==> v1 \ t2' \ ... \ plus \ the \ usual \ rules \ for \ booleans: (ST\_IfTrue) \ (if \ true \ then \ t1 \ else \ t2) ==> t1 (ST\_IfFalse) \ (if \ false \ then \ t1 \ else \ t2) ==> t2 t1 ==> t1' (ST\_If) \ (if \ t1 \ then \ t2 \ else \ t3) ==> (if \ t1' \ then \ t2 \ else \ t3) Reserved \ Notation \ "t1' ==>' t2" \ (at \ level \ 40). Inductive \ step: \ tm \to tm \to Prop:= |\ ST\_AppAbs: \ \forall \ x \ T \ t12 \ v2,
```

```
value v2 \rightarrow
           (tapp (tabs x \ T \ t12) \ v2) ==> [x:=v2] \ t12
  | ST\_App1 : \forall t1 t1' t2,
          t1 \Longrightarrow t1' \rightarrow
          tapp t1 t2 ==> tapp <math>t1, t2
  | ST\_App2 : \forall v1 t2 t2',
          value v1 \rightarrow
          t2 ==> t2' \rightarrow
          tapp v1 t2 ==> tapp <math>v1 t2'
  \mid ST_{-}IfTrue : \forall t1 t2,
       (tif ttrue t1 t2) ==> t1
  | ST_IfFalse : \forall t1 t2,
       (tif tfalse t1 t2) ==> t2
  | ST_If : ∀ t1 t1' t2 t3,
       t1 ==> t1' \rightarrow
       (tif t1 t2 t3) ==> (tif t1' t2 t3)
where "t1 '==>' t2" := (step t1 \ t2).
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first;
   Case_aux c "ST_AppAbs" | Case_aux c "ST_App1"
   Case_aux c "ST_App2" | Case_aux c "ST_IfTrue"
  | Case_aux c "ST_IfFalse" | Case_aux c "ST_If" ].
Hint Constructors step.
Notation multistep := (multi step).
Notation "t1'==>*' t2" := (multistep t1 t2) (at level 40).
Examples
Example: ((x:Bool->Bool. x) (x:Bool. x)) ==>* (x:Bool. x) i.e. (idBB idB) ==>*
idB
Lemma step_example1:
  (tapp idBB idB) ==>* idB.
Proof.
  eapply multi_step.
     apply ST_AppAbs.
     apply v_abs.
  simpl.
  apply multi_refl. Qed.
   A more automatic proof
Lemma step_example1':
```

```
(tapp idBB idB) ==>* idB.
Proof. normalize. Qed.
Lemma step_example2 :
  (tapp idBB (tapp idBB idB)) ==>* idB.
Proof.
  eapply multi_step.
    apply ST_App2. auto.
    apply ST_AppAbs. auto.
  eapply multi_step.
    apply ST_AppAbs. simpl. auto.
  simpl. apply multi_refl. Qed.
   Again, we can use the normalize tactic from above to simplify the proof.
Lemma step_example2':
  (tapp idBB (tapp idBB idB)) ==>* idB.
Proof.
  normalize.
Qed.
Exercise: 2 stars (step_example3) Try to do this one both with and without normal-
ize.
Lemma step_example3:
        (tapp (tapp idBBBB idBB) idB)
  ==>* idB.
Proof.
   Admitted.
```

21.2.4 Typing

Contexts

Question: What is the type of the term "x y"?

Answer: It depends on the types of x and y!

I.e., in order to assign a type to a term, we need to know what assumptions we should make about the types of its free variables.

This leads us to a three-place "typing judgment", informally written $Gamma \vdash t : T$, where Gamma is a "typing context" – a mapping from variables to their types.

We hide the definition of partial maps in a module since it is actually defined in SfLib.

Module PartialMap.

Definition partial_map $(A:Type) := id \rightarrow option A.$

```
Informally, we'll write Gamma, x:T for "extend the partial function Gamma to also map
x to T." Formally, we use the function extend to add a binding to a partial map.
Definition extend \{A: \mathsf{Type}\}\ (Gamma: \mathsf{partial\_map}\ A)\ (x:\mathsf{id})\ (T:A):=
  fun x' \Rightarrow \text{if beq\_id } x \ x' \text{ then } \text{Some } T \text{ else } Gamma \ x'.
Lemma extend_eq : \forall A (ctxt: partial_map A) x T,
  (extend ctxt \ x \ T) x = Some T.
Proof.
  intros. unfold extend. rewrite ← beq_id_refl. auto.
Lemma extend_neq : \forall A (ctxt: partial_map A) x1 T x2,
  beq_id x2 \ x1 = false \rightarrow
  (extend ctxt \ x2 \ T) x1 = ctxt \ x1.
Proof.
  intros. unfold extend. rewrite H. auto.
Qed.
End PARTIALMAP.
Definition context := partial_map ty.
Typing Relation
Gamma \ x = T

Hint Constructors has_type.
Examples
Example typing_example_1:
  has_type empty (tabs x TBool (tvar x)) (TArrow TBool TBool).
  apply T_Abs. apply T_Var. reflexivity. Qed.
   Note that since we added the has_type constructors to the hints database, auto can
actually solve this one immediately.
Example typing_example_1':
  has_type empty (tabs x TBool (tvar x)) (TArrow TBool TBool).
Proof. auto. Qed.
Hint Unfold beq_id beq_nat extend.
   Another example: empty |-\rangle x:A. \ y:A->A. \ y(yx) : A->(A->A)->A.
Example typing_example_2:
  has_type empty
     (tabs x TBool
        (tabs y (TArrow TBool TBool)
            (tapp (tvar y) (tapp (tvar y) (tvar x)))))
```

```
(TArrow TBool (TArrow (TArrow TBool TBool)).
Proof with auto using extend_eq.
  apply T_Abs.
  apply T_Abs.
  eapply T_App. apply T_Var...
  eapply T_App. apply T_Var...
  apply T_Var...
Qed.
Exercise: 2 stars, optional (typing_example_2_full) Prove the same result without
using auto, eauto, or eapply.
Example typing_example_2_full:
  has_type empty
    (tabs x TBool
       (tabs y (TArrow TBool TBool)
           (tapp (tvar y) (tapp (tvar y) (tvar x)))))
    (TArrow TBool (TArrow (TArrow TBool TBool)).
Proof.
   Admitted.
   Exercise: 2 stars (typing_example_3) Formally prove the following typing derivation
holds:
   empty |-(x:Bool->B. y:Bool->Bool. z:Bool. y (x z)) : T.
Example typing_example_3 :
  \exists T,
    has_type empty
      (tabs x (TArrow TBool TBool)
          (tabs y (TArrow TBool TBool)
             (tabs z TBool
                (tapp (tvar y) (tapp (tvar x) (tvar z)))))
      T
Proof with auto.
   Admitted.
   We can also show that terms are not typable. For example, let's formally check that
there is no typing derivation assigning a type to the term \xspace x:Bool. \y:Bool, \xspace y=i.e., \xspace
exists T, empty |-(x:Bool, y:Bool, x, y)| : T.
Example typing_nonexample_1:
  \neg \exists T,
      has_type empty
```

```
(tabs x TBool
             (tabs y TBool
                (tapp (tvar x) (tvar y))))
         T.
Proof.
  intros Hc. inversion Hc.
  inversion H. subst. clear H.
  inversion H5. subst. clear H5.
  inversion H_4. subst. clear H_4.
  inversion H2. subst. clear H2.
  inversion H5. subst. clear H5.
  inversion H1. Qed.
Exercise: 3 stars (typing_nonexample_3) Another nonexample: ~ (exists S, exists T,
empty |-(x:S. x x): T|.
Example typing_nonexample_3:
  \neg (\exists S, \exists T,
        has_type empty
           (tabs \times S
              (tapp (tvar x) (tvar x)))
           T).
Proof.
   Admitted.
```

Exercise: 1 star, optional (typing_statements) Which of the following propositions are provable?

```
• y:Bool \vdash \x:Bool.x : Bool \rightarrow Bool
```

•
$$\exists T, empty \vdash (\y:Bool \rightarrow Bool. \x:Bool. \y x) : T$$

•
$$\exists T, empty \vdash (\y:Bool \rightarrow Bool. \x:Bool. \x y) : T$$

•
$$\exists S, x:S \vdash (\y:Bool \rightarrow Bool. y) x: S$$

$$\bullet \exists S, \exists T, x:S \vdash (x x x) : T$$

Exercise: 1 star (more_typing_statements) Which of the following propositions are provable? For the ones that are, give witnesses for the existentially bound variables.

- $\exists T, empty \vdash (\x:A \rightarrow B, \y:B \rightarrow C, \z:A, y (x z)):T$
- $\exists S, \exists U, \exists T, x:S, y:U \vdash \exists X:A. x (y z) : T$
- $\exists S, \exists T, x:S \vdash \forall y:A. x (x y) : T$
- $\exists S, \exists U, \exists T, x:S \vdash x (\z:U.zx) : T$

21.2.5 Properties

Progress

The *progress* theorem tells us that closed, well-typed terms are not stuck: either a well-typed term is a value, or it can take an evaluation step.

```
Theorem progress: \forall t \ T,

has_type empty t \ T \rightarrow

value t \lor \exists t', t ==> t'.
```

Proof: by induction on the derivation of $\vdash t : T$.

- The last rule of the derivation cannot be $T_{-}Var$, since a variable is never well typed in an empty context.
- The T_True , T_False , and T_Abs cases are trivial, since in each of these cases we know immediately that t is a value.
- If the last rule of the derivation was T_-App , then t = t1 t2, and we know that t1 and t2 are also well typed in the empty context; in particular, there exists a type T2 such that $\vdash t1 : T2 \to T$ and $\vdash t2 : T2$. By the induction hypothesis, either t1 is a value or it can take an evaluation step.
 - If t1 is a value, we now consider t2, which by the other induction hypothesis must also either be a value or take an evaluation step.
 - * Suppose t2 is a value. Since t1 is a value with an arrow type, it must be a lambda abstraction; hence t1 t2 can take a step by ST_AppAbs .
 - * Otherwise, t2 can take a step, and hence so can t1 t2 by ST_App2 .
 - If t1 can take a step, then so can t1 t2 by ST_-App1 .
- If the last rule of the derivation was $T_{-}If$, then t = if t1 then t2 else t3, where t1 has type Bool. By the IH, t1 is either a value or takes a step.
 - If t1 is a value, then since it has type Bool it must be either true or false. If it is true, then t steps to t2; otherwise it steps to t3.

- Otherwise, t1 takes a step, and therefore so does t (by $ST_{-}If$).

```

```

Free Occurrences

A variable x appears free in a term t if t contains some occurrence of x that is not under an abstraction labeled x. For example:

- y appears free, but x does not, in $\xspace x: T \to U$. x y
- both x and y appear free in $(\x: T \to U. \ x \ y) \ x$
- no variables appear free in $\xspace x: T \to U$. $\xspace y: T$. $\xspace x: y: T$. $\xspace x: y: T$.

```
Inductive appears_free_in : id \rightarrow tm \rightarrow Prop :=
  \mid \mathsf{afi}_{\mathsf{var}} : \forall x,
        appears_free_in x (tvar x)
  | afi_app1 : \forall x t1 t2,

Hint Constructors appears_free_in.

A term in which no variables appear free is said to be *closed*.

```
Definition closed (t:tm) :=
  \forall x, \neg appears\_free\_in x t.
```

Substitution

We first need a technical lemma connecting free variables and typing contexts. If a variable x appears free in a term t, and if we know t is well typed in context Gamma, then it must be the case that Gamma assigns a type to x.

```
Lemma free_in_context : \forall x \ t \ T \ Gamma, appears_free_in x \ t \rightarrow has_type Gamma \ t \ T \rightarrow \exists \ T', Gamma \ x = Some \ T'.
```

Proof: We show, by induction on the proof that x appears free in t, that, for all contexts Gamma, if t is well typed under Gamma, then Gamma assigns some type to x.

- If the last rule used was $af_{-}var$, then t = x, and from the assumption that t is well typed under Gamma we have immediately that Gamma assigns a type to x.
- If the last rule used was afi_app1 , then t = t1 t2 and x appears free in t1. Since t is well typed under Gamma, we can see from the typing rules that t1 must also be, and the IH then tells us that Gamma assigns x a type.
- Almost all the other cases are similar: x appears free in a subterm of t, and since t is well typed under Gamma, we know the subterm of t in which x appears is well typed under Gamma as well, and the IH gives us exactly the conclusion we want.
- The only remaining case is aft_abs . In this case t = y:T11.t12, and x appears free in t12; we also know that x is different from y. The difference from the previous cases is that whereas t is well typed under Gamma, its body t12 is well typed under (Gamma, y:T11), so the IH allows us to conclude that x is assigned some type by the extended context (Gamma, y:T11). To conclude that Gamma assigns a type to x, we appeal to lemma $extend_neq$, noting that x and y are different variables.

Proof.

Next, we'll need the fact that any term t which is well typed in the empty context is closed – that is, it has no free variables.

Exercise: 2 stars (typable_empty__closed) Corollary typable_empty__closed : $\forall t$ T,

```
\begin{array}{ll} \mathbf{has\_type} \ \mathrm{empty} \ t \ T \rightarrow \\ \mathrm{closed} \ t. \end{array}
```

Proof.

Admitted.

Sometimes, when we have a proof $Gamma \vdash t : T$, we will need to replace Gamma by a different context Gamma. When is it safe to do this? Intuitively, it must at least be the case that Gamma assigns the same types as Gamma to all the variables that appear free in t. In fact, this is the only condition that is needed.

```
Lemma context_invariance : \forall Gamma Gamma' t T, has_type Gamma t T \rightarrow (\forall x, appears_free_in x t \rightarrow Gamma x = Gamma' x) \rightarrow has_type Gamma' t T.
```

Proof: By induction on the derivation of $Gamma \vdash t : T$.

- If the last rule in the derivation was $T_{-}Var$, then t=x and $Gamma\ x=T$. By assumption, $Gamma'\ x=T$ as well, and hence $Gamma' \vdash t:T$ by $T_{-}Var$.
- If the last rule was T_Abs , then $t = \y: T11$. t12, with $T = T11 \rightarrow T12$ and Gamma, $y: T11 \vdash t12 : T12$. The induction hypothesis is that for any context Gamma", if Gamma, y: T11 and Gamma" assign the same types to all the free variables in t12, then t12 has type T12 under Gamma". Let Gamma be a context which agrees with Gamma on the free variables in t; we must show Gamma $\vdash \y: T11$. $t12: T11 \rightarrow T12$.

By T_-Abs , it suffices to show that Gamma', $y:T11 \vdash t12:T12$. By the IH (setting Gamma'' = Gamma', y:T11), it suffices to show that Gamma, y:T11 and Gamma', y:T11 agree on all the variables that appear free in t12.

Any variable occurring free in t12 must either be y, or some other variable. Gamma, y:T11 and Gamma, y:T11 clearly agree on y. Otherwise, we note that any variable other than y which occurs free in t12 also occurs free in $t = \y:T11$. t12, and by assumption Gamma and Gamma agree on all such variables, and hence so do Gamma, y:T11 and Gamma, y:T11.

in t1 are also free in t1 t2, and similarly for free variables in t2; hence the desired result follows by the two IHs.

Proof with eauto.

Qed.

Now we come to the conceptual heart of the proof that reduction preserves types – namely, the observation that substitution preserves types.

Formally, the so-called Substitution Lemma says this: suppose we have a term t with a free variable x, and suppose we've been able to assign a type T to t under the assumption that x has some type U. Also, suppose that we have some other term v and that we've shown that v has type U. Then, since v satisfies the assumption we made about x when typing t, we should be able to substitute v for each of the occurrences of x in t and obtain a new term that still has type T.

```
 \begin{array}{l} \textit{Lemma} \colon \text{If } \textit{Gamma}, x \colon U \vdash t \colon \textit{T} \text{ and } \vdash v \colon \textit{U}, \text{ then } \textit{Gamma} \vdash [x \colon = v]t \colon \textit{T}. \\ \text{Lemma substitution\_preserves\_typing} \colon \forall \textit{Gamma} \ x \ \textit{U} \ t \ t' \ \textit{T}, \\ \text{has\_type (extend } \textit{Gamma} \ x \ \textit{U}) \ t \ \textit{T} \rightarrow \\ \text{has\_type empty} \ t' \ \textit{U} \rightarrow \end{array}
```

has_type Gamma ([x := t'] t) T.

One technical subtlety in the statement of the lemma is that we assign t' the type U in the *empty* context – in other words, we assume t' is closed. This assumption considerably simplifies the T_-Abs case of the proof (compared to assuming $Gamma \vdash t'$: U, which would be the other reasonable assumption at this point) because the context invariance lemma then tells us that t' has type U in any context at all – we don't have to worry about free variables in t' clashing with the variable being introduced into the context by T_-Abs .

Proof: We prove, by induction on t, that, for all T and Gamma, if $Gamma, x: U \vdash t : T$ and $\vdash t' : U$, then $Gamma \vdash [x:=t']t : T$.

- If t is a variable, there are two cases to consider, depending on whether t is x or some other variable.
 - If t = x, then from the fact that Gamma, $x: U \vdash x : T$ we conclude that U = T. We must show that [x:=t']x = t' has type T under Gamma, given the

assumption that t' has type U = T under the empty context. This follows from context invariance: if a closed term has type T in the empty context, it has that type in any context.

- If t is some variable y that is not equal to x, then we need only note that y has the same type under Gamma, x: U as under Gamma.
- If t is an abstraction y:T11. t12, then the IH tells us, for all Gamma' and T', that if $Gamma',x:U \vdash t12:T'$ and $\vdash t':U$, then $Gamma' \vdash [x:=t']t12:T'$.

The substitution in the conclusion behaves differently, depending on whether x and y are the same variable name.

First, suppose x = y. Then, by the definition of substitution, [x:=t']t = t, so we just need to show $Gamma \vdash t : T$. But we know $Gamma,x:U \vdash t : T$, and since the variable y does not appear free in y:T11. t12, the context invariance lemma yields $Gamma \vdash t : T$.

Second, suppose $x \neq y$. We know $Gamma, x: U, y: T11 \vdash t12 : T12$ by inversion of the typing relation, and $Gamma, y: T11, x: U \vdash t12 : T12$ follows from this by the context invariance lemma, so the IH applies, giving us $Gamma, y: T11 \vdash [x:=t']t12 : T12$. By T_Abs , $Gamma \vdash \y: T11$. $[x:=t']t12 : T11 \rightarrow T12$, and by the definition of substitution (noting that $x \neq y$), $Gamma \vdash \y: T11$. $[x:=t']t12 : T11 \rightarrow T12$ as required.

- If t is an application t1 t2, the result follows straightforwardly from the definition of substitution and the induction hypotheses.
- The remaining cases are similar to the application case.

Another technical note: This proof is a rare case where an induction on terms, rather than typing derivations, yields a simpler argument. The reason for this is that the assumption has_type (extend $Gamma\ x\ U$) $t\ T$ is not completely generic, in the sense that one of the "slots" in the typing relation – namely the context – is not just a variable, and this means that Coq's native induction tactic does not give us the induction hypothesis that we want. It is possible to work around this, but the needed generalization is a little tricky. The term t, on the other hand, is completely generic.

```
Proof with eauto.
```

```
intros Gamma \ x \ U \ t \ t' \ T \ Ht \ Ht'. generalize dependent Gamma. generalize dependent T. t\_cases (induction t) Case; intros T \ Gamma \ H; inversion H; subst; simpl... Case "tvar". rename i into y. remember (beq_id x y) as e. destruct e. SCase "x=y".

      apply beg_id_eq in Hege 0. subst.
      rewrite \leftarrow Hege...
Qed.
```

The substitution lemma can be viewed as a kind of "commutation" property. Intuitively, it says that substitution and typing can be done in either order: we can either assign types to the terms t and v separately (under suitable contexts) and then combine them using substitution, or we can substitute first and then assign a type to [x:=v] t – the result is the same either way.

Preservation

We now have the tools we need to prove *preservation*: if a closed term t has type T, and takes an evaluation step to t, then t is also a closed term with type T. In other words, the small-step evaluation relation preserves types.

```
Theorem preservation : \forall t \ t' \ T,

has_type empty t \ T \rightarrow

t \Longrightarrow t' \rightarrow

has_type empty t' \ T.

Proof: by induction on the derivation of \vdash t : T.
```

• We can immediately rule out T_-Var , T_-Abs , T_-True , and T_-False as the final rules in the derivation, since in each of these cases t cannot take a step.

- If the last rule in the derivation was T_-App , then t = t1 t2. There are three cases to consider, one for each rule that could have been used to show that t1 t2 takes a step to t'.
 - If t1 t2 takes a step by ST_App1 , with t1 stepping to t1, then by the IH t1 has the same type as t1, and hence t1 t2 has the same type as t1 t2.
 - The ST_App2 case is similar.
 - If t1 t2 takes a step by ST_AppAbs , then $t1 = \x:T11.t12$ and t1 t2 steps to [x:=t2]t12; the desired result now follows from the fact that substitution preserves types.
- If the last rule in the derivation was $T_{-}If$, then t = if t1 then t2 else t3, and there are again three cases depending on how t steps.
 - If t steps to t2 or t3, the result is immediate, since t2 and t3 have the same type as t.
 - Otherwise, t steps by $ST_{-}If$, and the desired conclusion follows directly from the induction hypothesis.

Proof with eauto.

Exercise: 2 stars, recommended (subject_expansion_stlc) An exercise in Types.v asked about the subject expansion property for the simple language of arithmetic and boolean expressions. Does this property hold for STLC? That is, is it always the case that, if t ==> t' and $has_type\ t'$ T, then $has_type\ t$ T? If so, prove it. If not, give a counter-example.

Type Soundness

Exercise: 2 stars, optional (type_soundness) Put progress and preservation together and show that a well-typed term can *never* reach a stuck state.

```
Definition stuck (t:tm): Prop:= (normal_form step) t \land \neg value t.

Corollary soundness: \forall t \ t' \ T,

has_type empty t \ T \rightarrow
t ==>* \ t' \rightarrow
^{\sim} (stuck t').

Proof.

intros t \ t' \ T \ Hhas_type \ Hmulti. unfold stuck.

intros [Hnf \ Hnot\_val]. unfold normal_form in Hnf.

induction Hmulti.

Admitted.
```

Uniqueness of Types

Exercise: 3 stars (types_unique) Another pleasant property of the STLC is that types are unique: a given term (in a given context) has at most one type. Formalize this statement and prove it.

21.2.6 Additional Exercises

Exercise: 1 star (progress_preservation_statement) Without peeking, write down the progress and preservation theorems for the simply typed lambda-calculus. \Box

Exercise: 2 stars (stlc_variation1) Suppose we add a new term zap with the following reduction rule:

 $(ST_Zap) t ==> zap$ and the following typing rule:

(T_Zap) Gamma |- zap : T Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of step
- Progress
- Preservation

Exercise: 2 stars (stlc_variation2) Suppose instead that we add a new term foo with the following reduction rules:

$$(ST_Foo1) (x:A. x) ==> foo$$

(ST_Foo2) foo ==> true Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of step
- Progress
- Preservation

Exercise: 2 stars (stlc_variation3) Suppose instead that we remove the rule ST_App1 from the step relation. Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of step
- Progress
- Preservation

Exercise: 2 stars (stlc_variation4) Suppose instead that we add the following new rule to the reduction relation:

(ST_FunnyIfTrue) (if true then t1 else t2) ==> true Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of step
- Progress
- Preservation

Exercise: 2 stars (stlc_variation5) Suppose instead that we add the following new rule to the typing relation: Gamma |- t1 : Bool->Bool->Bool Gamma |- t2 : Bool

(T_FunnyApp) Gamma |- t1 t2 : Bool Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of step
- Progress
- Preservation

Exercise: 2 stars (stlc_variation6) Suppose instead that we add the following new rule to the typing relation: Gamma |- t1 : Bool Gamma |- t2 : Bool

(T_FunnyApp') Gamma |- t1 t2 : Bool Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of step
- Progress
- Preservation

Exercise: 2 stars (stlc_variation7) Suppose we add the following new rule to the typing relation of the STLC:

(T_FunnyAbs) |- \x:Bool.t : Bool Which of the following properties of the STLC remain true in the presence of this rule? For each one, write either "remains true" or else "becomes false." If a property becomes false, give a counterexample.

- Determinism of step
- Progress
- Preservation

End STLC.

21.3 Optional Exercise: STLC with Arithmetic

To see how the STLC might function as the core of a real programming language, let's extend it with a concrete base type of numbers and some constants and primitive operators.

Module STLCARITH.

21.3.1 Syntax and Operational Semantics

To types, we add a base type of natural numbers (and remove booleans, for brevity)

```
\begin{array}{l} \texttt{Inductive } \ \textbf{ty} : \texttt{Type} := \\ \mid \mathsf{TArrow} : \ \textbf{ty} \to \textbf{ty} \to \textbf{ty} \\ \mid \mathsf{TNat} : \ \textbf{ty}. \end{array}
```

To terms, we add natural number constants, along with successor, predecessor, multiplication, and zero-testing...

```
Inductive tm: Type :=  | tvar: id \rightarrow tm | tapp: tm \rightarrow tm \rightarrow tm | tabs: id \rightarrow ty \rightarrow tm \rightarrow tm | tabs: id \rightarrow ty \rightarrow tm | tnat: nat \rightarrow tm | tsucc: tm \rightarrow tm | tpred: tm \rightarrow tm | tmult: tm \rightarrow tm \rightarrow tm | tif0: tm \rightarrow tm \rightarrow tm | tif0: tm \rightarrow tm \rightarrow tm.

Tactic Notation "t_cases" tactic(first) \ ident(c) := first; [ Case\_aux \ c "tvar" | Case\_aux \ c "tapp" | Case\_aux \ c "tvat" | Case\_aux \ c "tnat" | Case\_aux \ c "trat" | Case\_aux \ c "tpred" | Case\_aux \ c "tmult" | Case\_aux \ c "tif0" |.
```

Exercise: 4 stars, optional (stlc_arith) Finish formalizing the definition and properties of the STLC extended with arithmetic. Specifically:

- Copy the whole development of STLC that we went through above (from the definition of values through the Progress theorem), and paste it into the file at this point.
- Extend the definitions of the subst operation and the *step* relation to include appropriate clauses for the arithmetic operators.
- Extend the proofs of all the properties of the original STLC to deal with the new syntactic forms. Make sure Coq accepts the whole file.

End STLCARITH.

Chapter 22

Library Typechecking

22.1 MoreStlc: A Typechecker for STLC

Require Export Stlc.

The has_type relation of the STLC defines what it means for a term to belong to a type (in some context). But it doesn't, by itself, tell us how to check whether or not a term is well typed.

Fortunately, the rules defining has_type are syntax directed – they exactly follow the shape of the term. This makes it straightforward to translate the typing rules into clauses of a typechecking function that takes a term and a context and either returns the term's type or else signals that the term is not typable.

```
Module STLCCHECKER. Import STLC.
```

22.1.1 Comparing Types

First, we need a function to compare two types for equality...

```
Fixpoint beq_ty (T1 \ T2:\mathbf{ty}): \mathbf{bool}:= match T1,T2 with | \ \mathsf{TBool}, \ \mathsf{TBool} \Rightarrow true | \ \mathsf{TArrow} \ T11 \ T12, \ \mathsf{TArrow} \ T21 \ T22 \Rightarrow andb (\mathsf{beq\_ty} \ T11 \ T21) \ (\mathsf{beq\_ty} \ T12 \ T22) | \ \mathsf{-,-} \Rightarrow false end.
```

... and we need to establish the usual two-way connection between the boolean result returned by beq_ty and the logical proposition that its inputs are equal.

```
Lemma beq_ty_refl : \forall T1,
```

```
beq_ty T1 T1 = true.

Proof.

apply andb_true in H0. inversion H0 as [Hbeq1 Hbeq2].

apply IHT1_-1 in Hbeq1. apply IHT1_-2 in Hbeq2. subst... Qed.
```

22.1.2 The Typechecker

Now here's the typechecker. It works by walking over the structure of the given term, returning either $Some\ T$ or None. Each time we make a recursive call to find out the types of the subterms, we need to pattern-match on the results to make sure that they are not None. Also, in the tapp case, we use pattern matching to extract the left- and right-hand sides of the function's arrow type (and fail if the type of the function is not $TArrow\ T11\ T12$ for some T1 and T2).

```
Fixpoint type_check (Gamma:context) (t:tm) : option ty :=
  match t with
    tvar x \Rightarrow Gamma \ x
   | tabs x T11 t12 \Rightarrow \mathtt{match} type_check (extend Gamma \ x T11) t12 with
                                   Some T12 \Rightarrow Some (TArrow T11 T12)
                                  \downarrow \_ \Rightarrow \mathsf{None}
                                end
  | tapp t1 t2 \Rightarrow match type_check Gamma t1, type_check Gamma t2 with
                             | Some (TArrow T11 T12), Some T2 \Rightarrow
                                if beq_ty T11 T2 then Some T12 else None
                             | \_,\_ \Rightarrow \mathsf{None}
                           end
   ttrue \Rightarrow Some TBool
    tfalse \Rightarrow Some TBool
   tif x \ t \ f \Rightarrow \mathtt{match} type_check Gamma \ x with
                            | Some TBool \Rightarrow
                              match type_check Gamma\ t, type_check Gamma\ f with
                                 | Some T1, Some T2 \Rightarrow
                                    if beq_ty T1 T2 then Some T1 else None
```

```
\begin{array}{c} \mid \_,\_ \Rightarrow \mathsf{None} \\ \mathsf{end} \\ \mid \_ \Rightarrow \mathsf{None} \\ \mathsf{end} \end{array}
```

end.

22.1.3 Properties

To verify that this typechecking algorithm is the correct one, we show that it is *sound* and *complete* for the original *has_type* relation – that is, *type_check* and *has_type* define the same partial function.

```
Theorem type_checking_sound : \forall Gamma \ t \ T,

Chapter 23

Library MoreStlc

23.1 MoreStlc: More on the Simply Typed Lambda-Calculus

Require Export Stlc.

23.2 Simple Extensions to STLC

The simply typed lambda-calculus has enough structure to make its theoretical properties interesting, but it is not yet much of a programming language. In this chapter, we begin to close the gap with real-world languages by introducing a number of familiar features that have straightforward treatments at the level of typing.

23.2.1 Numbers

Adding types, constants, and primitive operations for numbers is easy - just a matter of combining the Types and Stlc chapters.

23.2.2 let-bindings

When writing a complex expression, it is often useful to give names to some of its subexpressions: this avoids repetition and often increases readability. Most languages provide one or more ways of doing this. In OCaml (and Coq), for example, we can write let x=t1 in t2 to mean "evaluate the expression t1 and bind the name x to the resulting value while evaluating t2."

Our let-binder follows OCaml's in choosing a call-by-value evaluation order, where the let-bound term must be fully evaluated before evaluation of the let-body can begin. The typing rule T_-Let tells us that the type of a let can be calculated by calculating the type of the let-bound term, extending the context with a binding with this type, and in this enriched context calculating the type of the body, which is then the type of the whole let expression.

At this point in the course, it's probably easier simply to look at the rules defining this new feature as to wade through a lot of english text conveying the same information. Here they are:

Syntax:

Reduction: t1 ==> t1

```
(ST_Let1) let x=t1 in t2 ==> let x=t1' in t2
```

```
(ST_LetValue) let x=v1 in t2 ==> x:=v1t2 Typing: Gamma |- t1 : T1 Gamma , x:T1 |- t2 : T2
```

```
(T_Let) Gamma |- let x=t1 in t2 : T2
```

23.2.3 Pairs

Our functional programming examples in Coq have made frequent use of *pairs* of values. The type of such pairs is called a *product type*.

The formalization of pairs is almost too simple to be worth discussing. However, let's look briefly at the various parts of the definition to emphasize the common pattern.

In Coq, the primitive way of extracting the components of a pair is *pattern matching*. An alternative style is to take fst and snd – the first- and second-projection operators – as primitives. Just for fun, let's do our products this way. For example, here's how we'd write a function that takes a pair of numbers and returns the pair of their sum and difference:

```
\x:Nat*Nat.
let sum = x.fst + x.snd in
let diff = x.fst - x.snd in
(sum,diff)
```

Adding pairs to the simply typed lambda-calculus, then, involves adding two new forms of term – pairing, written (t1,t2), and projection, written t.fst for the first projection from t and t.snd for the second projection – plus one new type constructor, $T1 \times T2$, called the product of T1 and T2.

Syntax:

For evaluation, we need several new rules specifying how pairs and projection behave. t1 = > t1'

```
(ST_Pair1) (t1,t2) ==> (t1',t2)

t2 ==> t2'

(ST_Pair2) (v1,t2) ==> (v1,t2')

t1 ==> t1'

(ST_Fst1) t1.fst ==> t1'.fst

(ST_FstPair) (v1,v2).fst ==> v1

t1 ==> t1'

(ST_Snd1) t1.snd ==> t1'.snd
```

```
(ST\_SndPair) (v1,v2).snd ==> v2
```

Rules $ST_-FstPair$ and $ST_-SndPair$ specify that, when a fully evaluated pair meets a first or second projection, the result is the appropriate component. The congruence rules ST_-Fst1 and ST_-Snd1 allow reduction to proceed under projections, when the term being projected from has not yet been fully evaluated. ST_-Pair1 and ST_-Pair2 evaluate the parts of pairs: first the left part, and then – when a value appears on the left – the right part. The ordering arising from the use of the metavariables v and t in these rules enforces a left-to-right evaluation strategy for pairs. (Note the implicit convention that metavariables like v and v1 can only denote values.) We've also added a clause to the definition of values, above, specifying that (v1,v2) is a value. The fact that the components of a pair value must themselves be values ensures that a pair passed as an argument to a function will be fully evaluated before the function body starts executing.

The typing rules for pairs and projections are straightforward. Gamma \mid - t1 : T1 Gamma \mid - t2 : T2

```
(T_Pair) Gamma |- (t1,t2) : T1*T2
Gamma |- t1 : T11*T12
```

(T_Fst) Gamma |- t1.fst : T11 Gamma |- t1 : T11*T12

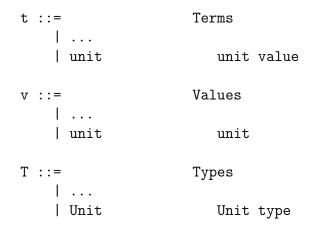

(T_Snd) Gamma |- t1.snd : T12

The rule T_-Pair says that (t1,t2) has type $T1 \times T2$ if t1 has type T1 and t2 has type T2. Conversely, the rules T_-Fst and T_-Snd tell us that, if t1 has a product type $T11 \times T12$ (i.e., if it will evaluate to a pair), then the types of the projections from this pair are T11 and T12.

23.2.4 Unit

Another handy base type, found especially in languages in the ML family, is the singleton type Unit. It has a single element – the term constant unit (with a small u) – and a typing rule making unit an element of Unit. We also add unit to the set of possible result values of computations – indeed, unit is the only possible result of evaluating an expression of type Unit.

Syntax:

Typing:

(T_Unit) Gamma |- unit : Unit

It may seem a little strange to bother defining a type that has just one element – after all, wouldn't every computation living in such a type be trivial?

This is a fair question, and indeed in the STLC the *Unit* type is not especially critical (though we'll see two uses for it below). Where *Unit* really comes in handy is in richer languages with various sorts of *side effects* – e.g., assignment statements that mutate variables or pointers, exceptions and other sorts of nonlocal control structures, etc. In such languages, it is convenient to have a type for the (trivial) result of an expression that is evaluated only for its effect.

23.2.5 Sums

Many programs need to deal with values that can take two distinct forms. For example, we might identify employees in an accounting application using using *either* their name *or* their id number. A search function might return *either* a matching value *or* an error code.

These are specific examples of a binary *sum type*, which describes a set of values drawn from exactly two given types, e.g.

```
Nat + Bool
```

We create elements of these types by tagging elements of the component types. For example, if n is a Nat then inl v is an element of Nat+Bool; similarly, if b is a Bool then inr b is a Nat+Bool. The names of the tags inl and inr arise from thinking of them as functions

```
inl : Nat -> Nat + Bool
inr : Bool -> Nat + Bool
```

that "inject" elements of Nat or Bool into the left and right components of the sum type Nat+Bool. (But note that we don't actually treat them as functions in the way we formalize them: inl and inr are keywords, and inl t and inr t are primitive syntactic forms, not function applications. This allows us to give them their own special typing rules.)

In general, the elements of a type T1 + T2 consist of the elements of T1 tagged with the token inl, plus the elements of T2 tagged with inr.

One important usage of sums is signaling errors:

```
div : Nat -> Nat -> (Nat + Unit) =
div =
  \x:Nat. \y:Nat.
  if iszero y then
    inr Nat unit
  else
  inl String ...
```

The type Nat + Unit above is in fact isomorphic to *option nat* in Coq, and we've already seen how to signal errors with options.

To use elements of sum types, we introduce a case construct (a very simplified form of Coq's match) to destruct them. For example, the following procedure converts a Nat+Bool into a Nat:

```
getNat =
  \x:Nat+Bool.
  case x of
    inl n => n
  | inr b => if b then 1 else 0
```

```
More formally...
   Syntax:
       t ::=
                               Terms
            | inl T t
                                   tagging (left)
            | inr T t
                                   tagging (right)
            | case t of
                                   case
                 inl x => t
               | inr x => t
       v ::=
                               Values
            | ...
            | inl T v
                                   tagged value (left)
            | inr T v
                                   tagged value (right)
       T ::=
                               Types
            | ...
            | T + T
                                   sum type
   Evaluation:
   t1 ==> t1'
(ST_Inl) inl T t1 ==> inl T t1'
   t1 ==> t1'
(ST_Inr) inr T t1 ==> inr T t1'
   t0 ==> t0'
(ST\_Case) case t0 of inl x1 => t1 | inr x2 => t2 ==> case t0' of inl x1 => t1 | inr x2 =>
t2
(ST_CaseInl) case (inl T v0) of inl x1 => t1 | inr x2 => t2 ==> x1:=v0t1
(ST_CaseInr) case (inr T v0) of inl x1 => t1 | inr x2 => t2 ==> x2:=v\thetat2
```

Typing: Gamma |- t1 : T1

Gamma |- t1 : T2

 (T_Inl) Gamma |- inl T2 t1 : T1 + T2

```
(T_Case) Gamma |- case t0 of inl x1 => t1 | inr x2 => t2 : T
```

The reason for the type annotation on the inl and inr forms has to do with uniqueness of types. Without this extra information, the typing rule T_-Inl , for example, would have to say that, once we have shown that t1 is an element of type T1, we can derive that inl t1 is an element of T1 + T2 for any type T2. For example, we could derive both inl 5: Nat + Nat and inl 5: Nat + Bool (and infinitely many other types). This failure of uniqueness of types would mean that we cannot build a typechecking algorithm simply by "reading the rules from bottom to top" as we could for all the other features seen so far.

There are various ways to deal with this difficulty. One simple one – which we've adopted here – forces the programmer to explicitly annotate the "other side" of a sum type when performing an injection. This is rather heavyweight for programmers (and so real languages adopt other solutions), but it is easy to understand and formalize.

23.2.6 Lists

The typing features we have seen can be classified into base types like Bool, and type constructors like \rightarrow and \times that build new types from old ones. Another useful type constructor is List. For every type T, the type List T describes finite-length lists whose elements are drawn from T.

In principle, we could encode lists using pairs, sums and *recursive* types. But giving semantics to recursive types is non-trivial. Instead, we'll just discuss the special case of lists directly.

Below we give the syntax, semantics, and typing rules for lists. Except for the fact that explicit type annotations are mandatory on *nil* and cannot appear on *cons*, these lists are essentially identical to those we built in Coq. We use *lcase* to destruct lists, to avoid dealing with questions like "what is the *head* of the empty list?"

For example, here is a function that calculates the sum of the first two elements of a list of numbers:

```
\x:List Nat.
lcase x of nil -> 0
    | a::x' -> lcase x' of nil -> a
    | b::x'' -> a+b
```

While we say that $cons \ v1 \ v2$ is a value, we really mean that v2 should also be a list – we'll have to enforce this in the formal definition of value.

Syntax:

```
v ::=
                                 Values
             | ...
             | nil T
                                    nil value
             cons v v
                                    cons value
        T ::=
                                 Types
             | ...
             | List T
                                    list of Ts
Reduction: t1 ==> t1'
(ST\_Cons1) cons t1 t2 ==> cons t1' t2
   t2 ==> t2'
(ST\_Cons2) cons v1 t2 ==> cons v1 t2'
   t1 ==> t1'
(ST_Lcase 1) (lcase t1 of nil -> t2 | xh::xt -> t3) ==> (lcase t1' of nil -> t2 | xh::xt -> t3)
(ST_LcaseNil) (lcase nil T of nil -> t2 | xh::xt -> t3) ==> t2
(ST_LcaseCons) (lcase (cons vh vt) of nil -> t2 \mid xh::xt -> t3) ==> xh:=vh,xt:=vtt3
   Typing:
(T_Nil) Gamma |- nil T : List T
   Gamma |- t1 : T Gamma |- t2 : List T
(T_Cons) Gamma |- cons t1 t2: List T
   Gamma |- t1 : List T1 Gamma |- t2 : T Gamma , h:T1, t:List T1 |- t3 : T
(T_L case) Gamma |- (lcase\ t1\ of\ nil\ ->\ t2\ |\ h::t\ ->\ t3): T
```

23.2.7 General Recursion

Another facility found in most programming languages (including Coq) is the ability to define recursive functions. For example, we might like to be able to define the factorial function like this:

```
fact = \x:Nat.
if x=0 then 1 else x * (fact (pred x)))
```

But this would require quite a bit of work to formalize: we'd have to introduce a notion of "function definitions" and carry around an "environment" of such definitions in the definition of the *step* relation.

Here is another way that is straightforward to formalize: instead of writing recursive definitions where the right-hand side can contain the identifier being defined, we can define a *fixed-point operator* that performs the "unfolding" of the recursive definition in the right-hand side lazily during reduction.

```
fact =
    fix
        (\f:Nat->Nat.
        \x:Nat.
        if x=0 then 1 else x * (f (pred x)))
```

The intuition is that the higher-order function f passed to fix is a generator for the fact function: if fact is applied to a function that approximates the desired behavior of fact up to some number n (that is, a function that returns correct results on inputs less than or equal to n), then it returns a better approximation to fact – a function that returns correct results for inputs up to n+1. Applying fix to this generator returns its fixed point – a function that gives the desired behavior for all inputs n.

(The term "fixed point" has exactly the same sense as in ordinary mathematics, where a fixed point of a function f is an input x such that f(x) = x. Here, a fixed point of a function F of type (say) $(Nat \rightarrow Nat) - (Nat \rightarrow Nat)$ is a function f such that F f is behaviorally equivalent to f.)

Syntax:

Reduction: t1 ==> t1

```
(ST_Fix1) fix t1 ==> fix t1'

F = \xspace xf:T1.t2
```

```
(ST_FixAbs) fix F ==> xf:=fix Ft2 Typing: Gamma |-t1:T1->T1
```

```
(T_Fix) Gamma |- fix t1 : T1
```

Let's see how ST_FixAbs works by reducing $fact\ 3 = fix\ F\ 3$, where $F = (\f.\ \x)$ if x=0 then 1 else $x \times (f\ (pred\ x))$ (we are omitting type annotations for brevity here).

```
fix F 3
```

```
==> ST_FixAbs
```

```
(\x. if x=0 then 1 else x * (fix F (pred x))) 3
```

```
==> ST\_AppAbs
```

```
if 3=0 then 1 else 3 * (fix F (pred 3))
==> ST_If0_Nonzero
3 * (fix F (pred 3))
==> ST\_FixAbs + ST\_Mult2
3 * ((\x). if x=0 then 1 else x * (fix F (pred x))) (pred 3))
==>ST\_PredNat+ST\_Mult2+ST\_App2
3 * ((\x . if x=0 then 1 else x * (fix F (pred x))) 2)
==> ST\_AppAbs + ST\_Mult2
3 * (if 2=0 then 1 else 2 * (fix F (pred 2)))
==> ST\_If0\_Nonzero + ST\_Mult2
3 * (2 * (fix F (pred 2)))
==> ST_FixAbs + 2 x ST_Mult2
3 * (2 * ((\x. if x=0 then 1 else x * (fix F (pred x))) (pred 2)))
==> ST\_PredNat + 2 \times ST\_Mult2 + ST\_App2
3 * (2 * ((\x. if x=0 then 1 else x * (fix F (pred x))) 1))
==> ST\_AppAbs + 2 \times ST\_Mult2
3 * (2 * (if 1=0 then 1 else 1 * (fix F (pred 1))))
==> ST_If0_Nonzero + 2 \times ST_Mult2
3 * (2 * (1 * (fix F (pred 1))))
==> ST_FixAbs + 3 \times ST_Mult2
3 * (2 * (1 * ((\x. if x=0 then 1 else x * (fix F (pred x))) (pred 1))))
==> ST\_PredNat + 3 \times ST\_Mult2 + ST\_App2
3 * (2 * (1 * ((\x. if x=0 then 1 else x * (fix F (pred x))) 0)))
==> ST\_AppAbs + 3 \times ST\_Mult2
3 * (2 * (1 * (if 0=0 then 1 else 0 * (fix F (pred 0)))))
==> ST_If0Zero + 3 \times ST_Mult2
3 * (2 * (1 * 1))
==> ST\_MultNats + 2 \times ST\_Mult2
3 * (2 * 1)
==> ST\_MultNats + ST\_Mult2
3 * 2
==> ST\_MultNats
```

Exercise: 1 star (halve_fix) Translate this informal recursive definition into one using fix:

```
halve =
  \x:Nat.
  if x=0 then 0
  else if (pred x)=0 then 0
  else 1 + (halve (pred (pred x))))
```

Exercise: 1 star, recommended (fact_steps) Write down the sequence of steps that the term fact 1 goes through to reduce to a normal form (assuming the usual reduction rules for arithmetic operations).

The ability to form the fixed point of a function of type $T \to T$ for any T has some surprising consequences. In particular, it implies that *every* type is inhabited by some term. To see this, observe that, for every type T, we can define the term fix (\x:T.x) By T_-Fix and T_-Abs , this term has type T. By $ST_-FixAbs$ it reduces to itself, over and over again. Thus it is an *undefined element* of T.

More usefully, here's an example using fix to define a two-argument recursive function:

```
equal =
  fix
  (\eq:Nat->Nat->Bool.
  \m:Nat. \n:Nat.
    if m=0 then iszero n
    else if n=0 then false
    else eq (pred m) (pred n))
```

And finally, here is an example where fix is used to define a *pair* of recursive functions (illustrating the fact that the type T1 in the rule T_-Fix need not be a function type):

```
evenodd =
  fix
    (\eo: (Nat->Bool * Nat->Bool).
     let e = \n:Nat. if n=0 then true else eo.snd (pred n) in
     let o = \n:Nat. if n=0 then false else eo.fst (pred n) in
        (e,o))

even = evenodd.fst
odd = evenodd.snd
```

23.2.8 Records

As a final example of a basic extension of the STLC, let's look briefly at how to define *records* and their types. Intuitively, records can be obtained from pairs by two kinds of generalization: they are n-ary products (rather than just binary) and their fields are accessed by *label* (rather than position).

This extension is conceptually a straightforward generalization of pairs and product types, but notationally it becomes a little heavier; for this reason, we postpone its formal treatment to a separate chapter (Records). Therefore records are not included in the extended exercise below, but they are used to motivate the Subtyping chapter.

Syntax:

Intuitively, the generalization is pretty obvious. But it's worth noticing that what we've actually written is rather informal: in particular, we've written "..." in several places to mean "any number of these," and we've omitted explicit mention of the usual side-condition that the labels of a record should not contain repetitions. It is possible to devise informal notations that are more precise, but these tend to be quite heavy and to obscure the main points of the definitions. So we'll leave these a bit loose here (they are informal anyway, after all) and do the work of tightening things up elsewhere (in chapter *Records*).

Reduction: ti ==> ti'

```
 \begin{array}{l} (ST\_Rcd) \; \{i1=v1, \, ..., \, im=vm, \, in=ti, \, ...\} ==> \{i1=v1, \, ..., \, im=vm, \, in=ti', \, ...\} \\ t1 ==> t1' \\ \\ (ST\_Proj1) \; t1.i ==> t1'.i \\ \end{array}
```

(ST_ProjRcd) $\{..., i=vi, ...\}$. i==>vi Again, these rules are a bit informal. For example, the first rule is intended to be read "if ti is the leftmost field that is not a value and if ti steps to ti", then the whole record steps..." In the last rule, the intention is that there should only be one field called i, and that all the other fields must contain values.

Typing: Gamma |- t1 : T1 ... Gamma |- tn : Tn

```
(T_Rcd) Gamma |- {i1=t1, ..., in=tn} : {i1:T1, ..., in:Tn} Gamma |- t : {..., i:Ti, ...}
```

```
(T_Proj) Gamma |- t.i : Ti
```

Encoding Records (Optional)

There are several ways to make the above definitions precise.

- We can directly formalize the syntactic forms and inference rules, staying as close as possible to the form we've given them above. This is conceptually straightforward, and it's probably what we'd want to do if we were building a real compiler in particular, it will allow is to print error messages in the form that programmers will find easy to understand. But the formal versions of the rules will not be pretty at all!
- We could look for a smoother way of presenting records for example, a binary presentation with one constructor for the empty record and another constructor for adding a single field to an existing record, instead of a single monolithic constructor that builds a whole record at once. This is the right way to go if we are primarily interested in studying the metatheory of the calculi with records, since it leads to clean and elegant definitions and proofs. Chapter *Records* shows how this can be done.
- Alternatively, if we like, we can avoid formalizing records altogether, by stipulating that record notations are just informal shorthands for more complex expressions involving pairs and product types. We sketch this approach here.

First, observe that we can encode arbitrary-size tuples using nested pairs and the *unit* value. To avoid overloading the pair notation (t1,t2), we'll use curly braces without labels to write down tuples, so $\{\}$ is the empty tuple, $\{5\}$ is a singleton tuple, $\{5,6\}$ is a 2-tuple (morally the same as a pair), $\{5,6,7\}$ is a triple, etc.

```
{\tau_{t1}, t2, \ldots, tn\} \quad \quad \tau_{t1}, \tau_{t2}, \tau_{t1}, \tau_{t2}, \tau_{t2}, \tau_{t3}, \tau_{t4} \tau_{t4} \tau_{t4} \tau_{t5}
```

Similarly, we can encode tuple types using nested product types:

```
{T1, T2, ..., Tn} ----> Unit

where {T2, ..., Tn} ----> TRest
```

The operation of projecting a field from a tuple can be encoded using a sequence of second projections followed by a first projection:

```
t.0 ----> t.fst
t.(n+1) ----> (t.snd).n
```

Next, suppose that there is some total ordering on record labels, so that we can associate each label with a unique natural number. This number is called the *position* of the label. For example, we might assign positions like this:

LABEL	POSITION
a	0
b	1
С	2
foo	1004
 bar	 10562

We use these positions to encode record values as tuples (i.e., as nested pairs) by sorting the fields according to their positions. For example:

```
{a=5, b=6} ----> {5,6}

{a=5, c=7} ----> {5,unit,7}

{c=7, a=5} ----> {5,unit,7}

{c=5, b=3} ----> {unit,3,5}

{f=8,c=5,a=7} ----> {7,unit,5,unit,unit,8}

{f=8,c=5} ----> {unit,5,unit,unit,8}
```

Note that each field appears in the position associated with its label, that the size of the tuple is determined by the label with the highest position, and that we fill in unused positions with *unit*.

We do exactly the same thing with record types:

Finally, record projection is encoded as a tuple projection from the appropriate position:

```
t.l ---> t.(position of 1)
```

It is not hard to check that all the typing rules for the original "direct" presentation of records are validated by this encoding. (The reduction rules are "almost validated" – not quite, because the encoding reorders fields.)

Of course, this encoding will not be very efficient if we happen to use a record with label bar! But things are not actually as bad as they might seem: for example, if we assume that our compiler can see the whole program at the same time, we can *choose* the numbering of labels so that we assign small positions to the most frequently used labels. Indeed, there are industrial compilers that essentially do this!

Variants (Optional Reading)

Just as products can be generalized to records, sums can be generalized to n-ary labeled types called *variants*. Instead of T1+T2, we can write something like $\langle l1:T1,l2:T2,...ln:Tn\rangle$ where l1,l2,... are field labels which are used both to build instances and as case arm labels.

These n-ary variants give us almost enough mechanism to build arbitrary inductive data types like lists and trees from scratch – the only thing missing is a way to allow *recursion* in type definitions. We won't cover this here, but detailed treatments can be found in many textbooks – e.g., Types and Programming Languages.

23.3 Exercise: Formalizing the Extensions

Exercise: 4 stars, recommended (STLC_extensions) Formalizing the extensions (not including the optional ones) is left to you. We've provided the necessary extensions to the syntax of terms and types, and we've included a few examples that you can test your definitions with to make sure they are working as expected. You'll fill in the rest of the definitions and extend all the proofs accordingly.

A good strategy is to work on the extensions one at a time, in multiple passes, rather than trying to work through the file from start to finish in a single pass. For each definition or proof, begin by reading carefully through the parts that are provided for you, referring to the text in the *Stlc* chapter for high-level intuitions and the embedded comments for detailed mechanics.

A good order for attempting the extensions is:

- numbers first (since they are both familiar and simple)
- products and units
- let (which involves binding)
- sums (which involve slightly more complex binding)
- lists (which involve yet more complex binding)
- fix

Module STLCEXTENDED.

Syntax and Operational Semantics

```
\begin{array}{l} \texttt{Inductive } \ \textbf{ty} : \texttt{Type} := \\ | \ \mathsf{TArrow} : \ \textbf{ty} \to \textbf{ty} \to \textbf{ty} \\ | \ \mathsf{TNat} : \ \textbf{ty} \\ | \ \mathsf{TUnit} : \ \textbf{ty} \end{array}

Typing
```

Definition context := partial_map ty.

Next we define the typing rules. These are nearly direct transcriptions of the inference rules shown above.

Inductive has_type : context \rightarrow tm \rightarrow ty \rightarrow Prop :=

```
 | \ \mathsf{T_-Var} : \forall \ Gamma \ x \ T, \\ Gamma \ x = \mathsf{Some} \ T \to \\ \mathsf{has\_type} \ Gamma \ (\mathsf{tvar} \ x) \ T \\ | \ \mathsf{T_-Abs} : \forall \ Gamma \ x \ T11 \ T12 \ t12, \\ \mathsf{has\_type} \ (\mathsf{extend} \ Gamma \ x \ T11) \ t12 \ T12 \to \\ \mathsf{has\_type} \ Gamma \ (\mathsf{tabs} \ x \ T11 \ t12) \ (\mathsf{TArrow} \ T11 \ T12) \\ | \ \mathsf{T_-App} : \forall \ T1 \ T2 \ Gamma \ t1 \ t2, \\ \mathsf{has\_type} \ Gamma \ t1 \ (\mathsf{TArrow} \ T1 \ T2) \to \\ \mathsf{has\_type} \ Gamma \ t2 \ T1 \to \\ \mathsf{has\_type} \ Gamma \ (\mathsf{tapp} \ t1 \ t2) \ T2 \\
```

Hint Constructors has_type.
Tactic Notation "has_type_cases" tactic(first) ident(c) :=
 first;
 [Case_aux c "T_Var" | Case_aux c "T_Abs" | Case_aux c "T_App"
].

23.3.1 Examples

This section presents formalized versions of the examples from above (plus several more). The ones at the beginning focus on specific features; you can use these to make sure your definition of a given feature is reasonable before moving on to extending the proofs later in the file with the cases relating to this feature. The later examples require all the features together, so you'll need to come back to these when you've got all the definitions filled in.

Module EXAMPLES.

Preliminaries

First, let's define a few variable names:

```
Notation a := (Id 0).
Notation f := (Id 1).
Notation g := (Id 2).
Notation I := (Id 3).
Notation k := (Id 6).
Notation i1 := (Id 7).
Notation i2 := (Id 8).
Notation x := (Id 9).
Notation y := (Id 10).
Notation processSum := (Id 11).
Notation n := (Id 12).
Notation eq := (Id 13).
Notation m := (Id 14).
Notation evenodd := (Id 15).
Notation even := (Id 16).
Notation odd := (Id 17).
Notation eo := (Id 18).
```

Next, a bit of Coq hackery to automate searching for typing derivations. You don't need to understand this bit in detail – just have a look over it so that you'll know what to look for if you ever find yourself needing to make custom extensions to auto.

The following Hint declarations say that, whenever auto arrives at a goal of the form $(has_type\ G\ (tapp\ e1\ e1)\ T)$, it should consider eapply T_App , leaving an existential

variable for the middle type T1, and similar for *lcase*. That variable will then be filled in during the search for type derivations for e1 and e2. We also include a hint to "try harder" when solving equality goals; this is useful to automate uses of $T_{-}Var$ (which includes an equality as a precondition).

```
Hint Extern 2 (has_type \_ (tapp \_ \_) \Rightarrow eapply T_App; auto.
Hint Extern 2 (\_ = \_) \Rightarrow compute; reflexivity.
```

Numbers

```
\label{eq:module_Numtest} \begin{split} \text{Module Numtest.} \\ \text{Definition test} := \\ \text{tifO} \\ \text{(tpred} \\ \text{(tsucc} \\ \text{(tpred} \\ \text{(tmult} \\ \text{(tnat 2)} \\ \text{(tnat 5)} \\ \text{(tnat 6).} \end{split}
```

Remove the comment braces once you've implemented enough of the definitions that you think this should work.

End NUMTEST.

Products

Module LETTEST.

```
Definition test :=
  tlet
    (tpred (tnat 6))
    (tsucc (tvar x)).
End LETTEST.

End STLCEXTENDED.

Chapter 24

Library Records

24.1 Records: Adding Records to STLC

Require Export Stlc.

24.2 Adding Records

We saw in chapter *MoreStlc* how records can be treated as syntactic sugar for nested uses of products. This is fine for simple examples, but the encoding is informal (in reality, if we really treated records this way, it would be carried out in the parser, which we are eliding here), and anyway it is not very efficient. So it is also interesting to see how records can be treated as first-class citizens of the language.

Recall the informal definitions we gave before:

Syntax:

Reduction: ti ==> ti' (ST_Rcd)

```
{i1=v1, ..., im=vm, in=tn, ...} ==> {i1=v1, ..., im=vm, in=tn', ...}
t1 ==> t1'

(ST_Proj1) t1.i ==> t1'.i

(ST_ProjRcd) {..., i=vi, ...}.i ==> vi Typing: Gamma |- t1 : T1 ... Gamma |- tn : Tn

(T_Rcd) Gamma |- {i1=t1, ..., in=tn} : {i1:T1, ..., in:Tn}
Gamma |- t : {..., i:Ti, ...}

(T_Proj) Gamma |- t.i : Ti
```

24.3 Formalizing Records

Module STLCEXTENDEDRECORDS.

Syntax and Operational Semantics

The most obvious way to formalize the syntax of record types would be this:

Module FIRSTTRY.

```
Definition alist (X : \mathsf{Type}) := \mathsf{list} \; (\mathsf{id} \times X).
Inductive \mathsf{ty} : \mathsf{Type} := 
| \; \mathsf{TBase} : \mathsf{id} \to \mathsf{ty} 
| \; \mathsf{TArrow} : \; \mathsf{ty} \to \mathsf{ty} \to \mathsf{ty} 
| \; \mathsf{TRcd} : \; (\mathsf{alist} \; \mathsf{ty}) \to \mathsf{ty}.
```

Unfortunately, we encounter here a limitation in Coq: this type does not automatically give us the induction principle we expect the induction hypothesis in the TRcd case doesn't give us any information about the ty elements of the list, making it useless for the proofs we want to do.

End FIRSTTRY.

It is possible to get a better induction principle out of Coq, but the details of how this is done are not very pretty, and it is not as intuitive to use as the ones Coq generates automatically for simple Inductive definitions.

Fortunately, there is a different way of formalizing records that is, in some ways, even simpler and more natural: instead of using the existing *list* type, we can essentially include its constructors ("nil" and "cons") in the syntax of types.

```
\begin{array}{l} \texttt{Inductive } \ \textbf{ty} : \texttt{Type} := \\ | \ \mathsf{TBase} : \ \textbf{id} \rightarrow \textbf{ty} \\ | \ \mathsf{TArrow} : \ \textbf{ty} \rightarrow \textbf{ty} \rightarrow \textbf{ty} \\ | \ \mathsf{TRNil} : \ \textbf{ty} \end{array}
```

```
| TRCons: id \rightarrow ty \rightarrow ty \rightarrow ty.

Tactic Notation "T_cases" tactic(first) \ ident(c) := first;
[ Case\_aux \ c "TBase" | Case\_aux \ c "TArrow" | Case\_aux \ c "TRNil" | Case\_aux \ c "TRCons" ].
```

Similarly, at the level of terms, we have constructors trnil the empty record – and trcons, which adds a single field to the front of a list of fields.

```
Inductive tm : Type :=
    \mathsf{tvar}:\mathsf{id}\to\mathsf{tm}
    \mathsf{tapp}: \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}
   \mid \mathsf{tabs} : \mathsf{id} 	o \mathsf{ty} 	o \mathsf{tm} 	o \mathsf{tm}
   tproj : \mathsf{tm} \to \mathsf{id} \to \mathsf{tm}
    trnil: tm
   | troons : id \rightarrow tm \rightarrow tm \rightarrow tm.
Tactic Notation "t_cases" tactic(first) ident(c) :=
    Case_aux c "tvar" | Case_aux c "tapp" | Case_aux c "tabs"
    Case_aux c "tproj" | Case_aux c "trnil" | Case_aux c "trcons" ].
    Some variables, for examples...
Notation a := (Id \ 0).
Notation f := (Id 1).
Notation g := (Id 2).
Notation I := (Id 3).
Notation A := (TBase (Id 4)).
Notation B := (TBase (Id 5)).
Notation k := (Id 6).
Notation i1 := (Id 7).
Notation i2 := (Id 8).
    { i1:A }
    \{i1:A\rightarrow B, i2:A\}
```

Well-Formedness

Generalizing our abstract syntax for records (from lists to the nil/cons presentation) introduces the possibility of writing strange types like this

```
Definition weird_type := TRCons X A B.
```

where the "tail" of a record type is not actually a record type!

We'll structure our typing judgement so that no ill-formed types like weird_type are assigned to terms. To support this, we define record_ty and record_tm, which identify record types and terms, and well_formed_ty which rules out the ill-formed types.

First, a type is a record type if it is built with just TRNil and TRCons at the outermost level.

```
Inductive record_ty: ty \rightarrow Prop := |RTnil : record_ty TRNil : record_ty TRNil |RTcons: <math>\forall i \ T1 \ T2, record_ty \ (TRCons \ i \ T1 \ T2).
Similarly, a term is a record term if it is built with trnil and trcons Inductive record_tm : tm \rightarrow Prop := |rtnil : record_tm \ trnil |rtcons: <math>\forall i \ t1 \ t2, record_tm \ (trcons \ i \ t1 \ t2).
```

Note that $record_ty$ and $record_tm$ are not recursive – they just check the outermost constructor. The $well_formed_ty$ property, on the other hand, verifies that the whole type is well formed in the sense that the tail of every record (the second argument to TRCons) is a record.

Of course, we should also be concerned about ill-formed terms, not just types; but type-checking can rules those out without the help of an extra $well_formed_tm$ definition because it already examines the structure of terms. LATER: should they fill in part of this as an exercise? We didn't give rules for it above

Hint Constructors record_ty record_tm well_formed_ty.

Substitution

```
Fixpoint subst (x:id) (s:tm) (t:tm) : tm :=
  match t with
    tvar y \Rightarrow \text{if beq\_id } x \ y \text{ then } s \text{ else } t
    tabs y \ T \ t1 \Rightarrow tabs \ y \ T \ (if beq_id \ x \ y \ then \ t1 \ else \ (subst \ x \ s \ t1))
    tapp t1 t2 \Rightarrow \text{tapp (subst } x \ s \ t1) \ (\text{subst } x \ s \ t2)
    tproj t1 \ i \Rightarrow tproj (subst \ x \ s \ t1) \ i
    trnil \Rightarrow trnil
   | trcons i \ t1 \ tr1 \Rightarrow trcons i \ (subst \ x \ s \ t1) \ (subst \ x \ s \ tr1)
Notation "'[' x := 's ']' t" := (subst x s t) (at level 20).
Reduction
Next we define the values of our language. A record is a value if all of its fields are.
Inductive value : tm \rightarrow Prop :=
  | v_abs : \forall x T11 t12,
        value (tabs x T11 t12)
   | v_rnil : value trnil
  | v_{rcons} : \forall i v1 vr,
        value v1 \rightarrow
        value vr \rightarrow
        value (troons i \ v1 \ vr).
Hint Constructors value.
    Utility functions for extracting one field from record type or term:
Fixpoint Tlookup (i:id) (Tr:ty) : option ty :=
  match Tr with
    TRCons i' T Tr' \Rightarrow if beq_id i' then Some T else Tlookup i Tr'
   | \_ \Rightarrow \mathsf{None}
  end.
Fixpoint tlookup (i:id) (tr:tm) : option tm :=
  match \ tr \ with
   | troons i' t tr' \Rightarrow if beq_id i i' then Some t else tlookup i tr'
  | \_ \Rightarrow \mathsf{None}
  end.
    The step function uses the term-level lookup function (for the projection rule), while the
type-level lookup is needed for has_type.
```

Reserved Notation "t1'==>' t2" (at level 40).

Inductive step: $tm \rightarrow tm \rightarrow Prop :=$

```
| ST_AppAbs : \forall x T11 t12 v2,
           value v2 \rightarrow
            (tapp (tabs x \ T11 \ t12) \ v2) ==> ([x := v2] t12)
  | ST\_App1 : \forall t1 t1' t2,
           t1 ==> t1' \rightarrow
            (tapp t1 t2) ==> (tapp t1' t2)
  | ST\_App2 : \forall v1 \ t2 \ t2',
           value v1 \rightarrow
           t2 ==> t2' \rightarrow
            (tapp v1 t2) ==> (tapp v1 t2')
  | ST_Proj1 : \forall t1 \ t1' i,
          t1 ==> t1' \rightarrow
          (tproj t1 i) ==> (tproj t1' i)
  | ST_ProjRcd : \forall tr i vi,
          value tr \rightarrow
          tlookup i \ tr = Some \ vi \rightarrow
          (tproj tr i) ==> vi
  | ST_Rcd_Head : \forall i t1 t1' tr2,
          t1 ==> t1' \rightarrow
          (trcons i \ t1 \ tr2) ==> (trcons i \ t1' \ tr2)
  | ST_Rcd_Tail : \forall i \ v1 \ tr2 \ tr2',
          value v1 \rightarrow
          tr2 ==> tr2' \rightarrow
          (trcons i \ v1 \ tr2) ==> (trcons i \ v1 \ tr2')
where "t1' ==> t2" := (step \ t1 \ t2).
Tactic Notation "step_cases" tactic(first) ident(c) :=
  first;
    Case_aux c "ST_AppAbs" | Case_aux c "ST_App1" | Case_aux c "ST_App2"
    Case_aux c "ST_Proj1" | Case_aux c "ST_ProjRcd"
    Case_aux c "ST_Rcd_Head" | Case_aux c "ST_Rcd_Tail" ].
Notation multistep := (multi step).
Notation "t1'==>*' t2" := (multistep t1 t2) (at level 40).
Hint Constructors step.
```

Typing

Definition context := partial_map ty.

Next we define the typing rules. These are nearly direct transcriptions of the inference rules shown above. The only major difference is the use of well_formed_ty. In the informal presentation we used a grammar that only allowed well formed record types, so we didn't have to add a separate check.

We'd like to set things up so that that whenever $has_type\ Gamma\ t\ T$ holds, we also have $well_formed_ty\ T$. That is, has_type never assigns ill-formed types to terms. In fact, we prove this theorem below.

However, we don't want to clutter the definition of has_type with unnecessary uses of $well_formed_ty$. Instead, we place $well_formed_ty$ checks only where needed - where an inductive call to has_type won't already be checking the well-formedness of a type.

For example, we check $well_formed_ty\ T$ in the T_Var case, because there is no inductive has_type call that would enforce this. Similarly, in the T_Abs case, we require a proof of $well_formed_ty\ T11$ because the inductive call to has_type only guarantees that T12 is well-formed.

In the rules you must write, the only necessary $well_formed_ty$ check comes in the tnil case.

```
Inductive has_type : context \rightarrow tm \rightarrow ty \rightarrow Prop :=
           T_{-}Var: \forall Gamma \ x \ T,
                       Gamma \ x = Some \ T \rightarrow
                      well_formed_ty T \rightarrow
                      has_type Gamma (tvar x) T
       \mid \mathsf{T}_{-}\mathsf{Abs} : \forall \ Gamma \ x \ T11 \ T12 \ t12,
                      well_formed_ty T11 \rightarrow
                      has_type (extend Gamma \ x \ T11) \ t12 \ T12 \rightarrow
                      has_type Gamma (tabs x T11 t12) (TArrow T11 T12)
       | \mathsf{T}_{-}\mathsf{App} : \forall T1 \ T2 \ Gamma \ t1 \ t2,
                      has_type Gamma\ t1\ (TArrow\ T1\ T2) \rightarrow
                      has_type Gamma\ t2\ T1 \rightarrow
                      has_type Gamma (tapp t1 t2) T2
       | T_{Proj} : \forall Gamma \ i \ t \ Ti \ Tr,
                      has_type Gamma\ t\ Tr \rightarrow
                      The Thomas The The Thomas The The Thomas The The Thomas The The Thomas The The Thomas The Thomas The The Thomas The The 
                      has_type Gamma (tproj t i) Ti
        \mid \mathsf{T}_{\mathsf{-}}\mathsf{RNil} : \forall \ Gamma,
                      has_type Gamma trnil TRNil
        | T_RCons : \forall Gamma \ i \ t \ T \ tr \ Tr,
                      has_type Gamma\ t\ T \rightarrow
                      has_type Gamma\ tr\ Tr \rightarrow
                      record_ty Tr \rightarrow
                      record_tm tr \rightarrow
                      has_type Gamma (trcons i \ t \ tr) (TRCons i \ T \ Tr).
Hint Constructors has_type.

```

24.3.1 Examples

Exercise: 2 stars (examples) Finish the proofs.

Feel free to use Coq's automation features in this proof. However, if you are not confident about how the type system works, you may want to carry out the proof first using the basic features (apply instead of eapply, in particular) and then perhaps compress it using automation.

```
Lemma typing_example_2:
  has_type empty
     (tapp (tabs a (TRCons i1 (TArrow A A)
                          (TRCons i2 (TArrow B B)
                            TRNil))
                 (tproj (tvar a) i2))
              (trcons i1 (tabs a A (tvar a))
              (trcons i2 (tabs a B (tvar a))
               trnil)))
     (TArrow B B).
Proof.
    Admitted.
   Before starting to prove this fact (or the one above!), make sure you understand what it
is saying.
Example typing_nonexample :
  \neg \exists T,
       has_type (extend empty a (TRCons i2 (TArrow A A)
                                      TRNil))
                  (trcons i1 (tabs a B (tvar a)) (tvar a))
Proof.
   Admitted.
Example typing_nonexample_2 : \forall y,
  \neg \exists T,
    has\_type (extend empty y A)
             (tapp (tabs a (TRCons i1 A TRNil)
                         (tproj (tvar a) i1))
                       (trcons i1 (tvar y) (trcons i2 (tvar y) trnil)))
             T.
Proof.
    Admitted.
```

24.3.2 Properties of Typing

The proofs of progress and preservation for this system are essentially the same as for the pure simply typed lambda-calculus, but we need to add some technical lemmas involving records.

Well-Formedness

```
Lemma wf_rcd_lookup : \forall i T Ti,
  well_formed_ty T \rightarrow
  Tlookup i T = Some Ti \rightarrow
  well_formed_ty Ti.
Proof with eauto.

  Case "T_App".
    inversion IHHtyp1...
  Case "T_Proj".
    eapply wf_rcd_lookup...
Qed.
```

Field Lookup

Lemma: If $empty \vdash v$: T and Tlookup i T returns Some Ti, then tlookup i v returns Some ti for some term ti such that $has_type \ empty \ ti \ Ti$.

Proof: By induction on the typing derivation Htyp. Since $Tlookup\ i\ T=Some\ Ti,\ T$ must be a record type, this and the fact that v is a value eliminate most cases by inspection, leaving only the T_-RCons case.

If the last step in the typing derivation is by $T_{-}RCons$, then $t = trcons\ i0\ t\ tr$ and $T = TRCons\ i0\ T\ Tr$ for some i0, t, tr, T and Tr.

This leaves two possiblities to consider - either $i\theta = i$ or not.

- If $i = i\theta$, then since Tlookup i (TRCons $i\theta$ T Tr) = Some Ti we have T = Ti. It follows that t itself satisfies the theorem.
- On the other hand, suppose $i \neq i0$. Then Tlookup i T = Tlookup i Tr and tlookup i t = tlookup i tr, so the result follows from the induction hypothesis. \square

```
Lemma lookup_field_in_value : \forall v \ T \ i \ Ti,
  value v \rightarrow
  has_type empty v T \rightarrow

Chapter 25

Library References

25.1 References: Typing Mutable References

Require Export Smallstep.

So far, we have considered a variety of *pure* language features, including functional abstraction, basic types such as numbers and booleans, and structured types such as records and variants. These features form the backbone of most programming languages – including purely functional languages such as Haskell, "mostly functional" languages such as ML, imperative languages such as C, and object-oriented languages such as Java.

Most practical programming languages also include various *impure* features that cannot be described in the simple semantic framework we have used so far. In particular, besides just yielding results, evaluation of terms in these languages may assign to mutable variables (reference cells, arrays, mutable record fields, etc.), perform input and output to files, displays, or network connections, make non-local transfers of control via exceptions, jumps, or continuations, engage in inter-process synchronization and communication, and so on. In the literature on programming languages, such "side effects" of computation are more generally referred to as *computational effects*.

In this chapter, we'll see how one sort of computational effect – mutable references – can be added to the calculi we have studied. The main extension will be dealing explicitly with a *store* (or *heap*). This extension is straightforward to define; the most interesting part is the refinement we need to make to the statement of the type preservation theorem.

25.1.1 Definitions

Pretty much every programming language provides some form of assignment operation that changes the contents of a previously allocated piece of storage. (Coq's internal language is a rare exception!)

In some languages – notably ML and its relatives – the mechanisms for name-binding and those for assignment are kept separate. We can have a variable x whose value is the number 5, or we can have a variable y whose value is a reference (or pointer) to a mutable

cell whose current contents is 5. These are different things, and the difference is visible to the programmer. We can add x to another number, but not assign to it. We can use y directly to assign a new value to the cell that it points to (by writing y:=84), but we cannot use it directly as an argument to an operation like +. Instead, we must explicitly *dereference* it, writing !y to obtain its current contents.

In most other languages – in particular, in all members of the C family, including Java – *every* variable name refers to a mutable cell, and the operation of dereferencing a variable to obtain its current contents is implicit.

For purposes of formal study, it is useful to keep these mechanisms separate. The development in this chapter will closely follow ML's model. Applying the lessons learned here to C-like languages is a straightforward matter of collapsing some distinctions and rendering some operations such as dereferencing implicit instead of explicit.

In this chapter, we study adding mutable references to the simply-typed lambda calculus with natural numbers.

25.1.2 Syntax

Module STLCREF.

The basic operations on references are allocation, dereferencing, and assignment.

- To allocate a reference, we use the *ref* operator, providing an initial value for the new cell. For example, *ref* 5 creates a new cell containing the value 5, and evaluates to a reference to that cell.
- To read the current value of this cell, we use the dereferencing operator!; for example, !(ref 5) evaluates to 5.
- To change the value stored in a cell, we use the assignment operator. If r is a reference, r := 7 will store the value 7 in the cell referenced by r. However, r := 7 evaluates to the trivial value unit; it exists only to have the side effect of modifying the contents of a cell.

Types

We start with the simply typed lambda calculus over the natural numbers. To the base natural number type and arrow types we need to add two more types to deal with references. First, we need the *unit type*, which we will use as the result type of an assignment operation. We then add reference types. If T is a type, then $Ref\ T$ is the type of references which point to a cell holding values of type T.

```
\label{eq:ty} \begin{array}{l} \text{Inductive } \textbf{ty} : \texttt{Type} := \\ | \ \mathsf{TNat} : \ \textbf{ty} \\ | \ \mathsf{TUnit} : \ \textbf{ty} \\ | \ \mathsf{TArrow} : \ \textbf{ty} \to \textbf{ty} \to \textbf{ty} \\ | \ \mathsf{TRef} : \ \textbf{ty} \to \textbf{ty}. \end{array}
```

Terms

Besides variables, abstractions, applications, natural-number-related terms, and *unit*, we need four more sorts of terms in order to handle mutable references:

Inductive tm : Type :=

```
 | \  \, \mathsf{tvar} : \  \, \mathsf{id} \to \mathsf{tm} \\ | \  \, \mathsf{tapp} : \  \, \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tabs} : \  \, \mathsf{id} \to \mathsf{ty} \to \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tnat} : \  \, \mathsf{nat} \to \mathsf{tm} \\ | \  \, \mathsf{tsucc} : \  \, \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tsucc} : \  \, \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tpred} : \  \, \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tmult} : \  \, \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tif0} : \  \, \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tunit} : \  \, \mathsf{tm} \\ | \  \, \mathsf{tderef} : \  \, \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tderef} : \  \, \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tdssign} : \  \, \mathsf{tm} \to \mathsf{tm} \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{tloc} : \  \, \mathsf{nat} \to \mathsf{tm}. \\ | \  \, \mathsf{nat} \to \mathsf{na
```

Intuitively...

- $ref \ t$ (formally, $tref \ t$) allocates a new reference cell with the value t and evaluates to the location of the newly allocated cell;
- !t (formally, tderef t) evaluates to the contents of the cell referenced by t;
- t1 := t2 (formally, $tassign \ t1 \ t2$) assigns t2 to the cell referenced by t1; and
- l (formally, $tloc\ l$) is a reference to the cell at location l. We'll discuss locations later.

In informal examples, we'll also freely use the extensions of the STLC developed in the *MoreStlc* chapter; however, to keep the proofs small, we won't bother formalizing them again here. It would be easy to do so, since there are no very interesting interactions between those features and references.

```
Tactic Notation "t_cases" tactic(first) ident(c) :=
    first;
    [ Case_aux c "tvar" | Case_aux c "tapp"
        | Case_aux c "tabs" | Case_aux c "tzero"
        | Case_aux c "tsucc" | Case_aux c "tpred"
        | Case_aux c "tmult" | Case_aux c "tif0"
        | Case_aux c "tunit" | Case_aux c "tref"
        | Case_aux c "tderef" | Case_aux c "tassign"
        | Case_aux c "tloc" ].

Module EXAMPLEVARIABLES.

Definition x := Id 0.
Definition r := Id 2.
Definition s := Id 3.
End EXAMPLEVARIABLES.
```

Typing (Preview)

Informally, the typing rules for allocation, dereferencing, and assignment will look like this: Gamma \mid - t1 : T1

```
(T_Ref) Gamma |- ref t1 : Ref T1
Gamma |- t1 : Ref T11

(T_Deref) Gamma |- !t1 : T11
Gamma |- t1 : Ref T11 Gamma |- t2 : T11
```

 (T_Assign) Gamma |-t1:=t2: Unit The rule for locations will require a bit more machinery, and this will motivate some changes to the other rules; we'll come back to this later.

Values and Substitution

Besides abstractions and numbers, we have two new types of values: the unit value, and locations.

```
Inductive value : tm \rightarrow Prop := |v_abs : \forall x \ T \ t,
value (tabs x \ T \ t)
|v_abt : \forall n,
```

```
value (tnat n)
   | v_unit :
        value tunit
   | v_{loc} : \forall l,
        value (tloc l).
Hint Constructors value.
    Extending substitution to handle the new syntax of terms is straightforward.
Fixpoint subst (x:id) (s:tm) (t:tm) : tm :=
  match t with
   | tvar x' \Rightarrow
         if beq_id x x' then s else t
   | tapp t1 t2 \Rightarrow
        tapp (subst x \ s \ t1) (subst x \ s \ t2)
   | tabs x' T t1 \Rightarrow
        if beq_id x x' then t else tabs x' T (subst x s t1)
   \mid tnat n \Rightarrow
        t
   | tsucc t1 \Rightarrow
        tsucc (subst x \ s \ t1)
   | tpred t1 \Rightarrow
        tpred (subst x \ s \ t1)
   | tmult t1 t2 \Rightarrow
        tmult (subst x \ s \ t1) (subst x \ s \ t2)
   | tif0 t1 t2 t3 \Rightarrow
        tif0 (subst x \ s \ t1) (subst x \ s \ t2) (subst x \ s \ t3)
   \mid tunit \Rightarrow
        t
   | \text{ tref } t1 \Rightarrow
        tref (subst x \ s \ t1)
   | tderef t1 \Rightarrow
        tderef (subst x \ s \ t1)
   | tassign t1 t2 \Rightarrow
        tassign (subst x \ s \ t1) (subst x \ s \ t2)
   | tloc _{-} \Rightarrow
        t
   end.
Notation "'[' x ':=' s ']' t" := (subst x \ s \ t) (at level 20).
```

25.2 Pragmatics

25.2.1 Side Effects and Sequencing

The fact that the result of an assignment expression is the trivial value *unit* allows us to use a nice abbreviation for *sequencing*. For example, we can write

```
r:=succ(!r); !r
```

as an abbreviation for

```
(\x:Unit. !r) (r := succ(!r)).
```

This has the effect of evaluating two expressions in order and returning the value of the second. Restricting the type of the first expression to *Unit* helps the typechecker to catch some silly errors by permitting us to throw away the first value only if it is really guaranteed to be trivial.

Notice that, if the second expression is also an assignment, then the type of the whole sequence will be Unit, so we can validly place it to the left of another; to build longer sequences of assignments:

```
r:=succ(!r); r:=succ(!r); r:=succ(!r); !r
```

Formally, we introduce sequencing as a "derived form" tseq that expands into an abstraction and an application.

```
Definition tseq t1 t2 := tapp (tabs (Id 0) TUnit t2) t1.
```

25.2.2 References and Aliasing

It is important to bear in mind the difference between the *reference* that is bound to r and the *cell* in the store that is pointed to by this reference.

If we make a copy of r, for example by binding its value to another variable s, what gets copied is only the *reference*, not the contents of the cell itself.

For example, after evaluating

```
let r = ref 5 in
let s = r in
s := 82;
(!r)+1
```

the cell referenced by r will contain the value 82, while the result of the whole expression will be 83. The references r and s are said to be aliases for the same cell.

The possibility of aliasing can make programs with references quite tricky to reason about. For example, the expression

```
r := 5; r := !s
```

assigns 5 to r and then immediately overwrites it with s's current value; this has exactly the same effect as the single assignment

```
r := !s
```

unless we happen to do it in a context where r and s are aliases for the same cell!

25.2.3 Shared State

Of course, aliasing is also a large part of what makes references useful. In particular, it allows us to set up "implicit communication channels" – shared state – between different parts of a program. For example, suppose we define a reference cell and two functions that manipulate its contents:

```
let c = ref 0 in
let incc = \_:Unit. (c := succ (!c); !c) in
let decc = \_:Unit. (c := pred (!c); !c) in
```

Note that, since their argument types are Unit, the abstractions in the definitions of incc and decc are not providing any useful information to the bodies of the functions (using the wildcard $_$ as the name of the bound variable is a reminder of this). Instead, their purpose is to "slow down" the execution of the function bodies: since function abstractions are values, the two lets are executed simply by binding these functions to the names incc and decc, rather than by actually incrementing or decrementing c. Later, each call to one of these functions results in its body being executed once and performing the appropriate mutation on c. Such functions are often called thunks.

In the context of these declarations, calling incc results in changes to c that can be observed by calling decc. For example, if we replace the ... with $(incc\ unit;\ incc\ unit;\ decc\ unit)$, the result of the whole program will be 1.

25.2.4 Objects

We can go a step further and write a function that creates c, incc, and decc, packages incc and decc together into a record, and returns this record:

```
newcounter =
  \_:Unit.
  let c = ref 0 in
  let incc = \_:Unit. (c := succ (!c); !c) in
  let decc = \_:Unit. (c := pred (!c); !c) in
  {i=incc, d=decc}
```

Now, each time we call *newcounter*, we get a new record of functions that share access to the same storage cell c. The caller of *newcounter* can't get at this storage cell directly, but can affect it indirectly by calling the two functions. In other words, we've created a simple form of *object*.

```
let c1 = newcounter unit in
let c2 = newcounter unit in
// Note that we've allocated two separate storage cells now!
let r1 = c1.i unit in
let r2 = c2.i unit in
r2 // yields 1, not 2!
```

Exercise: 1 star (store_draw) Draw (on paper) the contents of the store at the point in execution where the first two lets have finished and the third one is about to begin.

25.2.5 References to Compound Types

A reference cell need not contain just a number: the primitives we've defined above allow us to create references to values of any type, including functions. For example, we can use references to functions to give a (not very efficient) implementation of arrays of numbers, as follows. Write NatArray for the type $Ref(Nat \rightarrow Nat)$.

Recall the equal function from the MoreStlc chapter:

```
equal =
  fix
  (\eq:Nat->Nat->Bool.
   \m:Nat. \n:Nat.
    if m=0 then iszero n
    else if n=0 then false
    else eq (pred m) (pred n))
```

Now, to build a new array, we allocate a reference cell and fill it with a function that, when given an index, always returns 0.

```
newarray = \_:Unit. ref (\n:Nat.0)
```

To look up an element of an array, we simply apply the function to the desired index.

```
lookup = \a:NatArray. \n:Nat. (!a) n
```

The interesting part of the encoding is the *update* function. It takes an array, an index, and a new value to be stored at that index, and does its job by creating (and storing in the reference) a new function that, when it is asked for the value at this very index, returns the new value that was given to *update*, and on all other indices passes the lookup to the function that was previously stored in the reference.

References to values containing other references can also be very useful, allowing us to define data structures such as mutable lists and trees.

Exercise: 2 stars (compact_update) If we defined update more compactly like this

25.2.6 Null References

There is one more difference between our references and C-style mutable variables: in C-like languages, variables holding pointers into the heap may sometimes have the value *NULL*. Dereferencing such a "null pointer" is an error, and results in an exception (Java) or in termination of the program (C).

Null pointers cause significant trouble in C-like languages: the fact that any pointer might be null means that any dereference operation in the program can potentially fail. However, even in ML-like languages, there are occasionally situations where we may or may not have a valid pointer in our hands. Fortunately, there is no need to extend the basic mechanisms of references to achieve this: the sum types introduced in the *MoreStlc* chapter already give us what we need.

First, we can use sums to build an analog of the *option* types introduced in the *Lists* chapter. Define $Option\ T$ to be an abbreviation for $Unit\ +\ T$.

Then a "nullable reference to a T" is simply an element of the type $Option\ (Ref\ T)$.

25.2.7 Garbage Collection

A last issue that we should mention before we move on with formalizing references is storage de-allocation. We have not provided any primitives for freeing reference cells when they are no longer needed. Instead, like many modern languages (including ML and Java) we rely on the run-time system to perform garbage collection, collecting and reusing cells that can no longer be reached by the program.

This is *not* just a question of taste in language design: it is extremely difficult to achieve type safety in the presence of an explicit deallocation operation. The reason for this is the familiar dangling reference problem: we allocate a cell holding a number, save a reference to it in some data structure, use it for a while, then deallocate it and allocate a new cell holding a boolean, possibly reusing the same storage. Now we can have two names for the same storage cell – one with type Ref Nat and the other with type Ref Bool.

Exercise: 1 star (type_safety_violation) Show how this can lead to a violation of type safety.

25.3 Operational Semantics

25.3.1 Locations

The most subtle aspect of the treatment of references appears when we consider how to formalize their operational behavior. One way to see why is to ask, "What should be the values of type $Ref\ T$?" The crucial observation that we need to take into account is that evaluating a ref operator should do something – namely, allocate some storage – and the result of the operation should be a reference to this storage.

What, then, is a reference?

The run-time store in most programming language implementations is essentially just a big array of bytes. The run-time system keeps track of which parts of this array are currently in use; when we need to allocate a new reference cell, we allocate a large enough segment from the free region of the store (4 bytes for integer cells, 8 bytes for cells storing *Floats*, etc.), mark it as being used, and return the index (typically, a 32- or 64-bit integer) of the start of the newly allocated region. These indices are references.

For present purposes, there is no need to be quite so concrete. We can think of the store as an array of values, rather than an array of bytes, abstracting away from the different sizes of the run-time representations of different values. A reference, then, is simply an index into the store. (If we like, we can even abstract away from the fact that these indices are numbers, but for purposes of formalization in Coq it is a bit more convenient to use numbers.) We'll use the word location instead of reference or pointer from now on to emphasize this abstract quality.

Treating locations abstractly in this way will prevent us from modeling the *pointer arithmetic* found in low-level languages such as C. This limitation is intentional. While pointer arithmetic is occasionally very useful, especially for implementing low-level services such as garbage collectors, it cannot be tracked by most type systems: knowing that location n in the store contains a *float* doesn't tell us anything useful about the type of location n+4. In C, pointer arithmetic is a notorious source of type safety violations.

25.3.2 Stores

Recall that, in the small-step operational semantics for IMP, the step relation needed to carry along an auxiliary state in addition to the program being executed. In the same way, once we have added reference cells to the STLC, our step relation must carry along a store to keep track of the contents of reference cells.

We could re-use the same functional representation we used for states in IMP, but for carrying out the proofs in this chapter it is actually more convenient to represent a store simply as a *list* of values. (The reason we couldn't use this representation before is that, in IMP, a program could modify any location at any time, so states had to be ready to map any variable to a value. However, in the STLC with references, the only way to create a reference cell is with $tref\ t1$, which puts the value of t1 in a new reference cell and evaluates to the location of the newly created reference cell. When evaluating such an expression, we can just add a new reference cell to the end of the list representing the store.)

```
Definition store := list tm.
```

We use $store_lookup$ n st to retrieve the value of the reference cell at location n in the store st. Note that we must give a default value to nth in case we try looking up an index which is too large. (In fact, we will never actually do this, but proving it will of course require some work!)

```
Definition store_lookup (n:nat) (st:store) :=
  nth n st tunit.
    To add a new reference cell to the store, we use snoc.
Fixpoint snoc \{A: \mathsf{Type}\}\ (l: \mathsf{list}\ A)\ (x:A): \mathsf{list}\ A:=
  \mathtt{match}\ l with
  | \mathsf{nil} \Rightarrow x :: \mathsf{nil}
  |h::t\Rightarrow h::snoc\ t\ x
  end.
    We will need some boring lemmas about snoc. The proofs are routine inductions.
Lemma length_snoc : \forall A (l: list A) x,
  length (snoc l(x) = S (length l).
Proof.
  induction l; intros; | auto | simpl; rewrite IHl; auto |. Qed.
Lemma nth_lt_snoc: \forall A (l:list A) x d n,
  n < \text{length } l \rightarrow
  nth n \mid d = nth n \text{ (snoc } l \mid x) \mid d.
Proof.
  induction l as [a \ l']; intros; try solve by inversion.
  Case "l = a :: l'".
     destruct n; auto.
     simpl. apply IHl'.
     simpl in H. apply t_S_n in H. assumption.
Qed.
Lemma nth_eq_snoc : \forall A (l: list A) x d,
  nth (length l) (snoc l(x)) d = x.
Proof.
  induction l; intros; | auto | simpl; rewrite IHl; auto |.
Qed.
```

To update the store, we use the replace function, which replaces the contents of a cell at a particular index.

```
Fixpoint replace \{A: \mathsf{Type}\}\ (n:\mathsf{nat})\ (x:A)\ (l:\mathsf{list}\ A): \mathsf{list}\ A:=
  {\tt match}\ l\ {\tt with}
  | nil \Rightarrow nil
  |h::t\Rightarrow
     {\tt match}\ n\ {\tt with}
     | 0 \Rightarrow x :: t
     | S n' \Rightarrow h :: replace n' x t
     end
  end.
    Of course, we also need some boring lemmas about replace, which are also fairly straight-
forward to prove.
Lemma replace_nil : \forall A \ n \ (x:A),
  replace n \times nil = nil.
Proof.
  destruct n; auto.
Qed.
Lemma length_replace : \forall A \ n \ x \ (l: list \ A),
  length (replace n \times l) = length l.
Proof with auto.
  intros A n x l. generalize dependent n.
  induction l; intros n.
     destruct n...
     destruct n...
        simpl. rewrite IHl...
Qed.
Lemma lookup_replace_eq : \forall l t st,
  l < length st \rightarrow
  store_lookup l (replace l t st) = t.
Proof with auto.
  intros l t st.
  unfold store_lookup.
  generalize dependent l.
  induction st as [t' st']; intros l Hlen.
  Case "st = []".
    inversion Hlen.
   Case "st = t' :: st'".
     destruct l; simpl...
     apply IHst'. simpl in Hlen. omega.
Qed.
```

```
Lemma lookup_replace_neq : \forall l1 l2 t st,
  l1 \neq l2 \rightarrow
  store_lookup l1 (replace l2 t st) = store_lookup l1 st.
Proof with auto.
  unfold store_lookup.
  induction l1 as [l1']; intros l2 t st Hneq.
  Case "11 = 0".
     destruct st.
     SCase \text{ "st} = []". rewrite replace_nil...
     SCase "st = \bot". destruct l2... contradict Hneg...
  Case "11 = S 11".
     destruct st as [t2 \ st2].
     SCase "st = []". destruct l2...
     SCase "st = t2 :: st2".
       destruct l2...
       simpl; apply IHl1'...
Qed.
```

25.3.3 Reduction

Next, we need to extend our operational semantics to take stores into account. Since the result of evaluating an expression will in general depend on the contents of the store in which it is evaluated, the evaluation rules should take not just a term but also a store as argument. Furthermore, since the evaluation of a term may cause side effects on the store that may affect the evaluation of other terms in the future, the evaluation rules need to return a new store. Thus, the shape of the single-step evaluation relation changes from t ==> t' to t / st ==> t' / st', where st and st' are the starting and ending states of the store.

To carry through this change, we first need to augment all of our existing evaluation rules with stores: value v2

```
 \begin{array}{l} {\rm (ST\_AppAbs)} \ (\x:T.t12) \ v2 \ / \ st ==> x:=v2t12 \ / \ st \\ {\rm t1 \ / \ st \ ==> t1' \ / \ st'} \\ {\rm (ST\_App1) \ t1 \ t2 \ / \ st \ ==> t1' \ t2 \ / \ st'} \\ {\rm value \ v1 \ t2 \ / \ st \ ==> t2' \ / \ st'} \\ \end{array}
```

 (ST_App2) v1 t2 / st ==> v1 t2' / st' Note that the first rule here returns the store unchanged: function application, in itself, has no side effects. The other two rules simply propagate side effects from premise to conclusion.

Now, the result of evaluating a *ref* expression will be a fresh location; this is why we included locations in the syntax of terms and in the set of values.

It is crucial to note that making this extension to the syntax of terms does not mean that we intend *programmers* to write terms involving explicit, concrete locations: such terms will

arise only as intermediate results of evaluation. This may initially seem odd, but really it follows naturally from our design decision to represent the result of every evaluation step by a modified term. If we had chosen a more "machine-like" model for evaluation, e.g. with an explicit stack to contain values of bound identifiers, then the idea of adding locations to the set of allowed values would probably seem more obvious.

In terms of this expanded syntax, we can state evaluation rules for the new constructs that manipulate locations and the store. First, to evaluate a dereferencing expression !t1, we must first reduce t1 until it becomes a value: t1 / st ==> t1' / st'

(ST_Deref) !t1 / st ==> !t1' / st' Once t1 has finished reducing, we should have an expression of the form !l, where l is some location. (A term that attempts to dereference any other sort of value, such as a function or unit, is erroneous, as is a term that tries to derefence a location that is larger than the size |st| of the currently allocated store; the evaluation rules simply get stuck in this case. The type safety properties that we'll establish below assure us that well-typed terms will never misbehave in this way.) 1 < |st|

```
(ST_DerefLoc) !(loc l) / st ==> lookup l st / st
```

Next, to evaluate an assignment expression t1:=t2, we must first evaluate t1 until it becomes a value (a location), and then evaluate t2 until it becomes a value (of any sort): t1 / st =>> t1' / st'

```
(ST_Assign1) t1 := t2 / st ==> t1' := t2 / st'
t2 / st ==> t2' / st'
```

(ST_Assign2) v1 := t2 / st ==> v1 := t2' / st' Once we have finished with t1 and t2, we have an expression of the form l:=v2, which we execute by updating the store to make location l contain v2: 1 < |st|

(ST_Assign) loc l := v2 / st ==> unit / l := v2st The notation [l := v2]st means "the store that maps l to v2 and maps all other locations to the same thing as st." Note that the term resulting from this evaluation step is just unit; the interesting result is the updated store.)

Finally, to evaluate an expression of the form $ref\ t1$, we first evaluate t1 until it becomes a value: t1 / st ==> t1' / st'

(ST_Ref) ref t1 / st ==> ref t1' / st' Then, to evaluate the *ref* itself, we choose a fresh location at the end of the current store – i.e., location |st| – and yield a new store that extends st with the new value v1.

(ST_RefValue) ref v1 / st ==> loc |st| / st,v1 The value resulting from this step is the newly allocated location itself. (Formally, st,v1 means $snoc\ st\ v1$.)

Note that these evaluation rules do not perform any kind of garbage collection: we simply allow the store to keep growing without bound as evaluation proceeds. This does

not affect the correctness of the results of evaluation (after all, the definition of "garbage" is precisely parts of the store that are no longer reachable and so cannot play any further role in evaluation), but it means that a naive implementation of our evaluator might sometimes run out of memory where a more sophisticated evaluator would be able to continue by reusing locations whose contents have become garbage.

Formally...

```
Reserved Notation "t1 '/' st1 '==>' t2 '/' st2"
  (at level 40, st1 at level 39, t2 at level 39).

25.4 Typing

Our contexts for free variables will be exactly the same as for the STLC, partial maps from identifiers to types.

Definition context := partial_map ty.

25.4.1 Store typings

Having extended our syntax and evaluation rules to accommodate references, our last job is to write down typing rules for the new constructs – and, of course, to check that they are sound. Naturally, the key question is, "What is the type of a location?"

First of all, notice that we do *not* need to answer this question for purposes of type-checking the terms that programmers actually write. Concrete location constants arise only in terms that are the intermediate results of evaluation; they are not in the language that programmers write. So we only need to determine the type of a location when we're in the middle of an evaluation sequence, e.g. trying to apply the progress or preservation lemmas. Thus, even though we normally think of typing as a *static* program property, it makes sense for the typing of locations to depend on the *dynamic* progress of the program too.

As a first try, note that when we evaluate a term containing concrete locations, the type of the result depends on the contents of the store that we start with. For example, if we evaluate the term $!(loc\ 1)$ in the store $[unit,\ unit]$, the result is unit; if we evaluate the same term in the store $[unit,\ x:Unit.x]$, the result is x:Unit.x. With respect to the former store, the location 1 has type Unit, and with respect to the latter it has type $Unit \rightarrow Unit$. This observation leads us immediately to a first attempt at a typing rule for locations: Gamma |- lookup 1 st : T1

Gamma \mid - loc l: Ref T1 That is, to find the type of a location l, we look up the current contents of l in the store and calculate the type T1 of the contents. The type of the location is then $Ref\ T1$.

Having begun in this way, we need to go a little further to reach a consistent state. In effect, by making the type of a term depend on the store, we have changed the typing relation from a three-place relation (between contexts, terms, and types) to a four-place relation (between contexts, stores, terms, and types). Since the store is, intuitively, part of the context in which we calculate the type of a term, let's write this four-place relation with the store to the left of the turnstile: Gamma; $st \vdash t$: T. Our rule for typing references now has the form Gamma; $st \vdash l$ lookup l st: l

Gamma; st |- loc l : Ref T1 and all the rest of the typing rules in the system are extended similarly with stores. The other rules do not need to do anything interesting with their stores – just pass them from premise to conclusion.

However, there are two problems with this rule. First, typechecking is rather inefficient, since calculating the type of a location l involves calculating the type of the current contents v of l. If l appears many times in a term t, we will re-calculate the type of v many times in the course of constructing a typing derivation for t. Worse, if v itself contains locations, then we will have to recalculate their types each time they appear.

Second, the proposed typing rule for locations may not allow us to derive anything at all, if the store contains a *cycle*. For example, there is no finite typing derivation for the location 0 with respect to this store:

```
[x:Nat. (!(loc 1)) x, x:Nat. (!(loc 0)) x]
```

Exercise: 2 stars (cyclic_store) Can you find a term whose evaluation will create this particular cyclic store?

Both of these problems arise from the fact that our proposed typing rule for locations requires us to recalculate the type of a location every time we mention it in a term. But this, intuitively, should not be necessary. After all, when a location is first created, we know the type of the initial value that we are storing into it. Suppose we are willing to enforce the invariant that the type of the value contained in a given location never changes; that is, although we may later store other values into this location, those other values will always have the same type as the initial one. In other words, we always have in mind a single, definite type for every location in the store, which is fixed when the location is allocated. Then these intended types can be collected together as a store typing —a finite function mapping locations to types.

As usual, this *conservative* typing restriction on allowed updates means that we will rule out as ill-typed some programs that could evaluate perfectly well without getting stuck.

Just like we did for stores, we will represent a store type simply as a list of types: the type at index i records the type of the value stored in cell i.

```
Definition store_ty := list ty.
```

The store_Tlookup function retrieves the type at a particular index.

```
Definition store_Tlookup (n:nat) (ST:store_ty) := nth \ n \ ST TUnit.
```

Suppose we are given a store typing ST describing the store st in which some term t will be evaluated. Then we can use ST to calculate the type of the result of t without ever looking directly at st. For example, if ST is $[Unit, Unit \rightarrow Unit]$, then we may immediately infer that $!(loc\ 1)$ has type $Unit \rightarrow Unit$. More generally, the typing rule for locations can be reformulated in terms of store typings like this: 1 < |ST|

That is, as long as l is a valid location (it is less than the length of ST), we can compute the type of l just by looking it up in ST. Typing is again a four-place relation, but it is parameterized on a store typing rather than a concrete store. The rest of the typing rules are analogously augmented with store typings.

25.4.2 The Typing Relation

We can now give the typing relation for the STLC with references. Here, again, are the rules we're adding to the base STLC (with numbers and Unit):

```
l < |ST|
```

```
(T_Loc) Gamma; ST |- loc l : Ref (lookup l ST)
    Gamma; ST \mid -t1 : T1
(T_Ref) Gamma; ST |- ref t1 : Ref T1
    Gamma; ST |- t1 : Ref T11
 (T_Deref) Gamma; ST \mid -!t1 : T11
    Gamma; ST |- t1 : Ref T11 Gamma; ST |- t2 : T11
 (T_Assign) Gamma; ST \mid -t1 := t2 : Unit
Inductive has\_type: context \rightarrow store_ty \rightarrow tm \rightarrow ty \rightarrow Prop :=
  | T_{Var} : \forall Gamma \ ST \ x \ T
         Gamma \ x = Some \ T \rightarrow
        has_type Gamma \ ST (tvar x) T
   \mid \mathsf{T}_{-}\mathsf{Abs} : \forall \ Gamma \ ST \ x \ T11 \ T12 \ t12,
        has_type (extend Gamma \ x \ T11) ST \ t12 \ T12 \rightarrow
        has_type Gamma \ ST \ (tabs \ x \ T11 \ t12) \ (TArrow \ T11 \ T12)
  \mid \mathsf{T}_{-}\mathsf{App} : \forall T1 \ T2 \ Gamma \ ST \ t1 \ t2,
        has_type Gamma\ ST\ t1\ (TArrow\ T1\ T2) \rightarrow
        has_type Gamma\ ST\ t2\ T1\ 	o
        has_type Gamma \ ST \ (tapp \ t1 \ t2) \ T2
   | \mathsf{T}_{-}\mathsf{Nat} : \forall \ Gamma \ ST \ n,
        has\_type \ Gamma \ ST \ (tnat \ n) \ TNat
  \mid \mathsf{T}_{-}\mathsf{Succ} : \forall \ Gamma \ ST \ t1,
        has_type Gamma \ ST \ t1 \ \mathsf{TNat} \to
        has\_type \ Gamma \ ST \ (tsucc \ t1) \ TNat
  \mid \mathsf{T}_{-}\mathsf{Pred} : \forall \ \textit{Gamma ST t1},
        has_type Gamma\ ST\ t1\ \mathsf{TNat} \to
        has_type Gamma \ ST \ (tpred \ t1) \ TNat
   | T_Mult : \forall Gamma \ ST \ t1 \ t2,
        has_type Gamma\ ST\ t1\ \mathsf{TNat} \to
```

```
has_type Gamma\ ST\ t2\ \mathsf{TNat} \to

  | T_Deref : \forall Gamma \ ST \ t1 \ T11,
       has_type Gamma\ ST\ t1\ (\mathsf{TRef}\ T11) \to
       has_type Gamma \ ST (tderef t1) T11
  \mid T_{-}Assign : \forall Gamma \ ST \ t1 \ t2 \ T11,
       has_type Gamma\ ST\ t1\ (\mathsf{TRef}\ T11) \to
       has_type Gamma\ ST\ t2\ T11\ 	o
       has_type Gamma \ ST (tassign t1 \ t2) TUnit.
Hint Constructors has_type.
Tactic Notation "has_type_cases" tactic(first) ident(c) :=
  first:
  [ Case_aux c "T_Var" | Case_aux c "T_Abs" | Case_aux c "T_App"
    Case_aux c "T_Nat" | Case_aux c "T_Succ" | Case_aux c "T_Pred"
    Case_aux c "T_Mult" | Case_aux c "T_If0"
    Case_aux c "T_Unit" | Case_aux c "T_Loc"
    Case_aux c "T_Ref" | Case_aux c "T_Deref"
    Case\_aux \ c \ "T\_Assign" ].
```

Of course, these typing rules will accurately predict the results of evaluation only if the concrete store used during evaluation actually conforms to the store typing that we assume for purposes of typechecking. This proviso exactly parallels the situation with free variables in the STLC: the substitution lemma promises us that, if $Gamma \vdash t : T$, then we can replace the free variables in t with values of the types listed in Gamma to obtain a closed term of type T, which, by the type preservation theorem will evaluate to a final result of type T if it yields any result at all. (We will see later how to formalize an analogous intuition for stores and store typings.)

However, for purposes of typechecking the terms that programmers actually write, we do not need to do anything tricky to guess what store typing we should use. Recall that concrete location constants arise only in terms that are the intermediate results of evaluation;

they are not in the language that programmers write. Thus, we can simply typecheck the programmer's terms with respect to the *empty* store typing. As evaluation proceeds and new locations are created, we will always be able to see how to extend the store typing by looking at the type of the initial values being placed in newly allocated cells; this intuition is formalized in the statement of the type preservation theorem below.

25.5 Properties

Our final task is to check that standard type safety properties continue to hold for the STLC with references. The progress theorem ("well-typed terms are not stuck") can be stated and proved almost as for the STLC; we just need to add a few straightforward cases to the proof, dealing with the new constructs. The preservation theorem is a bit more interesting, so let's look at it first.

25.5.1 Well-Typed Stores

Since we have extended both the evaluation relation (with initial and final stores) and the typing relation (with a store typing), we need to change the statement of preservation to include these parameters. Clearly, though, we cannot just add stores and store typings without saying anything about how they are related:

```
Theorem preservation_wrong1 : \forall ST T t st t' st', has_type empty ST t T \rightarrow t / st ==> t' / st' \rightarrow has_type empty ST t' T. Admitted.
```

If we typecheck with respect to some set of assumptions about the types of the values in the store and then evaluate with respect to a store that violates these assumptions, the result will be disaster. We say that a store st is well typed with respect a store typing ST if the term at each location l in st has the type at location l in ST. Since only closed terms ever get stored in locations (why?), it suffices to type them in the empty context. The following definition of $store_well_typed$ formalizes this.

```
 \begin{array}{l} {\sf Definition\ store\_well\_typed\ }(ST{:}{\sf store\_ty})\ (st{:}{\sf store}) := \\ {\sf length\ }ST = {\sf length\ }st\ \land \\ (\forall\ l,\ l < {\sf length\ }st \to \\ {\sf\ has\_type\ empty\ }ST\ ({\sf store\_lookup\ }l\ st)\ ({\sf store\_Tlookup\ }l\ ST)). \end{array}
```

Informally, we will write $ST \vdash st$ for $store_well_typed$ ST st.

Intuitively, a store st is consistent with a store typing ST if every value in the store has the type predicted by the store typing. (The only subtle point is the fact that, when typing the values in the store, we supply the very same store typing to the typing relation! This allows us to type circular stores.)

Exercise: 2 stars (store_not_unique) Can you find a store st, and two different store typings ST1 and ST2 such that both $ST1 \vdash st$ and $ST2 \vdash st$?

We can now state something closer to the desired preservation property:

```
Theorem preservation_wrong2 : \forall ST T t st t' st', has_type empty ST t T \rightarrow t / st ==> t' / st' \rightarrow store_well_typed ST st \rightarrow has_type empty ST t' T. Admitted.
```

This statement is fine for all of the evaluation rules except the allocation rule $ST_RefValue$. The problem is that this rule yields a store with a larger domain than the initial store, which falsifies the conclusion of the above statement: if st' includes a binding for a fresh location l, then l cannot be in the domain of ST, and it will not be the case that t' (which definitely mentions l) is typable under ST.

25.5.2 Extending Store Typings

Evidently, since the store can increase in size during evaluation, we need to allow the store typing to grow as well. This motivates the following definition. We say that the store type ST' extends ST if ST' is just ST with some new types added to the end.

```
\begin{array}{l} \textbf{Inductive extends}: \textbf{store\_ty} \rightarrow \textbf{store\_ty} \rightarrow \textbf{Prop}:=\\ | \ \textbf{extends\_nil}: \ \forall \ ST',\\ & \ \textbf{extends} \ ST' \ \textbf{nil}\\ | \ \textbf{extends\_cons}: \ \forall \ x \ ST' \ ST,\\ & \ \textbf{extends} \ ST' \ ST \rightarrow\\ & \ \textbf{extends} \ (x \colon : ST') \ (x \colon : ST). \end{array}
```

Hint Constructors extends.

We'll need a few technical lemmas about extended contexts.

First, looking up a type in an extended store typing yields the same result as in the original:

```
Lemma extends_lookup: \forall \ l \ ST \ ST', l < length \ ST \rightarrow extends ST' \ ST \rightarrow store_Tlookup l \ ST' = store_Tlookup \ l \ ST.
Proof with auto.
intros l \ ST \ ST' \ Hlen \ H.
generalize dependent ST'. generalize dependent l.
induction ST as [|a \ ST2]; intros l \ Hlen \ ST' \ HST'.
Case "nil". inversion Hlen.
Case "cons". unfold store_Tlookup in *.
```

```
destruct ST'.
     SCase "ST' = nil". inversion HST'.
    SCase "ST' = a' :: ST'2".
       inversion HST'; subst.
       destruct l as [|l'|].
       SSCase "l = 0"...
       SSCase "l = S l". simpl. apply IHST2...
         simpl in Hlen; omega.
Qed.
   Next, if ST' extends ST, the length of ST' is at least that of ST.
Lemma length_extends : \forall l ST ST',
  l < \text{length } ST \rightarrow
  extends ST' ST \rightarrow
  l < length ST'.
Proof with eauto.
  intros. generalize dependent l. induction H0; intros l Hlen.
    inversion Hlen.
    simpl in *.
    destruct l; try omega.
       apply It_n_S. apply IHextends. omega.
Qed.
   Finally, snoc ST T extends ST, and extends is reflexive.
Lemma extends_snoc : \forall ST T,
  extends (snoc ST T) ST.
Proof with auto.
  induction ST; intros T...
  simpl...
Qed.
Lemma extends_refl : \forall ST,
  extends ST ST.
Proof.
  induction ST; auto.
Qed.
```

25.5.3 Preservation, Finally

We can now give the final, correct statement of the type preservation property:

```
Definition preservation_theorem := \forall \ ST \ t \ t' \ T \ st \ st', has_type empty ST \ t \ T \rightarrow store_well_typed ST \ st \rightarrow t \ / \ st ==> t' \ / \ st' \rightarrow
```

```
\exists ST', (extends ST' ST \land has_type empty ST' t' T \land store_well_typed ST' st').
```

Note that the preservation theorem merely asserts that there is *some* store typing ST' extending ST (i.e., agreeing with ST on the values of all the old locations) such that the new term t' is well typed with respect to ST'; it does not tell us exactly what ST' is. It is intuitively clear, of course, that ST' is either ST or else it is exactly $snoc\ ST\ T1$, where T1 is the type of the value v1 in the extended store $snoc\ st\ v1$, but stating this explicitly would complicate the statement of the theorem without actually making it any more useful: the weaker version above is already in the right form (because its conclusion implies its hypothesis) to "turn the crank" repeatedly and conclude that every sequence of evaluation steps preserves well-typedness. Combining this with the progress property, we obtain the usual guarantee that "well-typed programs never go wrong."

In order to prove this, we'll need a few lemmas, as usual.

25.5.4 Substitution lemma

First, we need an easy extension of the standard substitution lemma, along with the same machinery about context invariance that we used in the proof of the substitution lemma for the STLC.

```
Inductive appears_free_in : id \rightarrow tm \rightarrow Prop :=
  | afi_var : \forall x,
        appears_free_in x (tvar x)
  | afi_app1 : \forall x t1 t2,

25.5.5 Assignment Preserves Store Typing

Next, we must show that replacing the contents of a cell in the store with a new value of appropriate type does not change the overall type of the store. (This is needed for the $ST_-Assign$ rule.)

```
Lemma assign_pres_store_typing : \forall \ ST \ st \ l \ t, l < \mathsf{length} \ st \to \mathsf{store}\_\mathsf{well}\_\mathsf{typed} \ ST \ st \to \mathsf{has}\_\mathsf{type} \ \mathsf{empty} \ ST \ t \ (\mathsf{store}\_\mathsf{Tlookup} \ l \ ST) \to \mathsf{store}\_\mathsf{well}\_\mathsf{typed} \ ST \ (\mathsf{replace} \ l \ t \ st). Proof with auto.
```

25.5.6 Weakening for Stores

Finally, we need a lemma on store typings, stating that, if a store typing is extended with a new location, the extended one still allows us to assign the same types to the same terms as the original.

(The lemma is called *store_weakening* because it resembles the "weakening" lemmas found in proof theory, which show that adding a new assumption to some logical theory does not decrease the set of provable theorems.)

```
Lemma store_weakening : \forall Gamma ST ST' t T, extends ST' ST \rightarrow has_type Gamma ST t T \rightarrow has_type Gamma ST' t T.

Proof with eauto.

intros. has_type_cases (induction H0) Case; eauto. Case "T_Loc".

erewrite \leftarrow extends_lookup...

apply T_Loc.

eapply length_extends...

Qed.
```

We can use the $store_weakening$ lemma to prove that if a store is well typed with respect to a store typing, then the store extended with a new term t will still be well typed with respect to the store typing extended with t's type.

```
Lemma store_well_typed_snoc : \forall ST \ st \ t1 \ T1, store_well_typed ST \ st \rightarrow has_type empty ST \ t1 \ T1 \rightarrow store_well_typed (snoc ST \ T1) (snoc st \ t1). Proof with auto.
```

```

25.6 References and Nontermination

Section RefsAndNontermination.

Import Example Variables.

We know that the simply typed lambda calculus is *normalizing*, that is, every well-typed term can be reduced to a value in a finite number of steps. What about STLC + references? Surprisingly, adding references causes us to lose the normalization property: there exist well-typed terms in the STLC + references which can continue to reduce forever, without ever reaching a normal form!

How can we construct such a term? The main idea is to make a function which calls itself. We first make a function which calls another function stored in a reference cell; the trick is that we then smuggle in a reference to itself!

```
(\r:Ref (Unit -> Unit).
    r := (\x:Unit.(!r) unit); (!r) unit)
(ref (\x:Unit.unit))
```

First, ref (\x:Unit.unit) creates a reference to a cell of type $Unit \to Unit$. We then pass this reference as the argument to a function which binds it to the name r, and assigns to it the function (\x:Unit.(!r) unit) – that is, the function which ignores its argument and calls the function stored in r on the argument unit; but of course, that function is itself! To get the ball rolling we finally execute this function with (!r) unit.

This term is well typed:

```
Lemma loop_typeable : ∃ T, has_type empty [] loop T.

Proof with eauto.

eexists. unfold loop. unfold loop_fun.

eapply T_App...

eapply T_Abs...

eapply T_Abs...

eapply T_Abs. eapply T_App. eapply T_Deref. eapply T_Var.

unfold extend. simpl. reflexivity. auto.

eapply T_Assign.

eapply T_Var. unfold extend. simpl. reflexivity.

eapply T_Abs.

eapply T_App...

eapply T_App...

eapply T_Deref. eapply T_Var. reflexivity.

Qed.
```

To show formally that the term diverges, we first define the $step_closure$ of the single-step reduction relation, written ==>+. This is just like the reflexive step closure of single-step reduction (which we're been writing ==>*), except that it is not reflexive: t==>+t' means that t can reach t' by one or more steps of reduction.

```
Inductive step\_closure \{X:Type\}\ (R: relation \ X): X \to X \to Prop:= | sc\_one: \forall (x \ y : X), R \ x \ y \to step\_closure R \ x \ y | sc\_step: \forall (x \ y \ z : X), R \ x \ y \to step\_closure R \ y \ z \to step\_closure R \ x \ z.
Definition multistep1:= (step\_closure step).
Notation "t1'/' st'==>+' t2'/' st'":= (multistep1 (t1,st) (t2,st')) (at level 40, st at level 39, t2 at level 39).
```

Now, we can show that the expression loop reduces to the expression $!(loc\ 0)$ unit and the size-one store $[r:=(loc\ 0)]$ $loop_fun$.

As a convenience, we introduce a slight variant of the *normalize* tactic, called *reduce*, which tries solving the goal with *multi_refl* at each step, instead of waiting until the goal can't be reduced any more. Of course, the whole point is that *loop* doesn't normalize, so the old *normalize* tactic would just go into an infinite loop reducing it forever!

```
\begin{split} \text{Ltac } print\_goal := \text{match goal with} \vdash ?x \Rightarrow \text{idtac } x \text{ end.} \\ \text{Ltac } reduce := \\ \text{repeat } (print\_goal; \text{ eapply multi\_step }; \\ \text{[ (eauto 10; fail)} \mid (\text{instantiate}; \text{ compute)}]; \\ \text{try solve [apply multi\_refl]).} \\ \text{Lemma loop\_steps\_to\_loop\_fun }: \end{split}
```

```
loop / nil ==>*
  tapp (tderef (tloc 0)) tunit / cons ([r:=tloc 0]loop_fun) nil.
Proof with eauto.
  unfold loop.
  reduce.
Qed.
  Finally, the latter expression reduces in two steps to itself!
Lemma loop_fun_step_self:
  tapp (tderef (tloc 0)) tunit / cons ([r:=tloc 0]loop_fun) nil ==>+
  tapp (tderef (tloc 0)) tunit / cons ([r:=tloc 0]loop_fun) nil.
Proof with eauto.
  unfold loop_fun; simpl.
  eapply sc_step. apply ST_App1...
  eapply sc_one. compute. apply ST_AppAbs...
Qed.
```

Exercise: 4 stars (factorial_ref) Use the above ideas to implement a factorial function in STLC with references. (There is no need to prove formally that it really behaves like the factorial. Just use the example below to make sure it gives the correct result when applied to the argument 4.)

```
Definition factorial : tm :=
    admit.

Lemma factorial_type : has_type empty nil factorial (TArrow TNat TNat).
Proof with eauto.
    Admitted.
```

If your definition is correct, you should be able to just uncomment the example below; the proof should be fully automatic using the *reduce* tactic.

25.7 Additional Exercises

Exercise: 5 stars, optional (garabage_collector) Challenge problem: modify our formalization to include an account of garbage collection, and prove that it satisfies whatever nice properties you can think to prove about it.

End RefsAndNontermination. End STLCRef.

Chapter 26

Library Sub

26.1 Sub: Subtyping

Require Export MoreStlc.

26.2 Concepts

We now turn to the study of *subtyping*, perhaps the most characteristic feature of the static type systems of recently designed programming languages and a key feature needed to support the object-oriented programming style.

26.2.1 A Motivating Example

Suppose we are writing a program involving two record types defined as follows:

```
Person = {name:String, age:Nat}
Student = {name:String, age:Nat, gpa:Nat}
```

In the simply typed lamdba-calculus with records, the term

```
(\r:Person. (r.age)+1) {name="Pat",age=21,gpa=1}
```

is not typable: it involves an application of a function that wants a one-field record to an argument that actually provides two fields, while the T_-App rule demands that the domain type of the function being applied must match the type of the argument precisely.

But this is silly: we're passing the function a *better* argument than it needs! The only thing the body of the function can possibly do with its record argument r is project the field age from it: nothing else is allowed by the type, and the presence or absence of an extra gpa field makes no difference at all. So, intuitively, it seems that this function should be applicable to any record value that has at least an age field.

Looking at the same thing from another point of view, a record with more fields is "at least as good in any context" as one with just a subset of these fields, in the sense that any value belonging to the longer record type can be used *safely* in any context expecting the shorter record type. If the context expects something with the shorter type but we actually give it something with the longer type, nothing bad will happen (formally, the program will not get stuck).

The general principle at work here is called *subtyping*. We say that "S is a subtype of T", informally written S <: T, if a value of type S can safely be used in any context where a value of type T is expected. The idea of subtyping applies not only to records, but to all of the type constructors in the language – functions, pairs, etc.

26.2.2 Subtyping and Object-Oriented Languages

Subtyping plays a fundamental role in many programming languages – in particular, it is closely related to the notion of *subclassing* in object-oriented languages.

An *object* in Java, C#, etc. can be thought of as a record, some of whose fields are functions ("methods") and some of whose fields are data values ("fields" or "instance variables"). Invoking a method m of an object o on some arguments a1..an consists of projecting out the m field of o and applying it to a1..an.

The type of an object can be given as either a *class* or an *interface*. Both of these provide a description of which methods and which data fields the object offers.

Classes and interfaces are related by the *subclass* and *subinterface* relations. An object belonging to a subclass (or subinterface) is required to provide all the methods and fields of one belonging to a superclass (or superinterface), plus possibly some more.

The fact that an object from a subclass (or sub-interface) can be used in place of one from a superclass (or super-interface) provides a degree of flexibility that is is extremely handy for organizing complex libraries. For example, a GUI toolkit like Java's Swing framework might define an abstract interface *Component* that collects together the common fields and methods of all objects having a graphical representation that can be displayed on the screen and that can interact with the user. Examples of such object would include the buttons, checkboxes, and scrollbars of a typical GUI. A method that relies only on this common interface can now be applied to any of these objects.

Of course, real object-oriented languages include many other features besides these. For example, fields can be updated. Fields and methods can be declared *private*. Classes also give *code* that is used when constructing objects and implementing their methods, and the code in subclasses cooperate with code in superclasses via *inheritance*. Classes can have static methods and fields, initializers, etc., etc.

To keep things simple here, we won't deal with any of these issues – in fact, we won't even talk any more about objects or classes. (There is a lot of discussion in *Types and Programming Languages*, if you are interested.) Instead, we'll study the core concepts behind the subclass / subinterface relation in the simplified setting of the STLC.

26.2.3 The Subsumption Rule

Our goal for this chapter is to add subtyping to the simply typed lambda-calculus (with some of the basic extensions from MoreStlc). This involves two steps:

- Defining a binary subtype relation between types.
- Enriching the typing relation to take subtyping into account.

The second step is actually very simple. We add just a single rule to the typing relation: the so-called $rule\ of\ subsumption$: Gamma |- t : S S <: T

(T_Sub) Gamma |- t : T This rule says, intuitively, that it is OK to "forget" some of what we know about a term. For example, we may know that t is a record with two fields (e.g., $S = \{x:A \rightarrow A, y:B \rightarrow B\}$), but choose to forget about one of the fields ($T = \{y:B \rightarrow B\}$) so that we can pass t to a function that requires just a single-field record.

26.2.4 The Subtype Relation

The first step – the definition of the relation S <: T – is where all the action is. Let's look at each of the clauses of its definition.

Structural Rules

To start off, we impose two "structural rules" that are independent of any particular type constructor: a rule of transitivity, which says intuitively that, if S is better than U and U is better than T, then S is better than T... S <: U U <: T

(S_Trans) S <: T ... and a rule of reflexivity, since any type T is always just as good as itself:

 $(S_Refl) T <: T$

Products

Now we consider the individual type constructors, one by one, beginning with product types. We consider one pair to be "better than" another if each of its components is. S1 <: T1 S2 <: T2

 $(S_Prod) S1*S2 <: T1*T2$

Arrows

Suppose we have two functions f and g with these types:

```
f : C -> Student
g : (C -> Person) -> D
```

That is, f is a function that yields a record of type Student, and g is a (higher-order) function that expects its (function) argument to yield a record of type Person. Also suppose, even though we haven't yet discussed subtyping for records, that Student is a subtype of Person. Then the application g f is safe even though their types do not match up precisely, because the only thing g can do with f is to apply it to some argument (of type C); the result will actually be a Student, while g will be expecting a Person, but this is safe because the only thing g can then do is to project out the two fields that it knows about (name and age), and these will certainly be among the fields that are present.

This example suggests that the subtyping rule for arrow types should say that two arrow types are in the subtype relation if their results are: S2 <: T2

(S_Arrow_Co) S1->S2 <: S1->T2 We can generalize this to allow the arguments of the two arrow types to be in the subtype relation as well: T1 <: S1 S2 <: T2

(S_Arrow) S1->S2 <: T1->T2 Notice that the argument types are subtypes "the other way round": in order to conclude that $S1 \rightarrow S2$ to be a subtype of $T1 \rightarrow T2$, it must be the case that T1 is a subtype of S1. The arrow constructor is said to be *contravariant* in its first argument and *covariant* in its second.

Here is an example that illustrates this:

```
f : Person -> C
g : (Student -> C) -> D
```

The application g f is safe, because the only thing the body of g can do with f is to apply it to some argument of type Student. Since f requires records having (at least) the fields of a Person, this will always work. So $Person \to C$ is a subtype of $Student \to C$ since Student is a subtype of Person.

The intuition is that, if we have a function f of type $S1 \rightarrow S2$, then we know that f accepts elements of type S1; clearly, f will also accept elements of any subtype T1 of S1. The type of f also tells us that it returns elements of type S2; we can also view these results belonging to any supertype T2 of S2. That is, any function f of type $S1 \rightarrow S2$ can also be viewed as having type $T1 \rightarrow T2$.

Exercise: 2 stars, recommended (arrow_sub_wrong) Suppose we had incorrectly defined subtyping as covariant on both the right and the left of arrow types: S1 <: T1 S2 <: T2

(S_Arrow_wrong) S1->S2 <: T1->T2 Give a concrete example of functions f and g with types...

```
f : Student -> Nat
g : (Person -> Nat) -> Nat
```

 \dots such that the application g f will get stuck during execution.

Records

What about subtyping for record types?

The basic intuition about subtyping for record types is that it is always safe to use a "bigger" record in place of a "smaller" one. That is, given a record type, adding extra fields will always result in a subtype. If some code is expecting a record with fields x and y, it is perfectly safe for it to receive a record with fields x, y, and z; the z field will simply be ignored. For example,

```
{name:String, age:Nat, gpa:Nat} <: {name:String, age:Nat}
{name:String, age:Nat} <: {name:String}
{name:String} <: {}</pre>
```

This is known as "width subtyping" for records.

We can also create a subtype of a record type by replacing the type of one of its fields with a subtype. If some code is expecting a record with a field x of type T, it will be happy with a record having a field x of type S as long as S is a subtype of T. For example,

```
{x:Student} <: {x:Person}</pre>
```

This is known as "depth subtyping".

Finally, although the fields of a record type are written in a particular order, the order does not really matter. For example,

```
{name:String,age:Nat} <: {age:Nat,name:String}</pre>
```

This is known as "permutation subtyping".

We could formalize these requirements in a single subtyping rule for records as follows: for each jk in j1..jn, exists ip in i1..im, such that jk=ip and Sp <: Tk

(S_Rcd) {i1:S1...im:Sm} <: {j1:T1...jn:Tn} That is, the record on the left should have all the field labels of the one on the right (and possibly more), while the types of the common fields should be in the subtype relation. However, this rule is rather heavy and hard to read. If we like, we can decompose it into three simpler rules, which can be combined using S_{-} Trans to achieve all the same effects.

First, adding fields to the end of a record type gives a subtype: n > m

(S_RcdWidth) {i1:T1...in:Tn} <: {i1:T1...im:Tm} We can use $S_RcdWidth$ to drop later fields of a multi-field record while keeping earlier fields, showing for example that {age:Nat,name:String} <: {name:String,age:Nat}.

Second, we can apply subtyping inside the components of a compound record type: S1 <: T1 ... Sn <: Tn

(S_RcdDepth) {i1:S1...in:Sn} <: {i1:T1...in:Tn} For example, we can use $S_RcdDepth$ and $S_RcdWidth$ together to show that $\{y:Student, x:Nat\} <: \{y:Person\}$.

Third, we need to be able to reorder fields. For example, we might expect that $\{name:String, gpa:Nat, age:Nat\} <: Person$. We haven't quite achieved this yet: using just $S_RcdDepth$ and $S_RcdWidth$ we can only drop fields from the end of a record type. So we need: $\{i1:S1...in:Sn\}$ is a permutation of $\{i1:T1...in:Tn\}$

```
(S_RcdPerm) \{i1:S1...in:Sn\} <: \{i1:T1...in:Tn\}
```

It is worth noting that full-blown language designs may choose not to adopt all of these subtyping rules. For example, in Java:

- A subclass may not change the argument or result types of a method of its superclass (i.e., no depth subtyping or no arrow subtyping, depending how you look at it).
- Each class has just one superclass ("single inheritance" of classes).
- Each class member (field or method) can be assigned a single index, adding new indices "on the right" as more members are added in subclasses (i.e., no permutation for classes).
- A class may implement multiple interfaces so-called "multiple inheritance" of interfaces (i.e., permutation is allowed for interfaces).

Top

Finally, it is natural to give the subtype relation a maximal element – a type that lies above every other type and is inhabited by all (well-typed) values. We do this by adding to the language one new type constant, called *Top*, together with a subtyping rule that places it above every other type in the subtype relation:

(S_Top) S <: Top The Top type is an analog of the Object type in Java and C#.

Summary

In summary, we form the STLC with subtyping by starting with the pure STLC (over some set of base types) and...

• adding a base type *Top*,

 $\bullet\,$ adding the rule of subsumption Gamma |- t : S S <: T

to the typing relation, and

 \bullet defining a subtype relation as follows: S <: U U <: T

$$- \frac{}{} (S_{-} Trans) S <: T$$

$$* \frac{}{} (S_{-} Refl)$$

$$T <: T$$

$$* \frac{}{} (S_{-} Top)$$

$$S <: Top$$

$$S1 <: T1 S2 <: T2$$

$$- \frac{}{} (S_{-} Prod) S1*S2 <: T1*T2$$

$$T1 <: S1 S2 <: T2$$

$$- \frac{}{} (S_{-} Arrow) S1->S2 <: T1->T2$$

$$n > m$$

$$(S_{-} RedWidth) \{i1:T1...in:Tn\} <: \{i1:T1...im:Tm\}$$

$$S1 <: T1 ... Sn <: Tn$$

$$(S_{-} RedDepth) \{i1:S1...in:Sn\} <: \{i1:T1...in:Tn\}$$

$$\{i1:S1...in:Sn\} \text{ is a permutation of } \{i1:T1...in:Tn\}$$

26.2.5 Exercises

Exercise: 1 star, optional (subtype_instances_tf_1) Suppose we have types S, T, U, and V with S <: T and U <: V. Which of the following subtyping assertions are then true? Write true or false after each one. (A, B, and C here are base types.)

- \bullet $T \rightarrow S <: T \rightarrow S$
- \bullet $Top \rightarrow U <: S \rightarrow Top$

- $(C \rightarrow C) \rightarrow (A \times B) <: (C \rightarrow C) \rightarrow (Top \times B)$
- $\bullet \quad T {\rightarrow} \, T {\rightarrow} \, U \, <: \, S {\rightarrow} S {\rightarrow} \, V$
- $(T \rightarrow T)$ -> $U <: (S \rightarrow S)$ ->V
- $((T \rightarrow S)->T)->U<: ((S \rightarrow T)->S)->V$
- \bullet $S \times V <: T \times U$

Exercise: 2 stars (subtype_order) The following types happen to form a linear order with respect to subtyping:

- Top
- $Top \rightarrow Student$
- $Student \rightarrow Person$
- $Student \rightarrow Top$
- \bullet Person \rightarrow Student

Write these types in order from the most specific to the most general. Where does the type $Top \rightarrow Top \rightarrow Student$ fit into this order?

Exercise: 1 star (subtype_instances_tf_2) Which of the following statements are true? Write true or false after each one. forall S T, S <: T -> S->S <: T->T

```
forall S, S <: A->A -> exists T, S = T->T /\ T <: A forall S T1 T1, (S <: T1 -> T2) -> exists S1 S2, S = S1 -> S2 /\ T1 <: S1 /\ S2 <: T2 exists S, S <: S->S exists S, S->S <: S forall S T2 T2, S <: T1*T2 -> exists S1 S2, S = S1*S2 /\ S1 <: T1 /\ S2 <: T2 \Box
```

Exercise: 1 star (subtype_concepts_tf) Which of the following statements are true, and which are false?

- There exists a type that is a supertype of every other type.
- There exists a type that is a subtype of every other type.
- There exists a pair type that is a supertype of every other pair type.
- There exists a pair type that is a subtype of every other pair type.

- There exists an arrow type that is a supertype of every other arrow type.
- There exists an arrow type that is a subtype of every other arrow type.
- There is an infinite descending chain of distinct types in the subtype relation—that is, an infinite sequence of types S0, S1, etc., such that all the Si's are different and each S(i+1) is a subtype of Si.
- There is an infinite ascending chain of distinct types in the subtype relation—that is, an infinite sequence of types S0, S1, etc., such that all the Si's are different and each S(i+1) is a supertype of Si.

Exercise: 2 stars (proper_subtypes) Is the following statement true or false? Briefly explain your answer. forall T, $\tilde{}$ (exists n, T = TBase n) -> exists S, S <: T /\ S <> T || \Box

Exercise: 2 stars (small_large_1)

- What is the *smallest* type T ("smallest" in the subtype relation) that makes the following assertion true? (Assume we have *Unit* among the base types and *unit* as a constant of this type.) empty $|-(\p:T*Top.\p.fst)$ ((\z:A.z), unit): A->A
- What is the *largest* type T that makes the same assertion true?

Exercise: 2 stars (small_large_2)

- What is the *smallest* type T that makes the following assertion true? empty |- (\p:(A->A * B->B). p) ((\z:A.z), (\z:B.z)) : T
- What is the *largest* type T that makes the same assertion true?

Exercise: 2 stars, optional (small_large_3)

- What is the *smallest* type T that makes the following assertion true? a:A |- (\p:(A*T). (p.snd) (p.fst)) (a , \z:A.z) : A
- What is the *largest* type T that makes the same assertion true?

Exercise: 2 stars (small_large_4)

- What is the *smallest* type T that makes the following assertion true? exists S, empty $|-(\p:(A*T). (p.snd) (p.fst)) : <math>S$
- What is the *largest* type T that makes the same assertion true?

Exercise: 2 stars (smallest_1) What is the *smallest* type T that makes the following assertion true? exists S, exists t, empty [-(x:T. x x) t: S]

Exercise: 2 stars (smallest_2) What is the *smallest* type T that makes the following assertion true? empty [-(x:Top. x) ((z:A.z), (z:B.z)) : T]

Exercise: 3 stars, optional (count_supertypes) How many supertypes does the record type $\{x:A, y:C\rightarrow C\}$ have? That is, how many different types T are there such that $\{x:A, y:C\rightarrow C\}$ <: T? (We consider two types to be different if they are written differently, even if each is a subtype of the other. For example, $\{x:A,y:B\}$ and $\{y:B,x:A\}$ are different.)

Exercise: 2 stars (pair_permutation) The subtyping rule for product types S1 <: T1 S2 <: T2

(S_Prod) S1*S2 <: T1*T2 intuitively corresponds to the "depth" subtyping rule for records. Extending the analogy, we might consider adding a "permutation" rule

T1*T2 <: T2*T1 for products. Is this a good idea? Briefly explain why or why not. \Box

26.3 Formal Definitions

Most of the definitions – in particular, the syntax and operational semantics of the language – are identical to what we saw in the last chapter. We just need to extend the typing relation with the subsumption rule and add a new Inductive definition for the subtyping relation. Let's first do the identical bits.

26.3.1 Core Definitions

Syntax

For the sake of more interesting examples below, we'll allow an arbitrary set of additional base types like *String*, *Float*, etc. We won't bother adding any constants belonging to these types or any operators on them, but we could easily do so.

In the rest of the chapter, we formalize just base types, booleans, arrow types, *Unit*, and *Top*, omitting record types and leaving product types as an exercise.

```
Inductive ty : Type :=
    TTop: ty
    TBool: ty
    TBase : id \rightarrow ty
    TArrow : ty \rightarrow ty \rightarrow ty
   TUnit: ty
Tactic Notation "T_cases" tactic(first) ident(c) :=
  first;
    Case\_aux \ c "TTop" | Case\_aux \ c "TBool"
    Case\_aux\ c "TBase" | Case\_aux\ c "TArrow"
    Case_aux c "TUnit" |
Inductive tm : Type :=
   | tvar : id \rightarrow tm
    \mathsf{tapp}: \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}
    tabs : id \rightarrow ty \rightarrow tm \rightarrow tm
    ttrue : tm
    tfalse : tm
   \mathsf{tif}: \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm} \to \mathsf{tm}
   tunit : tm
Tactic Notation "t_cases" tactic(first) ident(c) :=
  first:
   [ Case_aux c "tvar" | Case_aux c "tapp"
    Case\_aux \ c "tabs" | Case\_aux \ c "ttrue"
    Case_aux c "tfalse" | Case_aux c "tif"
    Case\_aux \ c "tunit"
```

Substitution

The definition of substitution remains the same as for the ordinary STLC.

```
Fixpoint subst (x:id) (s:tm) (t:tm) : tm := match \ t with | tvar y \Rightarrow if beq_id x \ y then s else t | tabs y \ T \ t1 \Rightarrow tabs y \ T (if beq_id x \ y then t1 else (subst x \ s \ t1))
```

```
| tapp t1 t2 \Rightarrow
        tapp (subst x \ s \ t1) (subst x \ s \ t2)
  | ttrue \Rightarrow
        ttrue
  | tfalse \Rightarrow
        tfalse
  \mid tif t1 t2 t3 \Rightarrow
        tif (subst x \ s \ t1) (subst x \ s \ t2) (subst x \ s \ t3)
  \mid tunit \Rightarrow
        tunit
  end.
Notation "'[' x ':=' s ']' t" := (subst x \ s \ t) (at level 20).
Reduction
Likewise the definitions of the value property and the step relation.
Inductive value : tm \rightarrow Prop :=
  | v_abs : \forall x T t
        value (tabs x T t)
  t_true:
        value ttrue
  | t_false :
        value tfalse
  | v_unit :
        value tunit
Hint Constructors value.
Reserved Notation "t1'==>'t2" (at level 40).
Inductive step : tm \rightarrow tm \rightarrow Prop :=
  | ST_AppAbs : \forall x T t12 v2,
            value v2 \rightarrow
            (tapp (tabs x \ T \ t12) \ v2) ==> [x := v2] t12
  | ST_App1 : \forall t1 t1' t2,
            t1 ==> t1' \rightarrow
            (tapp t1 t2) ==> (tapp t1' t2)
  \mid ST_App2 : \forall v1 \ t2 \ t2',
            value v1 \rightarrow
            t2 ==> t2' \rightarrow
            (tapp v1 t2) ==> (tapp v1 t2')
  | ST_IfTrue : \forall t1 t2,
        (tif ttrue t1 t2) ==> t1
```

```
 | \, \mathsf{ST\_IfFalse} : \, \forall \, t1 \, t2, \\ (\mathsf{tif} \, \, \mathsf{tfalse} \, t1 \, t2) ==> t2 \\ | \, \mathsf{ST\_If} : \, \forall \, t1 \, t1' \, t2 \, t3, \\ t1 ==> t1' \, \rightarrow \\ (\mathsf{tif} \, t1 \, t2 \, t3) ==> (\mathsf{tif} \, t1' \, t2 \, t3) \\ \mathsf{where} \, "t1 \, '==>' \, t2" := (\mathsf{step} \, t1 \, t2). \\ \mathsf{Tactic} \, \, \mathsf{Notation} \, "\mathsf{step\_cases}" \, tactic(\mathsf{first}) \, ident(c) := \\ \mathsf{first}; \\ [\, \mathit{Case\_aux} \, c \, "\mathsf{ST\_AppAbs}" \, | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_App1}" \\ | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_App2}" \, | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_IfTrue}" \\ | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_IfTrue}" \\ | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_IfTrue}" \\ | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathit{Case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfFalse}" \, | \, \mathsf{case\_aux} \, c \, "\mathsf{ST\_IfT}" \\ | \, \mathsf{case\_aux} \, c \,
```

Hint Constructors step.

26.3.2 Subtyping

Now we come to the most interesting part. We begin by defining the subtyping relation and developing some of its important technical properties.

The definition of subtyping is just what we sketched in the motivating discussion.

Note that we don't need any special rules for base types: they are automatically subtypes of themselves (by $S_{-}Refl$) and Top (by $S_{-}Top$), and that's all we want.

Hint Constructors subtype.

```
Tactic Notation "subtype_cases" tactic(first) ident(c) :=
  first;
  [ Case_aux c "S_Refl" | Case_aux c "S_Trans"
  | Case_aux c "S_Top" | Case_aux c "S_Arrow"
  ].
```

```
Notation x := (Id \ 0).
Notation y := (Id 1).
Notation z := (Id 2).
Notation A := (TBase (Id 6)).
Notation B := (TBase (Id 7)).
Notation C := (TBase (Id 8)).
Notation String := (TBase (Id 9)).
Notation Float := (TBase (Id 10)).
Notation Integer := (TBase (Id 11)).
Exercise: 2 stars, optional (subtyping_judgements) (Do this exercise after you have
added product types to the language, at least up to this point in the file).
   Using the encoding of records into pairs, define pair types representing the record types
Person := { name : String } Student := { name : String ; gpa : Float } Employee := { name
: String; ssn: Integer }
Definition Person: ty :=
admit.
Definition Student: ty :=
admit.
Definition Employee: ty :=
admit.
Example sub_student_person :
  subtype Student Person.
Proof.
   Admitted.
Example sub_employee_person :
  subtype Employee Person.
Proof.
   Admitted.
Example subtyping_example_0 :
  subtype (TArrow C Person)
           (TArrow C TTop).
Proof.
  apply S_Arrow.
    apply S_Refl. auto.
Qed.
```

Module EXAMPLES.

The following facts are mostly easy to prove in Coq. To get full benefit from the exercises, make sure you also understand how to prove them on paper!

```
Exercise: 1 star, optional (subtyping_example_1) Example subtyping_example_1:
  subtype (TArrow TTop Student)
             (TArrow (TArrow C C) Person).
Proof with eauto.
    Admitted.
    Exercise: 1 star, optional (subtyping_example_2) Example subtyping_example_2:
  subtype (TArrow TTop Person)
             (TArrow Person TTop).
Proof with eauto.
    Admitted.
    End EXAMPLES.
26.3.3
            Typing
The only change to the typing relation is the addition of the rule of subsumption, T_{-}Sub.
Definition context := id \rightarrow (option \ ty).
Definition empty: context := (fun \_ \Rightarrow None).
Definition extend (Gamma : context) (x:id) (T : ty) :=
  fun x' \Rightarrow \text{if beq\_id } x \ x' \text{ then Some } T \text{ else } Gamma \ x'.
Inductive \mathsf{has\_type}:\mathsf{context}\to\mathsf{tm}\to\mathsf{ty}\to\mathsf{Prop}:=
  \mid \mathsf{T}_{\mathsf{-}}\mathsf{Var} : \forall \ Gamma \ x \ T,
        Gamma \ x = Some \ T \rightarrow
        has_type Gamma (tvar x) T
  \mid \mathsf{T}_{-}\mathsf{Abs} : \forall \ Gamma \ x \ T11 \ T12 \ t12,
        has_type (extend Gamma \ x \ T11) \ t12 \ T12 \rightarrow
        has_type Gamma (tabs x T11 t12) (TArrow T11 T12)
  \mid \mathsf{T}_{-}\mathsf{App} : \forall T1 \ T2 \ Gamma \ t1 \ t2,
        has_type Gamma\ t1\ (TArrow\ T1\ T2) \rightarrow
        has_type Gamma\ t2\ T1 \rightarrow
        has_type Gamma (tapp t1 t2) T2
  | \mathsf{T}_{\mathsf{-}}\mathsf{True} : \forall Gamma,
         has_type Gamma ttrue TBool
  | T_False : \forall Gamma,
         has_type Gamma tfalse TBool
  \mid T_{-} \text{If} : \forall t1 \ t2 \ t3 \ T \ Gamma,
         has_type Gamma\ t1\ \mathsf{TBool} \to
         has_type Gamma\ t2\ T \rightarrow
         has_type Gamma\ t3\ T \rightarrow
```

```
has_type Gamma (tif t1 t2 t3) T
| T_Unit : ∀ Gamma,
has_type Gamma tunit TUnit

| T_Sub : ∀ Gamma t S T,
has_type Gamma t S →
subtype S T →
has_type Gamma t T.

Hint Constructors has_type.

Tactic Notation "has_type_cases" tactic(first) ident(c) := first;
[ Case_aux c "T_Var" | Case_aux c "T_Abs"
| Case_aux c "T_App" | Case_aux c "T_True"
| Case_aux c "T_False" | Case_aux c "T_If"
| Case_aux c "T_Unit"
| Case_aux c "T_Sub" ].
```

26.3.4 Typing examples

Module EXAMPLES2.

Import Examples.

Do the following exercises after you have added product types to the language. For each informal typing judgement, write it as a formal statement in Coq and prove it.

Exercise:	1 star, optional (typing_example_0) \Box]
Exercise:	2 stars, optional (typing_example_1)	
Exercise:	2 stars, optional (typing_example_2)	
End Examples2.		

26.4 Properties

The fundamental properties of the system that we want to check are the same as always: progress and preservation. Unlike the extension of the STLC with references, we don't need to change the *statements* of these properties to take subtyping into account. However, their proofs do become a little bit more involved.

26.4.1 Inversion Lemmas for Subtyping

Before we look at the properties of the typing relation, we need to record a couple of critical structural properties of the subtype relation:

- Bool is the only subtype of Bool
- every subtype of an arrow type is an arrow type.

These are called *inversion lemmas* because they play the same role in later proofs as the built-in **inversion** tactic: given a hypothesis that there exists a derivation of some subtyping statement S <: T and some constraints on the shape of S and/or T, each one reasons about what this derivation must look like to tell us something further about the shapes of S and T and the existence of subtype relations between their parts.

```
Exercise: 2 stars, optional (sub_inversion_Bool) Lemma sub_inversion_Bool: \forall U,
      subtype U \text{ TBool} \rightarrow
        U = \mathsf{TBool}.
Proof with auto.
  intros U Hs.
  remember TBool as V.
   Admitted.
Exercise: 3 stars, optional (sub_inversion_arrow) Lemma sub_inversion_arrow : \forall U
V1 V2.
      subtype U (TArrow V1 V2) \rightarrow
      \exists U1, \exists U2,
        U = (\mathsf{TArrow}\ U1\ U2) \land (\mathsf{subtype}\ V1\ U1) \land (\mathsf{subtype}\ U2\ V2).
Proof with eauto.
  intros U V1 V2 Hs.
  remember (TArrow V1 V2) as V.
  generalize dependent V2. generalize dependent V1.
   Admitted.
```

26.4.2 Canonical Forms

We'll see first that the proof of the progress theorem doesn't change too much – we just need one small refinement. When we're considering the case where the term in question is an application t1 t2 where both t1 and t2 are values, we need to know that t1 has the form of a lambda-abstraction, so that we can apply the ST_AppAbs reduction rule. In the ordinary STLC, this is obvious: we know that t1 has a function type $T11 \rightarrow T12$, and there is only one rule that can be used to give a function type to a value – rule T_Abs – and the form of the conclusion of this rule forces t1 to be an abstraction.

In the STLC with subtyping, this reasoning doesn't quite work because there's another rule that can be used to show that a value has a function type: subsumption. Fortunately, this possibility doesn't change things much: if the last rule used to show $Gamma \vdash t1$: $T11 \rightarrow T12$ is subsumption, then there is some sub-derivation whose subject is also t1, and we can reason by induction until we finally bottom out at a use of T_Abs .

This bit of reasoning is packaged up in the following lemma, which tells us the possible "canonical forms" (i.e. values) of function type.

```
Exercise: 3 stars, optional (canonical_forms_of_arrow_types) Lemma canonical_forms_of_arrow_ty
: \forall Gamma \ s \ T1 \ T2,
  has_type Gamma\ s\ (TArrow\ T1\ T2) \rightarrow
  value s \rightarrow
  \exists x, \exists S1, \exists s2,
      s = tabs x S1 s2.
Proof with eauto.
   Admitted.
   Similarly, the canonical forms of type Bool are the constants true and false.
Lemma canonical_forms_of_Bool : \forall Gamma \ s,
  has_type Gamma \ s \ \mathsf{TBool} \ 	o
  value s \rightarrow
  (s = \mathsf{ttrue} \lor s = \mathsf{tfalse}).
Proof with eauto.
  intros Gamma s Hty Hv.
  remember TBool as T.

26.4.3 Progress

The proof of progress proceeds like the one for the pure STLC, except that in several places we invoke canonical forms lemmas...

Theorem (Progress): For any term t and type T, if $empty \vdash t$: T then t is a value or t = t for some term t.

Proof: Let t and T be given, with $empty \vdash t$: T. Proceed by induction on the typing derivation.

The cases for T_-Abs , T_-Unit , T_-True and T_-False are immediate because abstractions, unit, true, and false are already values. The T_-Var case is vacuous because variables cannot be typed in the empty context. The remaining cases are more interesting:

- If the last step in the typing derivation uses rule T_-App , then there are terms t1 t2 and types T1 and T2 such that t = t1 t2, T = T2, $empty \vdash t1 : T1 \to T2$, and $empty \vdash t2 : T1$. Moreover, by the induction hypothesis, either t1 is a value or it steps, and either t2 is a value or it steps. There are three possibilities to consider:
 - Suppose t1 ==> t1' for some term t1'. Then t1 t2 ==> t1' t2 by ST_App1 .
 - Suppose t1 is a value and t2 ==> t2' for some term t2'. Then t1 t2 ==> t1 t2' by rule ST_App2 because t1 is a value.
 - Finally, suppose t1 and t2 are both values. By Lemma $canonical_forms_for_arrow_types$, we know that t1 has the form $\xspace x: S1.s2$ for some x, S1, and s2. But then $(\xspace x: S1.s2)$ t2 ==> [x:=t2]s2 by ST_AppAbs , since t2 is a value.
- If the final step of the derivation uses rule $T_{-}If$, then there are terms t1, t2, and t3 such that t = if t1 then t2 else t3, with $empty \vdash t1 : Bool$ and with $empty \vdash t2 : T$ and $empty \vdash t3 : T$. Moreover, by the induction hypothesis, either t1 is a value or it steps.
 - If t1 is a value, then by the canonical forms lemma for booleans, either t1 = true or t1 = false. In either case, t can step, using rule ST_IfTrue or $ST_IfFalse$.
 - If t1 can step, then so can t, by rule $ST_{-}If$.
- If the final step of the derivation is by T_Sub , then there is a type S such that S <: T and $empty \vdash t : S$. The desired result is exactly the induction hypothesis for the typing subderivation.

26.4.4 Inversion Lemmas for Typing

The proof of the preservation theorem also becomes a little more complex with the addition of subtyping. The reason is that, as with the "inversion lemmas for subtyping" above, there are a number of facts about the typing relation that are "obvious from the definition" in the pure STLC (and hence can be obtained directly from the inversion tactic) but that require real proofs in the presence of subtyping because there are multiple ways to derive the same has_type statement.

The following "inversion lemma" tells us that, if we have a derivation of some typing statement $Gamma \vdash \backslash x:S1.t2: T$ whose subject is an abstraction, then there must be some subderivation giving a type to the body t2.

Lemma: If $Gamma \vdash \backslash x:S1.t2: T$, then there is a type S2 such that $Gamma, x:S1 \vdash t2: S2$ and $S1 \rightarrow S2 <: T$.

(Notice that the lemma does not say, "then T itself is an arrow type" – this is tempting, but false!)

Proof: Let Gamma, x, S1, t2 and T be given as described. Proceed by induction on the derivation of $Gamma \vdash \xspace \xspa$

- If the last step of the derivation is a use of T_Abs then there is a type T12 such that $T = S1 \rightarrow T12$ and Gamma, $x:S1 \vdash t2 : T12$. Picking T12 for S2 gives us what we need: $S1 \rightarrow T12 <: S1 \rightarrow T12$ follows from S_Refl .
- If the last step of the derivation is a use of T_-Sub then there is a type S such that S <: T and $Gamma \vdash \x:S1.t2 : S$. The IH for the typing subderivation tell us that

there is some type S2 with $S1 \to S2 <: S$ and $Gamma, x:S1 \vdash t2 : S2$. Picking type S2 gives us what we need, since $S1 \to S2 <: T$ then follows by S_Trans .

26.4.7 Preservation

The proof of preservation now proceeds pretty much as in earlier chapters, using the substitution lemma at the appropriate point and again using inversion lemmas from above to extract structural information from typing assumptions.

Theorem (Preservation): If t, t' are terms and T is a type such that $empty \vdash t : T$ and t ==> t', then $empty \vdash t' : T$.

Proof: Let t and T be given such that $empty \vdash t$: T. We go by induction on the structure of this typing derivation, leaving t' general. The cases T_-Abs , T_-Unit , T_-True , and T_-False cases are vacuous because abstractions and constants don't step. Case T_-Var is vacuous as well, since the context is empty.

• If the final step of the derivation is by T_-App , then there are terms t1 t2 and types T1 T2 such that t = t1 t2, T = T2, $empty \vdash t1 : T1 \rightarrow T2$ and $empty \vdash t2 : T1$.

By inspection of the definition of the step relation, there are three ways t1 t2 can step. Cases ST_App1 and ST_App2 follow immediately by the induction hypotheses for the typing subderivations and a use of T_App .

Suppose instead t1 t2 steps by ST_AppAbs . Then $t1 = \xspace x: S.t12$ for some type S and term t12, and t' = [x:=t2]t12.

By lemma abs_arrow , we have T1 <: S and $x:S1 \vdash s2 : T2$. It then follows by the substitution lemma ($substitution_preserves_typing$) that $empty \vdash [x:=t2] \ t12 : T2$ as desired.

- If the final step of the derivation uses rule $T_{-}If$, then there are terms t1, t2, and t3 such that t = if t1 then t2 else t3, with $empty \vdash t1 : Bool$ and with $empty \vdash t2 : T$ and $empty \vdash t3 : T$. Moreover, by the induction hypothesis, if t1 steps

to t1' then $empty \vdash t1$ ': Bool. There are three cases to consider, depending on which rule was used to show t ==> t'.

- * If t ==> t' by rule $ST_{-}If$, then t' = if t1' then t2 else t3 with t1 ==> t1'. By the induction hypothesis, $empty \vdash t1' : Bool$, and so $empty \vdash t' : T$ by $T_{-}If$.
- * If t ==> t' by rule ST_IfTrue or $ST_IfFalse$, then either t' = t2 or t' = t3, and $empty \vdash t'$: T follows by assumption.
- If the final step of the derivation is by T_-Sub , then there is a type S such that S <: T and $empty \vdash t : S$. The result is immediate by the induction hypothesis for the typing subderivation and an application of T_-Sub . \square

26.4.8 Records, via Products and Top

This formalization of the STLC with subtyping has omitted record types, for brevity. If we want to deal with them more seriously, we have two choices.

First, we can treat them as part of the core language, writing down proper syntax, typing, and subtyping rules for them. Chapter RecordSub shows how this extension works.

On the other hand, if we are treating them as a derived form that is desugared in the parser, then we shouldn't need any new rules: we should just check that the existing rules for subtyping product and *Unit* types give rise to reasonable rules for record subtyping via this encoding. To do this, we just need to make one small change to the encoding described earlier: instead of using *Unit* as the base case in the encoding of tuples and the "don't care" placeholder in the encoding of records, we use *Top*. So:

```
{a:Nat, b:Nat} ---> {Nat,Nat} i.e. (Nat,(Nat,Top)) {c:Nat, a:Nat} ---> {Nat,Top,Nat} i.e. (Nat,(Top,(Nat,Top)))
```

The encoding of record values doesn't change at all. It is easy (and instructive) to check that the subtyping rules above are validated by the encoding. For the rest of this chapter, we'll follow this encoding-based approach.

26.4.9 Exercises

Exercise: 2 stars (variations) Each part of this problem suggests a different way of changing the definition of the STLC with Unit and subtyping. (These changes are not cumulative: each part starts from the original language.) In each part, list which properties (Progress, Preservation, both, or neither) become false. If a property becomes false, give a counterexample.

 \bullet Suppose we add the following typing rule: Gamma |- t : S1->S2 S1 <: T1 T1 <: S1 S2 <: T2

• Suppose we add the following reduction rule:

$$- \qquad - (ST_Funny21)$$
unit ==> (\x:Top. x)

• Suppose we add the following subtyping rule:

$$Unit <: Top->Top$$

• Suppose we add the following subtyping rule:

Top->Top <: Unit

• Suppose we add the following evaluation rule:

$$- \frac{\text{ST_Funny5}}{\text{(unit t)}} = > \text{(t unit)}$$

• Suppose we add the same evaluation rule and a new typing rule:

26.5 Exercise: Adding Products

Exercise: 4 stars, optional (products) Adding pairs, projections, and product types to the system we have defined is a relatively straightforward matter. Carry out this extension:

- Add constructors for pairs, first and second projections, and product types to the definitions of ty and tm. (Don't forget to add corresponding cases to T_cases and t_cases .)
- Extend the well-formedness relation in the obvious way.
- Extend the operational semantics with the same reduction rules as in the last chapter.
- \bullet Extend the subtyping relation with this rule: S1 <: T1 S2 <: T2

$$-$$
 ———— (Sub_Prod) S1 * S2 $<:$ T1 * T2

- Extend the typing relation with the same rules for pairs and projections as in the last chapter.
- Extend the proofs of progress, preservation, and all their supporting lemmas to deal with the new constructs. (You'll also need to add some completely new lemmas.)

27.3 Subtyping

Now we come to the interesting part. We begin by defining the subtyping relation and developing some of its important technical properties.

27.3.1 Definition

The definition of subtyping is essentially just what we sketched in the motivating discussion, but we need to add well-formedness side conditions to some of the rules.

```
\texttt{Inductive } \textbf{subtype}: \ \textbf{ty} \rightarrow \textbf{ty} \rightarrow \texttt{Prop}:=
```

```
\begin{array}{l} | \ \mathsf{S\_Refl} : \ \forall \ T, \\ \mathbf{well\_formed\_ty} \ T \rightarrow \\ \mathbf{subtype} \ T \ T \\ | \ \mathsf{S\_Trans} : \ \forall \ S \ U \ T, \\ \mathbf{subtype} \ S \ U \rightarrow \\ \mathbf{subtype} \ U \ T \rightarrow \\ \mathbf{subtype} \ S \ T \end{array}
```

```
\mid \mathsf{S}_{\mathsf{-}}\mathsf{Top} : \forall S,
              well_formed_ty S \rightarrow
              subtype S TTop
       \mid S_A = S_1 = S_2 = S_2 = S_1 = S_2 = S_2 = S_2 = S_1 = S_2 = S_
              subtype T1 S1 \rightarrow
              subtype S2 T2 \rightarrow
              subtype (TArrow S1 S2) (TArrow T1 T2)
       | S_RcdWidth : \forall i T1 T2,
              well_formed_ty (TRCons i \ T1 \ T2) \rightarrow
              subtype (TRCons i T1 T2) TRNil
       | S_RcdDepth : \forall i S1 T1 Sr2 Tr2,
              subtype S1 T1 \rightarrow
              subtype Sr2 Tr2 \rightarrow
              record_ty Sr2 \rightarrow
              record_ty Tr2 \rightarrow
              subtype (TRCons i S1 Sr2) (TRCons i T1 Tr2)
       | S_RcdPerm : \forall i1 i2 T1 T2 Tr3,
              well_formed_ty (TRCons i1\ T1\ (TRCons\ i2\ T2\ Tr3)) \rightarrow
               i1 \neq i2 \rightarrow
              subtype (TRCons i1 T1 (TRCons i2 T2 Tr3))
                                            (TRCons i2 T2 (TRCons i1 T1 Tr3)).
Hint Constructors subtype.

Informal proof of progress:

Theorem : For any term t and type T, if $empty \vdash t$: T then t is a value or t ==> t' for some term t'.

Proof: Let t and T be given such that $empty \vdash t$: T. We go by induction on the typing derivation. Cases T_-Abs and T_-RNil are immediate because abstractions and $\{\}$ are always values. Case T_-Var is vacuous because variables cannot be typed in the empty context.

• If the last step in the typing derivation is by T_-App , then there are terms t1 t2 and types T1 T2 such that t = t1 t2, T = T2, $empty \vdash t1 : T1 \rightarrow T2$ and $empty \vdash t2 : T1$.

The induction hypotheses for these typing derivations yield that t1 is a value or steps, and that t2 is a value or steps. We consider each case:

- Suppose t1 ==> t1' for some term t1'. Then t1 t2 ==> t1' t2 by ST_App1 .
- Otherwise t1 is a value.
 - * Suppose t2 ==> t2' for some term t2'. Then t1 t2 ==> t1 t2' by rule ST_App2 because t1 is a value.
 - * Otherwise, t2 is a value. By lemma $canonical_forms_for_arrow_types$, $t1 = \x:S1.s2$ for some x, S1, and s2. And $(\x:S1.s2)$ t2 ==> [x:=t2]s2 by ST_AppAbs , since t2 is a value.
- If the last step of the derivation is by T-Proj, then there is a term tr, type Tr and label i such that t = tr.i, $empty \vdash tr : Tr$, and $Tlookup \ i \ Tr = Some \ T$.

The IH for the typing subderivation gives us that either tr is a value or it steps. If tr = tr for some term tr, then $tr \cdot i = tr$ by rule ST_Proj1 .

Otherwise, tr is a value. In this case, lemma $lookup_field_in_value$ yields that there is a term ti such that tlookup i tr = Some ti. It follows that tr.i ==> ti by rule $ST_ProjRed$.

- If the final step of the derivation is by T_Sub , then there is a type S such that S <: T and $empty \vdash t : S$. The desired result is exactly the induction hypothesis for the typing subderivation.
- If the final step of the derivation is by $T_{-}RCons$, then there exist some terms t1 tr, types T1 Tr and a label t such that $t = \{i=t1, tr\}$, $T = \{i:T1, Tr\}$, $record_{-}tm$ tr, $record_{-}tm$ Tr, $empty \vdash t1 : T1$ and $empty \vdash tr : Tr$.

The induction hypotheses for these typing derivations yield that t1 is a value or steps, and that tr is a value or steps. We consider each case:

- Suppose t1 ==> t1' for some term t1'. Then $\{i=t1, tr\} ==> \{i=t1', tr\}$ by rule ST_Rcd_Head .
- Otherwise t1 is a value.
 - * Suppose tr ==> tr' for some term tr'. Then $\{i=t1, tr\} ==> \{i=t1, tr'\}$ by rule ST_Rcd_Tail , since t1 is a value.
 - * Otherwise, tr is also a value. So, $\{i=t1, tr\}$ is a value by v_rcons .

   Informal proof of preservation:
   Theorem: If t, t' are terms and T is a type such that empty \vdash t : T and t ==> t', then
empty \vdash t' : T.
```

Proof: Let t and T be given such that $empty \vdash t : T$. We go by induction on the structure of this typing derivation, leaving t' general. Cases T_-Abs and T_-RNil are vacuous because abstractions and $\{\}$ don't step. Case T_-Var is vacuous as well, since the context is empty.

• If the final step of the derivation is by T_-App , then there are terms t1 t2 and types T1 T2 such that t = t1 t2, T = T2, $empty \vdash t1 : T1 \rightarrow T2$ and $empty \vdash t2 : T1$.

By inspection of the definition of the step relation, there are three ways t1 t2 can step. Cases ST_App1 and ST_App2 follow immediately by the induction hypotheses for the typing subderivations and a use of T_App .

Suppose instead t1 t2 steps by ST_AppAbs . Then $t1 = \xspace x: S.t12$ for some type S and term t12, and t' = [x:=t2]t12.

By Lemma abs_arrow , we have T1 <: S and $x:S1 \vdash s2 : T2$. It then follows by lemma $substitution_preserves_typing$ that $empty \vdash [x:=t2]$ t12 : T2 as desired.

- If the final step of the derivation is by T_-Proj , then there is a term tr, type Tr and label i such that t = tr.i, $empty \vdash tr : Tr$, and $Tlookup \ i \ Tr = Some \ T$.
 - The IH for the typing derivation gives us that, for any term tr', if tr ==> tr' then $empty \vdash tr'$ Tr. Inspection of the definition of the step relation reveals that there are two ways a projection can step. Case ST_-Proj1 follows immediately by the IH.
 - Instead suppose tr.i steps by $ST_ProjRcd$. Then tr is a value and there is some term vi such that tlookup i tr = Some vi and t' = vi. But by lemma $lookup_field_in_value$, $empty \vdash vi : Ti$ as desired.
- If the final step of the derivation is by T_-Sub , then there is a type S such that S <: T and $empty \vdash t : S$. The result is immediate by the induction hypothesis for the typing subderivation and an application of T_-Sub .
- If the final step of the derivation is by $T_{-}RCons$, then there exist some terms t1 tr, types T1 Tr and a label t such that $t = \{i=t1, tr\}$, $T = \{i:T1, Tr\}$, $record_{-}tm$ tr, $record_{-}tm$ Tr, $empty \vdash t1 : T1$ and $empty \vdash tr : Tr$.

By the definition of the step relation, t must have stepped by ST_Rcd_Head or ST_Rcd_Tail . In the first case, the result follows by the IH for t1's typing derivation and T_RCons . In the second case, the result follows by the IH for tr's typing derivation, T_RCons , and a use of the $step_preserves_record_tm$ lemma.

27.4.3 Exercises on Typing

Exercise: 2 stars, optional (variations) Each part of this problem suggests a different way of changing the definition of the STLC with records and subtyping. (These changes are not cumulative: each part starts from the original language.) In each part, list which properties (Progress, Preservation, both, or neither) become false. If a property becomes false, give a counterexample.

• Suppose we add the following typing rule: Gamma |- t : S1->S2 S1 <: T1 T1 <: S1 S2 <: T2 • Suppose we add the following reduction rule: - (ST_Funny21) $\{\} ==> (\x:Top. x)$ • Suppose we add the following subtyping rule: - (S_Funny3) {} <: Top->Top • Suppose we add the following subtyping rule: - -----(S_Funny4) $Top->Top <: \{\}$ • Suppose we add the following evaluation rule: - (ST_Funny5) $(\{\}\ t) ==> (t\ \{\})$ • Suppose we add the same evaluation rule *and* a new typing rule: - -----(ST_Funny5) $(\{\}\ t) ==> (t\ \{\})$ - (T_Funny6) empty \mid - $\{\}$: Top->Top • Suppose we *change* the arrow subtyping rule to: S1 <: T1 S2 <: T2

Chapter 28

Library Norm

28.1 Norm: Normalization of STLC

Require Import Stlc.

(This chapter is optional.)

In this chapter, we consider another fundamental theoretical property of the simply typed lambda-calculus: the fact that the evaluation of a well-typed program is guaranteed to halt in a finite number of steps—i.e., every well-typed term is *normalizable*.

Unlike the type-safety properties we have considered so far, the normalization property does not extend to full-blown programming languages, because these languages nearly always extend the simply typed lambda-calculus with constructs, such as general recursion (as we discussed in the MoreStlc chapter) or recursive types, that can be used to write non-terminating programs. However, the issue of normalization reappears at the level of types when we consider the metatheory of polymorphic versions of the lambda calculus such as F_omega: in this system, the language of types effectively contains a copy of the simply typed lambda-calculus, and the termination of the typechecking algorithm will hinge on the fact that a "normalization" operation on type expressions is guaranteed to terminate.

Another reason for studying normalization proofs is that they are some of the most beautiful—and mind-blowing—mathematics to be found in the type theory literature, often (as here) involving the fundamental proof technique of *logical relations*.

The calculus we shall consider here is the simply typed lambda-calculus over a single base type bool and with pairs. We'll give full details of the development for the basic lambda-calculus terms treating bool as an uninterpreted base type, and leave the extension to the boolean operators and pairs to the reader. Even for the base calculus, normalization is not entirely trivial to prove, since each reduction of a term can duplicate redexes in subterms.

Exercise: 1 star Where do we fail if we attempt to prove normalization by a straightforward induction on the size of a well-typed term?

28.2 Language

We begin by repeating the relevant language definition, which is similar to those in the MoreStlc chapter, and supporting results including type preservation and step determinism. (We won't need progress.) You may just wish to skip down to the Normalization section...

28.3 Normalization

Now for the actual normalization proof.

Our goal is to prove that every well-typed term evaluates to a normal form. In fact, it turns out to be convenient to prove something slightly stronger, namely that every well-typed term evaluates to a value. This follows from the weaker property anyway via the Progress lemma (why?) but otherwise we don't need Progress, and we didn't bother re-proving it above.

```
Here's the key definition:
```

```
Definition halts (t:tm): Prop := \exists t', t ==>* t' \land value t'.
    A trivial fact:
Lemma value_halts : \forall v, value v \rightarrow halts v.
Proof.
```

```
intros v H. unfold halts.
∃ v. split.
apply multi_refl.
assumption.
Qed.
```

The key issue in the normalization proof (as in many proofs by induction) is finding a strong enough induction hypothesis. To this end, we begin by defining, for each type T, a set $R_{-}T$ of closed terms of type T. We will specify these sets using a relation R and write R T t when t is in $R_{-}T$. (The sets $R_{-}T$ are sometimes called saturated sets or reducibility candidates.)

Here is the definition of R for the base language:

- R bool t iff t is a closed term of type bool and t halts in a value
- $R(T1 \to T2)$ t iff t is a closed term of type $T1 \to T2$ and t halts in a value and for any term s such that R(T1) s, we have R(T2) (t s).

This definition gives us the strengthened induction hypothesis that we need. Our primary goal is to show that all *programs*—i.e., all closed terms of base type—halt. But closed terms of base type can contain subterms of functional type, so we need to know something about these as well. Moreover, it is not enough to know that these subterms halt, because the application of a normalized function to a normalized argument involves a substitution, which may enable more evaluation steps. So we need a stronger condition for terms of functional type: not only should they halt themselves, but, when applied to halting arguments, they should yield halting results.

The form of R is characteristic of the *logical relations* proof technique. (Since we are just dealing with unary relations here, we could perhaps more properly say *logical predicates*.) If we want to prove some property P of all closed terms of type A, we proceed by proving, by induction on types, that all terms of type A possess property P, all terms of type $A \rightarrow A$ preserve property P, all terms of type $(A \rightarrow A) - > (A \rightarrow A)$ preserve the property of preserving property P, and so on. We do this by defining a family of predicates, indexed by types. For the base type A, the predicate is just P. For functional types, it says that the function should map values satisfying the predicate at the input type to values satisfying the predicate at the output type.

When we come to formalize the definition of R in Coq, we hit a problem. The most obvious formulation would be as a parameterized Inductive proposition like this:

Inductive R: ty -> tm -> Prop:= | R_bool: forall b t, has_type empty t TBool -> halts t -> R TBool t | R_arrow: forall T1 T2 t, has_type empty t (TArrow T1 T2) -> halts t -> (forall s, R T1 s -> R T2 (tapp t s)) -> R (TArrow T1 T2) t.

Unfortunately, Coq rejects this definition because it violates the *strict positivity require*ment for inductive definitions, which says that the type being defined must not occur to the left of an arrow in the type of a constructor argument. Here, it is the third argument to R_arrow , namely $(\forall s, R \ T1 \ s \rightarrow R \ TS \ (tapp \ t \ s))$, and specifically the $R \ T1 \ s$ part, that violates this rule. (The outermost arrows separating the constructor arguments don't count when applying this rule; otherwise we could never have genuinely inductive predicates at all!) The reason for the rule is that types defined with non-positive recursion can be used to build non-terminating functions, which as we know would be a disaster for Coq's logical soundness. Even though the relation we want in this case might be perfectly innocent, Coq still rejects it because it fails the positivity test.

Fortunately, it turns out that we can define R using a Fixpoint:

```
Fixpoint R (T:\mathbf{ty}) (t:\mathbf{tm}) {struct T} : Prop := \mathbf{has\_type} empty t T \land halts t \land (match T with | TBool \Rightarrow True | TArrow T1 T2 \Rightarrow (\forall s, R T1 s \rightarrow R T2 (tapp t s)) | TProd T1 T2 \Rightarrow False end).
```

As immediate consequences of this definition, we have that every element of every set $R_{-}T$ halts in a value and is closed with type t:

```
Lemma R_halts: \forall { T} { t}, R T t \rightarrow halts t. Proof. intros. destruct T; unfold R in H; inversion H; inversion H1; assumption. Qed.
```

```
Lemma R_typable_empty : \forall { T} {t}, R T t \rightarrow has_type empty t T. Proof.
```

intros. destruct T; unfold R in H; inversion H; inversion H1; assumption. Qed.

Now we proceed to show the main result, which is that every well-typed term of type T is an element of $R_{-}T$. Together with $R_{-}halts$, that will show that every well-typed term halts in a value.

28.3.1 Membership in $R_{-}T$ is invariant under evaluation

We start with a preliminary lemma that shows a kind of strong preservation property, namely that membership in $R_{-}T$ is *invariant* under evaluation. We will need this property in both directions, i.e. both to show that a term in $R_{-}T$ stays in $R_{-}T$ when it takes a forward step, and to show that any term that ends up in $R_{-}T$ after a step must have been in $R_{-}T$ to begin with.

First of all, an easy preliminary lemma. Note that in the forward direction the proof depends on the fact that our language is determinstic. This lemma might still be true for non-deterministic languages, but the proof would be harder!

```
Lemma step_preserves_halting : \forall t \ t', (t ==> t') \rightarrow (\text{halts } t \leftrightarrow \text{halts } t'). Proof.
```

```
intros t t' ST. unfold halts. split. Case "->". intros [t''] [STM] V]]. inversion STM; subst. apply ex_falso_quodlibet. apply value__normal in V. unfold normal_form in V. apply V. \exists t'. auto. rewrite (step\_deterministic\_\_\_ST] H). \exists t''. split; assumption. Case "<-". intros [t'0] [STM] V]]. \exists t'0. split; eauto. Qed.
```

Now the main lemma, which comes in two parts, one for each direction. Each proceeds by induction on the structure of the type T. In fact, this is where we make fundamental use of the finiteness of types.

One requirement for staying in $R_{-}T$ is to stay in type T. In the forward direction, we get this from ordinary type Preservation.

```
Lemma step_preserves_R : \forall T \ t \ t', (t ==> t') \rightarrow R \ T \ t \rightarrow R \ T \ t'.
Proof.
 induction T; intros t t' E Rt; unfold R; fold R; unfold R in Rt; fold R in Rt;
                  destruct Rt as [typable\_empty\_t [halts\_t RRt]].
  split. eapply preservation; eauto.
  split. apply (step_preserves_halting _ _ E); eauto.
  auto.
  split. eapply preservation; eauto.
  split. apply (step_preserves_halting _ _ E); eauto.
  intros.
  eapply IHT2.
  apply ST_App1. apply E.
  apply RRt; auto.
    Admitted.
   The generalization to multiple steps is trivial:
Lemma multistep_preserves_R : \forall T \ t \ t',
  (t ==> * t') \rightarrow R T t \rightarrow R T t'.
Proof.
  intros T t t' STM; induction STM; intros.
  assumption.
```

In the reverse direction, we must add the fact that t has type T before stepping as an additional hypothesis.

apply IHSTM. eapply $step_preserves_R$. apply H. assumption.

Qed.

```
Lemma step_preserves_R': \forall \ T \ t \ t', has_type empty t \ T \to (t ==> t') \to R \ T \ t' \to R \ T \ t. Proof.

Admitted.

Lemma multistep_preserves_R': \forall \ T \ t \ t', has_type empty t \ T \to (t ==>* t') \to R \ T \ t' \to R \ T \ t. Proof.

intros T \ t \ t' \ HT \ STM.
induction STM; intros.
assumption.
eapply step\_preserves\_R'. assumption. apply H. apply IHSTM. eapply preservation; eauto. auto.

Qed.
```

28.3.2 Closed instances of terms of type T belong to $R_{-}T$

Now we proceed to show that every term of type T belongs to R_-T . Here, the induction will be on typing derivations (it would be surprising to see a proof about well-typed terms that did not somewhere involve induction on typing derivations!). The only technical difficulty here is in dealing with the abstraction case. Since we are arguing by induction, the demonstration that a term $tabs\ x\ T1\ t2$ belongs to $R_-(T1\to T2)$ should involve applying the induction hypothesis to show that t2 belongs to $R_-(T2)$. But $R_-(T2)$ is defined to be a set of closed terms, while t2 may contain x free, so this does not make sense.

This problem is resolved by using a standard trick to suitably generalize the induction hypothesis: instead of proving a statement involving a closed term, we generalize it to cover all closed instances of an open term t. Informally, the statement of the lemma will look like this:

If $x1:T1,...xn:Tn \vdash t: T \text{ and } v1,...,vn$ are values such that R T1 v1, R T2 v2, ..., R Tn vn, then R T ([x1:=v1][x2:=v2]...[xn:=vn]t).

The proof will proceed by induction on the typing derivation $x1:T1,...xn:Tn \vdash t:T$; the most interesting case will be the one for abstraction.

Multisubstitutions, multi-extensions, and instantiations

However, before we can proceed to formalize the statement and proof of the lemma, we'll need to build some (rather tedious) machinery to deal with the fact that we are performing multiple substitutions on term t and multiple extensions of the typing context. In particular, we must be precise about the order in which the substitutions occur and how they act on each other. Often these details are simply elided in informal paper proofs, but of course Coq won't let us do that. Since here we are substituting closed terms, we don't need to worry about how one substitution might affect the term put in place by another. But we still do need to worry about the order of substitutions, because it is quite possible for the same identifier to appear multiple times among the x1,...xn with different associated vi and vi.

To make everything precise, we will assume that environments are extended from left to right, and multiple substitutions are performed from right to left. To see that this is consistent, suppose we have an environment written as ..., y:bool,...,y:nat,... and a corresponding term substitution written as ...[$y:=(tbool\ true)$]...[$y:=(tnat\ 3)$]...t. Since environments are extended from left to right, the binding y:nat hides the binding y:bool; since substitutions are performed right to left, we do the substitution $y:=(tnat\ 3)$ first, so that the substitution $y:=(tbool\ true)$ has no effect. Substitution thus correctly preserves the type of the term.

With these points in mind, the following definitions should make sense.

A multisubstitution is the result of applying a list of substitutions, which we call an environment.

```
Definition env := list (id \times tm). Fixpoint msubst (ss:env) (t:tm) {struct ss} : tm := match ss with | nil \Rightarrow t | ((x,s)::ss') \Rightarrow msubst ss' ([x:=s]t) end
```

We need similar machinery to talk about repeated extension of a typing context using a list of (identifier, type) pairs, which we call a *type assignment*.

```
Definition tass := list (id \times ty).

Fixpoint mextend (Gamma : context) (xts : tass) := match xts with | \ nil \Rightarrow Gamma \ | \ ((x,v)::xts') \Rightarrow \text{ extend (mextend } Gamma \ xts') \ x \ v \ \text{end.}
```

We will need some simple operations that work uniformly on environments and type assigments

```
Fixpoint lookup \{X: \mathsf{Set}\}\ (k: \mathsf{id})\ (l: \mathsf{list}\ (\mathsf{id} \times X))\ \{\mathsf{struct}\ l\}: \mathsf{option}\ X := \mathsf{match}\ l\ \mathsf{with}
|\ \mathsf{nil} \Rightarrow \mathsf{None}\ |\ (j,x) :: l' \Rightarrow \\ \mathsf{if}\ \mathsf{beq\_id}\ j\ k\ \mathsf{then}\ \mathsf{Some}\ x\ \mathsf{else}\ \mathsf{lookup}\ k\ l' \\ \mathsf{end}.
Fixpoint drop \{X: \mathsf{Set}\}\ (n: \mathsf{id})\ (nxs: \mathsf{list}\ (\mathsf{id} \times X))\ \{\mathsf{struct}\ nxs\}: \mathsf{list}\ (\mathsf{id} \times X) := \\ \mathsf{match}\ nxs\ \mathsf{with}
|\ \mathsf{nil} \Rightarrow \mathsf{nil}\ |\ ((n',x)::nxs') \Rightarrow \mathsf{if}\ \mathsf{beq\_id}\ n'\ n\ \mathsf{then}\ \mathsf{drop}\ n\ nxs'\ \mathsf{else}\ (n',x):: (\mathsf{drop}\ n\ nxs') \\ \mathsf{end}.
```

An *instantiation* combines a type assignment and a value environment with the same domains, where corresponding elements are in R

```
Inductive instantiation : tass \rightarrow env \rightarrow Prop :=
```

```
| V_nil : instantiation nil nil | V_cons : \forall x \ T \ v \ c \ e, value v \to \mathsf{R} \ T \ v \to \mathsf{instantiation} \ c \ e \to \mathsf{instantiation} \ ((x, T) :: c) \ ((x, v) :: e).
```

We now proceed to prove various properties of these definitions.

More Substitution Facts

```
First we need some additional lemmas on (ordinary) substitution.
```

```

Chapter 29

Library LibTactics

29.1 LibTactics: A Collection of Handy General-Purpose Tactics

This file contains a set of tactics that extends the set of builtin tactics provided with the standard distribution of Coq. It intends to overcome a number of limitations of the standard set of tactics, and thereby to help user to write shorter and more robust scripts.

Hopefully, Coq tactics will be improved as time goes by, and this file should ultimately be useless. In the meanwhile, serious Coq users will probably find it very useful.

The present file contains the implementation and the detailed documentation of those tactics. The SF reader need not read this file; instead, he/she is encouraged to read the chapter named UseTactics.v, which is gentle introduction to the most useful tactics from the LibTactic library.

The main features offered are:

- More convenient syntax for naming hypotheses, with tactics for introduction and inversion that take as input only the name of hypotheses of type Prop, rather than the name of all variables.
- Tactics providing true support for manipulating N-ary conjunctions, disjunctions and existentials, hidding the fact that the underlying implementation is based on binary predicates.
- Convenient support for automation: tactic followed with the symbol "~" or "*" will call automation on the generated subgoals. Symbol "~" stands for auto and "*" for intuition eauto. These bindings can be customized.
- Forward-chaining tactics are provided to instantiate lemmas either with variable or hypotheses or a mix of both.
- A more powerful implementation of apply is provided (it is based on refine and thus behaves better with respect to conversion).

- An improved inversion tactic which substitutes equalities on variables generated by the standard inversion mecanism. Moreover, it supports the elimination of dependently-typed equalities (requires axiom K, which is a weak form of Proof Irrelevance).
- Tactics for saving time when writing proofs, with tactics to asserts hypotheses or subgoals, and improved tactics for clearing, renaming, and sorting hypotheses.

External credits:

- thanks to Xavier Leroy for providing the idea of tactic forward,
- thanks to Georges Gonthier for the implementation trick in rapply,

Set Implicit Arguments.

29.2 Additional notations for Coq

29.2.1 N-ary Existentials

 $\exists T1 \dots TN, P \text{ is a shorthand for } \exists T1, \dots, \exists TN, P. \text{ Note that } Coq.Program.Syntax \text{ already defines exists for arity up to } 4.$

```
Notation "'exists' x1 ',' P" :=
  (\exists x1, P)
  (at level 200, x1 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 ',' P" :=
  (\exists x1, \exists x2, P)
  (at level 200, x1 ident, x2 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 ',' P" :=
  (\exists x1, \exists x2, \exists x3, P)
  (at level 200, x1 ident, x2 ident, x3 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, P)
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, P)
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, \exists x6, P)
```

```
(at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident,
    right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 x7 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, \exists x6,
    \exists x7, P
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident, x7 ident,
    right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 x7 x8 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, \exists x6,
    \exists x7, \exists x8, P
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident, x7 ident, x8 ident,
   right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 x7 x8 x9 ',' P" :=
  (\exists \ x1 , \exists \ x2 , \exists \ x3 , \exists \ x4 , \exists \ x5 , \exists \ x6 ,
    \exists x7, \exists x8, \exists x9, P
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident, x7 ident, x8 ident, x9 ident,
    right associativity): type_scope.
Notation "'exists' x1 x2 x3 x4 x5 x6 x7 x8 x9 x10 ',' P" :=
  (\exists x1, \exists x2, \exists x3, \exists x4, \exists x5, \exists x6,
    \exists x7, \exists x8, \exists x9, \exists x10, P)
  (at level 200, x1 ident, x2 ident, x3 ident, x4 ident, x5 ident,
    x6 ident, x7 ident, x8 ident, x9 ident, x10 ident,
   right associativity): type_scope.
```

29.3 Tools for programming with Ltac

29.3.1 Identity continuation

```
Ltac idcont \ tt := idtac.
```

29.3.2 Untyped arguments for tactics

Any Coq value can be boxed into the type *Boxer*. This is useful to use Coq computations for implementing tactics.

```
Inductive Boxer : Type := | boxer : \forall (A:Type), A \rightarrow Boxer.
```

29.3.3 Optional arguments for tactics

 $ltac_no_arg$ is a constant that can be used to simulate optional arguments in tactic definitions. Use $mytactic\ ltac_no_arg$ on the tactic invokation, and use match $arg\ with\ ltac_no_arg$ \Rightarrow .. or match $type\ of\ arg\ with\ ltac_No_arg$ \Rightarrow .. to test whether an argument was provided.

```
Inductive Itac_No_arg : Set :=
    | Itac_no_arg : Itac_No_arg.
```

29.3.4 Wildcard arguments for tactics

ltac_wild is a constant that can be used to simulate wildcard arguments in tactic definitions. Notation is __.

```
Inductive ltac_Wild : Set :=
    | ltac_wild : ltac_Wild.
Notation "'__'" := ltac_wild : ltac_scope.
```

 $ltac_wilds$ is another constant that is typically used to simulate a sequence of N wildcards, with N chosen appropriately depending on the context. Notation is $___$.

```
Inductive Itac_Wilds : Set :=
    | Itac_wilds : Itac_Wilds.
Notation "'-_-'" := Itac_wilds : ltac_scope.
Open Scope ltac_scope.
```

29.3.5 Position markers

ltac_Mark and *ltac_mark* are dummy definitions used as sentinel by tactics, to mark a certain position in the context or in the goal.

```
Inductive Itac_Mark : Type :=
    | Itac_mark : Itac_Mark.
```

gen_until_mark repeats generalize on hypotheses from the context, starting from the bottom and stopping as soon as reaching an hypothesis of type Mark. If fails if Mark does not appear in the context.

```
Ltac gen\_until\_mark :=
match goal with H: ?T \vdash \_ \Rightarrow
match T with

| Itac_Mark \Rightarrow clear H
| \_ \Rightarrow generalize H; clear H; gen\_until\_mark end end.
```

intro_until_mark repeats intro until reaching an hypothesis of type Mark. It throws away the hypothesis Mark. It fails if Mark does not appear as an hypothesis in the goal.

```
Ltac intro\_until\_mark :=
```

```
match goal with |\vdash (ltac\_Mark \rightarrow \_) \Rightarrow intros \_ |\_ \Rightarrow intro; intro\_until\_mark end.
```

29.3.6 List of arguments for tactics

A datatype of type *list Boxer* is used to manipulate list of Coq values in ltac. Notation is v1 v2 ... vN for building a list containing the values v1 through vN.

```
Require Import List.
Notation "'> '" :=
  (@nil Boxer)
  (at level 0)
  : ltac\_scope.
Notation "'\gg' v1" :=
  ((boxer v1)::nil)
  (at level 0, v1 at level 0)
  : ltac\_scope.
Notation "'> v1 v2" :=

```

```
 v12 \text{ at level } 0) \\ : ltac\_scope. \\ \text{Notation "'>" v1 v2 v3 v4 v5 v6 v7 v8 v9 v10 v11 v12 v13" := } \\ ((\text{boxer } v1) :: (\text{boxer } v2) :: (\text{boxer } v3) :: (\text{boxer } v4) :: (\text{boxer } v5) \\ :: (\text{boxer } v6) :: (\text{boxer } v7) :: (\text{boxer } v8) :: (\text{boxer } v9) :: (\text{boxer } v10) \\ :: (\text{boxer } v11) :: (\text{boxer } v12) :: (\text{boxer } v13) :: \text{nil}) \\ (\text{at level } 0, v1 \text{ at level } 0, v2 \text{ at level } 0, v3 \text{ at level } 0, \\ v4 \text{ at level } 0, v5 \text{ at level } 0, v6 \text{ at level } 0, v7 \text{ at level } 0, \\ v8 \text{ at level } 0, v9 \text{ at level } 0, v10 \text{ at level } 0, v11 \text{ at level } 0, \\ v12 \text{ at level } 0, v13 \text{ at level } 0) \\ : ltac\_scope. \\ \end{aligned}
```

The tactic $list_boxer_of$ inputs a term E and returns a term of type "list boxer", according to the following rules:

- if E is already of type "list Boxer", then it returns E;
- otherwise, it returns the list (boxer E)::nil.

29.3.7 Databases of lemmas

Use the hint facility to implement a database mapping terms to terms. To declare a new database, use a definition: Definition mydatabase := True.

Then, to map mykey to myvalue, write the hint: Hint Extern 1 (Register mydatabase mykey) \Rightarrow Provide myvalue.

Finally, to query the value associated with a key, run the tactic *ltac_database_get my-database mykey*. This will leave at the head of the goal the term *myvalue*. It can then be named and exploited using intro.

```
Definition ltac_database (D:\mathbf{Boxer}) (T:\mathbf{Boxer}) (A:\mathbf{Boxer}) := \mathbf{True}. Notation "'Register' D T" := (ltac_database (boxer D) (boxer T) _) (at level 69, D at level 0, T at level 0).

Lemma ltac_database_provide : \forall (A:\mathbf{Boxer}) (D:\mathbf{Boxer}) (T:\mathbf{Boxer}), ltac_database D T A.

Proof. split. Qed.

Ltac Provide T := apply (@ltac_database_provide (boxer T)).

Ltac ltac\_database\_get D T :=
```

```
let A := fresh "TEMP" in evar (A:Boxer);
let H := fresh "TEMP" in
assert (H : ltac\_database (boxer D) (boxer T) A);
\mid subst A; auto
 subst A; match type of H with ltac_database \_ (boxer ?L) \Rightarrow
              generalize L end; clear H |.
```

On-the-fly removal of hypotheses 29.3.8

In a list of arguments » H1 H2 .. HN passed to a tactic such as lets or applys or forwards or specializes, the term rm, an identity function, can be placed in front of the name of an hypothesis to be deleted.

```
Definition rm (A:Type)(X:A) := X.
   rm_term E removes one hypothesis that admits the same type as E.
Ltac rm_{-}term E :=
  let T := type \ of \ E in
  match goal with H: T \vdash \bot \Rightarrow \text{try clear } H \text{ end.}
   rm_inside E calls rm_term Ei for any subterm of the form rm Ei found in E
Ltac rm\_inside\ E :=
  let go\ E := rm\_inside\ E in
  \mathtt{match}\ E with
   rm ?X \Rightarrow rm\_term X
  |?X1?X2\Rightarrow
     go X1; go X2
  |?X1?X2?X3 \Rightarrow
     go X1; go X2; go X3
  |?X1?X2?X3?X4 \Rightarrow
     go X1; go X2; go X3; go X4
  |?X1?X2?X3?X4?X5 \Rightarrow
     go X1; go X2; go X3; go X4; go X5
  |?X1?X2?X3?X4?X5?X6\Rightarrow
     qo X1; qo X2; qo X3; qo X4; qo X5; qo X6
  |?X1?X2?X3?X4?X5?X6?X7 \Rightarrow
     qo X1; qo X2; qo X3; qo X4; qo X5; qo X6; qo X7
  |?X1?X2?X3?X4?X5?X6?X7?X8 \Rightarrow
     go X1; go X2; go X3; go X4; go X5; go X6; go X7; go X8
  |?X1?X2?X3?X4?X5?X6?X7?X8?X9 \Rightarrow
     go X1; go X2; go X3; go X4; go X5; go X6; go X7; go X8; go X9
  |?X1?X2?X3?X4?X5?X6?X7?X8?X9?X10 \Rightarrow
     go X1; go X2; go X3; go X4; go X5; go X6; go X7; go X8; go X9; go X10
  |  _{-} \Rightarrow idtac
```

end.

For faster performance, one may deactivate rm_inside by replacing the body of this definition with idtac.

```
Ltac fast\_rm\_inside\ E := rm\_inside\ E.
```

29.3.9 Numbers as arguments

When tactic takes a natural number as argument, it may be parsed either as a natural number or as a relative number. In order for tactics to convert their arguments into natural numbers, we provide a conversion tactic.

Require BinPos Coq.ZArith.BinInt.

```
Definition ltac_nat_from_int (x:BinInt.Z): nat:= match \ x \ with
| \ BinInt.Z0 \Rightarrow 0\% nat 
| \ BinInt.Zpos \ p \Rightarrow BinPos.nat\_of\_P \ p
| \ BinInt.Zneg \ p \Rightarrow 0\% nat 
end.

Ltac nat\_from\_number \ N:= match \ type \ of \ N \ with
| \ nat \Rightarrow constr:(N) 
| \ BinInt.Z \Rightarrow let \ N':= constr:(ltac_nat\_from\_int \ N) \ in \ eval \ compute \ in \ N' \ end.
```

 $ltac_pattern\ E$ at K is the same as pattern E at K except that K is a Coq natural rather than a Ltac integer. Syntax $ltac_pattern\ E$ as K in H is also available.

```
Tactic Notation "ltac_pattern" \operatorname{constr}(E) "at" \operatorname{constr}(K) := \operatorname{match} nat\_from\_number K with |1 \Rightarrow \operatorname{pattern} E \text{ at } 1 |2 \Rightarrow \operatorname{pattern} E \text{ at } 2 |3 \Rightarrow \operatorname{pattern} E \text{ at } 3 |4 \Rightarrow \operatorname{pattern} E \text{ at } 4 |5 \Rightarrow \operatorname{pattern} E \text{ at } 5 |6 \Rightarrow \operatorname{pattern} E \text{ at } 6 |7 \Rightarrow \operatorname{pattern} E \text{ at } 7 |8 \Rightarrow \operatorname{pattern} E \text{ at } 8 end. Tactic Notation "ltac_pattern" \operatorname{constr}(E) "at" \operatorname{constr}(K) "in" \operatorname{hyp}(H) := \operatorname{match} nat\_from\_number K with |1 \Rightarrow \operatorname{pattern} E \text{ at } 1 \text{ in } H |2 \Rightarrow \operatorname{pattern} E \text{ at } 2 \text{ in } H
```

```
\mid 3 \Rightarrow \text{pattern } E \text{ at } 3 \text{ in } H
\mid 4 \Rightarrow \text{pattern } E \text{ at } 4 \text{ in } H
\mid 5 \Rightarrow \text{pattern } E \text{ at } 5 \text{ in } H
\mid 6 \Rightarrow \text{pattern } E \text{ at } 6 \text{ in } H
\mid 7 \Rightarrow \text{pattern } E \text{ at } 7 \text{ in } H
\mid 8 \Rightarrow \text{pattern } E \text{ at } 8 \text{ in } H
end.
```

29.3.10 Testing tactics

show tac executes a tactic tac that produces a result, and then display its result.

```
Tactic Notation "show" tactic(tac) := let R := tac in pose R.
```

 $dup\ N$ produces N copies of the current goal. It is useful for building examples on which to illustrate behaviour of tactics. dup is short for $dup\ 2$.

```
Lemma dup_lemma : \forall \ P, \ P \rightarrow P \rightarrow P. Proof. auto. Qed.

Ltac dup\_tactic \ N :=
   match nat\_from\_number \ N with |\ 0 \Rightarrow idtac \ |\ S \ 0 \Rightarrow idtac \ |\ S \ ?N' \Rightarrow apply \ dup\_lemma; [\ |\ dup\_tactic \ N'\ ] end.

Tactic Notation "dup" constr(N) := dup\_tactic \ N.

Tactic Notation "dup" := dup\ 2.
```

29.3.11 Check no evar in goal

```
Ltac check\_noevar\ M:= match M with M\Rightarrow idtac end.

Ltac check\_noevar\_hyp\ H:= let T:=type\ of\ H in match type\ of\ H with T\Rightarrow idtac end.

Ltac check\_noevar\_goal:= match goal with \vdash\ ?G\Rightarrow match G with G\Rightarrow idtac end end.
```

29.3.12 Tagging of hypotheses

 get_last_hyp tt is a function that returns the last hypothesis at the bottom of the context. It is useful to obtain the default name associated with the hypothesis, e.g. intro; let $H := get_last_hyp$ tt in let H' := fresh "P" H in ...

```
Ltac get\_last\_hyp \ tt := match goal with H: \_ \vdash \_ \Rightarrow constr:(H) end.
```

29.3.13 Tagging of hypotheses

ltac_tag_subst is a specific marker for hypotheses which is used to tag hypotheses that are equalities to be substituted.

```
Definition ltac_tag_subst (A:Type) (x:A) := x.

ltac\_to\_generalize is a specific marker for hypotheses to be generalized. 
Definition ltac_to\_generalize (A:Type) (x:A) := x.

Ltac gen\_to\_generalize :=

repeat match goal with

H: ltac_to_generalize \_\vdash \_\Rightarrow generalize H; clear H end.

Ltac mark\_to\_generalize H:=

let T:=type of H in
```

29.3.14 Deconstructing terms

change T with (ltac_to_generalize T) in H.

 $get_head\ E$ is a tactic that returns the head constant of the term E, ie, when applied to a term of the form $P\ x1\ ...\ xN$ it returns P. If E is not an application, it returns E. Warning: the tactic seems to loop in some cases when the goal is a product and one uses the result of this function.

```
|?P \rightarrow constr:(P)
|?P \Rightarrow constr:(P)
end.
```

 $get_fun_arg\ E$ is a tactic that decomposes an application term E, ie, when applied to a term of the form X1 ... XN it returns a pair made of X1 .. X(N-1) and XN.

```
Ltac get\_fun\_arg\ E := match E with |?X1?X2?X3?X4?X5?X6?X7?X \Rightarrow constr:((X1 X2 X3 X4 X5 X6,X)) |?X1?X2?X3?X4?X5?X6?X \Rightarrow constr:((X1 X2 X3 X4 X5,X)) |?X1?X2?X3?X4?X5?X \Rightarrow constr:((X1 X2 X3 X4,X)) |?X1?X2?X3?X4?X \Rightarrow constr:((X1 X2 X3 X4,X)) |?X1?X2?X3?X4?X \Rightarrow constr:((X1 X2 X3,X)) |?X1?X2?X3?X \Rightarrow constr:((X1 X2,X)) |?X1?X2?X \Rightarrow constr:((X1,X)) |?X1?X2?X \Rightarrow constr:((X1,X)) end.
```

29.3.15 Action at occurrence and action not at occurrence

 $ltac_action_at\ K\ of\ E\ do\ Tac$ isolates the K-th occurrence of E in the goal, setting it in the form $P\ E$ for some named pattern P, then calls tactic Tac, and finally unfolds P. Syntax $ltac_action_at\ K\ of\ E\ in\ H\ do\ Tac$ is also available.

```
Tactic Notation "ltac_action_at" constr(K) "of" constr(E) "do" tactic(Tac) := let p := fresh in <math>ltac\_pattern \ E at K; match goal with \vdash ?P \ \_ \Rightarrow set \ (p := P) end; Tac; unfold p; clear p.

Tactic Notation "ltac_action_at" constr(K) "of" constr(E) "in" hyp(H) "do" tactic(Tac) := let p := fresh in <math>ltac\_pattern \ E at K in H; match type \ of \ H with ?P \ \_ \Rightarrow set \ (p := P) in H end; Tac; unfold p in H; clear p.
```

protects E do Tac temporarily assigns a name to the expression E so that the execution of tactic Tac will not modify E. This is useful for instance to restrict the action of simpl.

```
Tactic Notation "protects" constr(E) "do" tactic(Tac) :=
```

```
let x := \text{fresh "TEMP"} in let H := \text{fresh "TEMP"} in set (X := E) in *; assert (H : X = E) by reflexivity; clearbody \ X; \ Tac; subst x.
```

Tactic Notation "protects" constr(E) "do" tactic(Tac) "/" := $protects\ E$ do Tac.

29.3.16 An alias for eq

eq' is an alias for eq to be used for equalities in inductive definitions, so that they don't get mixed with equalities generated by inversion.

```
Definition eq' := @eq.

Hint Unfold eq'.

Notation "\mathbf{x}'=" \mathbf{y}" := (@eq' \mathbf{x} \mathbf{y})

(at level 70, arguments at next level).
```

29.4 Backward and forward chaining

29.4.1 Application

rapply is a tactic similar to eapply except that it is based on the refine tactics, and thus is strictly more powerful (at least in theory:). In short, it is able to perform on-the-fly conversions when required for arguments to match, and it is able to instantiate existentials when required.

```
Tactic Notation "rapply" constr(t) :=
  first
   eexact (@t)
   refine (@t)
   refine (@t_{-})
   refine (@t \_ \_)
   refine (@t \_ \_ \_)
   refine (@t \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_ \_ \_)
   refine (@t -----)
   refine (@t \_ \_ \_ \_ \_ \_ \_ \_)
   refine (@t \_ \_ \_ \_ \_ \_ \_ \_ \_)
```

The tactics $applys_N$ T, where N is a natural number, provides a more efficient way of using applys T. It avoids trying out all possible arities, by specifying explicitly the arity of function T.

```
Tactic Notation "rapply_0" constr(t) :=
```

```
refine (@t).
Tactic Notation "rapply_1" constr(t) :=
  refine (@t_{-}).
Tactic Notation "rapply_2" constr(t) :=
  refine (@t \_ \_).
Tactic Notation "rapply_3" constr(t) :=
  refine (@t \_ \_ \_).
Tactic Notation "rapply_4" constr(t) :=
  refine (@t \_ \_ \_).
Tactic Notation "rapply_5" constr(t) :=
  refine (@t \_ \_ \_ \_).
Tactic Notation "rapply_6" constr(t) :=
  refine (@t \_ \_ \_ \_ \_).
Tactic Notation "rapply_7" constr(t) :=
  refine (@t \_ \_ \_ \_ \_).
Tactic Notation "rapply_8" constr(t) :=
  refine (@t \_ \_ \_ \_ \_ \_).
Tactic Notation "rapply_9" constr(t) :=
  refine (@t \_ \_ \_ \_ \_ \_ \_).
Tactic Notation "rapply_10" constr(t) :=
  refine (@t \_ \_ \_ \_ \_ \_ \_).
   lets\_base\ H\ E adds an hypothesis H:T to the context, where T is the type of term E.
If H is an introduction pattern, it will destruct H according to the pattern.
Ltac lets\_base\ I\ E := generalize\ E; intros I.
   applys_to H E transform the type of hypothesis H by replacing it by the result of the
application of the term E to H. Intuitively, it is equivalent to lets H: (E H).
Tactic Notation "applys_to" hyp(H) constr(E) :=
  let H' := fresh in rename H into H';
  (first [ lets\_base H (E H') ]
           lets\_base\ H\ (E\ \_\ H')
           lets\_base\ H\ (E\_\_H')
           lets\_base\ H\ (E\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_\_H')
           lets\_base\ H\ (E\_\_\_\_\_\_H')
```

constructors calls constructor or econstructor.

 $lets_base\ H\ (E_____H')$

Tactic Notation "constructors" :=

); clear H'.

first [constructor | econstructor]; unfold eq'.

29.4.2 Assertions

false_goal replaces any goal by the goal False. Contrary to the tactic false (below), it does not try to do anything else

```
Tactic Notation "false_goal" := elimtype False.
```

 $false_post$ is the underlying tactic used to prove goals of the form False. In the default implementation, it proves the goal if the context contains False or an hypothesis of the form $C \ x1 \ ... \ xN = D \ y1 \ ... \ yM$, or if the congruence tactic finds a proof of $x \neq x$ for some x.

```
Ltac false_post :=
solve [assumption | discriminate | congruence].
false replaces any goal by the goal False, and calls false_post
Tactic Notation "false" :=
false_goal; try false_post.
```

tryfalse tries to solve a goal by contradiction, and leaves the goal unchanged if it cannot solve it. It is equivalent to try solve $\setminus [false \setminus]$.

```
Tactic Notation "tryfalse" := try solve [ false ].
```

tryfalse by tac / is that same as tryfalse except that it tries to solve the goal using tactic tac if assumption and discriminate do not apply. It is equivalent to try solve \[false; tac \]. Example: tryfalse by congruence/

```
Tactic Notation "tryfalse" "by" tactic(tac) "/" := try solve [ false; instantiate; tac ].
```

false T tries false; apply T, or otherwise adds T as an assumption and calls false.

```
Tactic Notation "false" \operatorname{constr}(T) "by" \operatorname{tactic}(\operatorname{tac}) "/" := \operatorname{false\_goal}; first [ \operatorname{apply}\ T | \operatorname{eapply}\ T | \operatorname{rapply}\ T]; \operatorname{instantiate};\ \operatorname{tac} | let H := \operatorname{fresh}\ \operatorname{in}\ \operatorname{lets\_base}\ H T; \operatorname{first}\ [\operatorname{discriminate}\ H | \operatorname{false}; \operatorname{instantiate};\ \operatorname{tac}\ ]]. Tactic Notation "false" \operatorname{constr}(T) :=
```

 $false_invert$ proves any goal provided there is at least one hypothesis H in the context that can be proved absurd by calling inversion H.

```
Ltac false\_invert\_tactic := match goal with H:\_\vdash \_ \Rightarrow
```

false T by idtac/.

```
solve [inversion H
            clear H; false_invert_tactic
            fail 2 \mid end.
Tactic Notation "false_invert" :=
  false\_invert\_tactic.
   tryfalse_invert tries to prove the goal using false or false_invert, and leaves the goal
unchanged if it does not succeed.
Tactic Notation "tryfalse_invert" :=
  try solve [ false | false_invert ].
   asserts H: T is another syntax for assert (H: T), which also works with introduction
patterns. For instance, one can write: asserts [x P] (\exists n, n = 3), or asserts [H] ([n]
= 0 \lor n = 1).
Tactic Notation "asserts" simple\_intropattern(I) ":" constr(T) :=
  let H := fresh in assert (H : T);
  [ | generalize H; clear H; intros I ].
   asserts H1 .. HN: T is a shorthand for asserts [H1 \mid [H2 \mid [... HN \mid]]]: T].
Tactic Notation "asserts" simple\_intropattern(I1)
 simple\_intropattern(I2) ":" constr(T) :=
  asserts [I1 I2]: T.
Tactic Notation "asserts" simple\_intropattern(I1)

  cuts [I1 [I2 [I3 [I4 [I5 I6]]]]]: T.
```

29.4.3 Instantiation and forward-chaining

The instantiation tactics are used to instantiate a lemma E (whose type is a product) on some arguments. The type of E is made of implications and universal quantifications, e.g. $\forall x, P \ x \rightarrow \forall y \ z, Q \ x \ y \ z \rightarrow R \ z$.

The first possibility is to provide arguments in order: first x, then a proof of P x, then y etc... In this mode, called "Args", all the arguments are to be provided. If a wildcard is provided (written $_{--}$), then an existential variable will be introduced in place of the argument.

It often saves a lot of time to give only the dependent variables, (here x, y and z), and have the hypotheses generated as subgoals. In this "Vars" mode, only variables are to be provided. For instance, lemma E applied to 3 and 4 is a term of type $\forall z$, Q 3 4 $z \rightarrow R$ z, and P 3 is a new subgoal. It is possible to use wildcards to introduce existential variables.

However, there are situations where some of the hypotheses already exists, and it saves time to instantiate the lemma E using the hypotheses. For instance, suppose F is a term of type P 2. Then the application of E to F in this "Hyps" mode is a term of type $\forall y z, Q$ 2 $y z \rightarrow R z$. Each wildcard use will generate an assertion instead, for instance if G has type G 2 3 4, then the application of E to a wildcard and to G in mode-h is a term of type E 4, and E 2 is a new subgoal.

It is very convenient to give some arguments the lemma should be instantiated on, and let the tactic find out automatically where underscores should be insterted. Underscore arguments __ are interpret as follows: an underscore means that we want to skip the argument that has the same type as the next real argument provided (real means not an underscore). If there is no real argument after underscore, then the underscore is used for the first possible argument.

The general syntax is tactic (» E1 .. EN) where tactic is the name of the tactic (possibly with some arguments) and Ei are the arguments. Moreover, some tactics accept the syntax tactic E1 .. EN as short for tactic (» Hnts E1 .. EN) for values of N up to 5.

Finally, if the argument EN given is a triple-underscore $_{--}$, then it is equivalent to providing a list of wildcards, with the appropriate number of wildcards. This means that all the remaining arguments of the lemma will be instantiated.

```
Ltac app\_assert \ t \ P \ cont :=
  let H := fresh "TEMP" in

```

29.4.4 Experimental tactics for application

fapply is a version of apply based on forwards.

```
Tactic Notation "fapply" constr(E) :=  let H := fresh in forwards \ H : E; first [apply H | eapply H | rapply \ H | hnf; apply H | hnf; apply H | applys \ H ].
```

sapply stands for "super apply". It tries apply, eapply, applys and fapply, and also tries to head-normalize the goal first.

```
Tactic Notation "sapply" \operatorname{constr}(H) :=  first [apply H \mid \operatorname{eapply} H \mid \operatorname{rapply} H \mid \operatorname{applys} H \mid \operatorname{hnf}; \operatorname{apply} H \mid \operatorname{hnf}; \operatorname{apply} H \mid \operatorname{hnf}; \operatorname{apply} H \mid \operatorname{hnf}; \operatorname{apply} H \mid .
```

29.4.5 Adding assumptions

lets_simpl H: E is the same as lets H: E excepts that it calls simpl on the hypothesis H.

```
Tactic Notation "lets_simpl" ident(H) ":" constr(E) := lets \ H: E; simpl \ in \ H.
```

 $lets_hnf\ H$: E is the same as $lets\ H$: E excepts that it calls hnf to set the definition in head normal form.

```
Tactic Notation "lets_hnf" ident(H) ":" constr(E) := lets\ H: E; hnf in H.
```

 $lets_simpl$: E is the same as $lets_simpl$ H: E with the name H being choosed automatically.

```
Tactic Notation "lets_simpl" ":" constr(T) := let H := fresh in lets_simpl H: T.
```

lets_hnf: E is the same as lets_hnf H: E with the name H being choosed automatically.

```
Tactic Notation "lets_hnf" ":" constr(T) := let H := fresh in lets_hnf H: T.
```

put X: E is a synonymous for pose (X := E). Other syntaxes are put: E.

```
Tactic Notation "put" ident(X) ":" constr(E) := pose (X := E).

Tactic Notation "put" ":" constr(E) := let X := fresh "X" in pose (X := E).
```

29.4.6 Application of tautologies

logic E, where E is a fact, is equivalent to assert H:E; [tauto | eapply H; clear H]. It is useful for instance to prove a conjunction $[A \wedge B]$ by showing first [A] and then $[A \rightarrow B]$, through the command $[logic (foral A B, A \rightarrow (A \rightarrow B) \rightarrow A \wedge B)]$

```
Ltac logic\_base\ E\ cont:=
```

```
assert (H:E); [ cont\ tt | eapply H; clear H ]. Tactic Notation "logic" constr(E) := logic\_base\ E ltac:(fun \_\Rightarrow tauto).
```

29.4.7 Application modulo equalities

The tactic equates replaces a goal of the form P x y z with a goal of the form P x ?a z and a subgoal ?a = y. The introduction of the evar ?a makes it possible to apply lemmas that would not apply to the original goal, for example a lemma of the form $\forall n$ m, P n n m, because x and y might be equal but not convertible.

Usage is *equates i1* ... *ik*, where the indices are the positions of the arguments to be replaced by evars, counting from the right-hand side. If 0 is given as argument, then the entire goal is replaced by an evar.

```
Section equatesLemma.
```

29.5 Introduction and generalization

29.5.1 Introduction

introv is used to name only non-dependent hypothesis.

- If *introv* is called on a goal of the form $\forall x, H$, it should introduce all the variables quantified with a \forall at the head of the goal, but it does not introduce hypotheses that preced an arrow constructor, like in $P \to Q$.
- If *introv* is called on a goal that is not of the form $\forall x, H \text{ nor } P \to Q$, the tactic unfolds definitions until the goal takes the form $\forall x, H \text{ or } P \to Q$. If unfolding definitions does not produces a goal of this form, then the tactic *introv* does nothing at all.

```
Ltac introv\_rec :=
match goal with
|\vdash ?P \rightarrow ?Q \Rightarrow idtac
|\vdash \forall \_, \_ \Rightarrow intro; introv\_rec
|\vdash \_ \Rightarrow idtac
end.

Ltac introv\_noarg :=

```

 $intros_all$ repeats intro as long as possible. Contrary to intros, it unfolds any definition on the way. Remark that it also unfolds the definition of negation, so applying introz to a goal of the form $\forall x, P \ x \to \neg Q$ will introduce x and $P \ x$ and Q, and will leave False in the goal.

```
Tactic Notation "intros_all" := repeat intro. intros\_hnf \text{ introduces an hypothesis and sets in head normal form} Tactic Notation "intro\_hnf" := intro; match goal with H: \_\vdash \_ \Rightarrow \text{hnf in } H \text{ end.}
```

29.5.2 Generalization

gen X1 .. XN is a shorthand for calling generalize dependent successively on variables XN...X1. Note that the variables are generalized in reverse order, following the convention of the generalize tactic: it means that X1 will be the first quantified variable in the resulting goal.

```
Tactic Notation "gen" ident(X1) :=
  generalize dependent X1.
Tactic Notation "gen" ident(X1) ident(X2) :=
  qen X2; qen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) :=
  gen X3; gen X2; gen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) ident(X4) :=
  gen X4; gen X3; gen X2; gen X1.
Tactic Notation "gen" ident(X1) ident(X2) ident(X3) ident(X4) ident(X5) :=
  gen X5; gen X4; gen X3; gen X2; gen X1.

  generalizes X1 \ X2 \ X3; generalizes X4.
```

29.5.3 Naming

sets X: E is the same as set(X := E) in *, that is, it replaces all occurrences of E by a fresh meta-variable X whose definition is E.

```
Tactic Notation "sets" ident(X) ":" constr(E) := set(X := E) in *.
```

 $def_{-}to_{-}eq \ E \ X \ H$ applies when X := E is a local definition. It adds an assumption H: X = E and then clears the definition of X. $def_{-}to_{-}eq_{-}sym$ is similar except that it generates the equality H: E = X.

```
Ltac def\_to\_eq\ X\ HX\ E:= assert (HX:X=E) by reflexivity; clearbody\ X. Ltac def\_to\_eq\_sym\ X\ HX\ E:= assert (HX:E=X) by reflexivity; clearbody\ X.
```

 $set_eq\ X\ H$: E generates the equality H: X=E, for a fresh name X, and replaces E by X in the current goal. Syntaxes $set_eq\ X$: E and set_eq : E are also available. Similarly, $set_eq\leftarrow X\ H$: E generates the equality H: E=X.

 $sets_eq\ X\ HX\colon E$ does the same but replaces E by X everywhere in the goal. $sets_eq\ X$ $HX\colon E$ in H replaces in H. $set_eq\ X\ HX\colon E$ in \vdash performs no substitution at all.

```
Tactic Notation "set_eq" ident(X) ident(HX) ":" constr(E) := set(X := E); def\_to\_eq \ X \ HX \ E.

Tactic Notation "set_eq" ident(X) ":" constr(E) := let \ HX := fresh "EQ" X in set\_eq \ X \ HX : E.

Tactic Notation "set_eq" ":" constr(E) := let \ X := fresh "X" in set\_eq \ X : E.
```

```

```

```
let X := fresh "X" in <math>set\_eq \leftarrow X : E in \vdash.
```

 $gen_{-}eq~X$: E is a tactic whose purpose is to introduce equalities so as to work around the limitation of the induction tactic which typically loses information. $gen_{-}eq~E$ as X replaces all occurences of term E with a fresh variable X and the equality X = E as extra hypothesis to the current conclusion. In other words a conclusion C will be turned into $(X = E) \rightarrow C$. $gen_{-}eq$: E and $gen_{-}eq$: E as X are also accepted.

```
Tactic Notation "gen_eq" ident(X) ":" constr(E) := let EQ := fresh in sets\_eq X EQ : E ; revert EQ .
Tactic Notation "gen_eq" ":" constr(E) := let X := fresh "X" in gen\_eq X : E .

Tactic Notation "gen_eq" ident(X1) ":" constr(E1) "," ident(X2) ":" constr(E2) := gen\_eq X2 : E2 ; gen\_eq X1 : E1 .
Tactic Notation "gen_eq" ident(X1) ":" constr(E1) "," ident(X2) ":" constr(E2) "," ident(X2) ":" constr(E3) := constr(E3) ":" constr(E3) ":" constr(E3) := co
```

sets_let X finds the first let-expression in the goal and names its body X. sets_eq_let X is similar, except that it generates an explicit equality. Tactics sets_let X in X and sets_eq_let X in X allow specifying a particular hypothesis (by default, the first one that contains a let is considered).

Known limitation: it does not seem possible to support naming of multiple let-in constructs inside a term, from ltac.

```
Ltac sets\_let\_base \ tac :=
   match goal with
   |\vdash \mathtt{context}[\mathtt{let} \ \_ := ?E \ \mathtt{in} \ \_] \Rightarrow tac \ E; \mathtt{cbv} \ \mathtt{zeta}
   |H: \mathtt{context}[\mathtt{let}_{-} := ?E \mathtt{in}_{-}] \vdash_{-} \Rightarrow tac \ E; \mathtt{cbv} \mathtt{zeta} \mathtt{in} \ H
   end.
Ltac sets\_let\_in\_base\ H\ tac :=
  match type of H with context[let \_ := ?E \text{ in } \_] \Rightarrow
      tac E; cbv zeta in H end.
Tactic Notation "sets_let" ident(X) :=
   sets\_let\_base\ ltac:(fun\ E \Rightarrow sets\ X:\ E).
Tactic Notation "sets_let" ident(X) "in" hyp(H) :=
   sets\_let\_in\_base\ H\ ltac:(fun\ E \Rightarrow sets\ X:\ E).
Tactic Notation "sets_eq_let" ident(X) :=
   sets\_let\_base\ ltac:(fun\ E \Rightarrow sets\_eq\ X:\ E).
Tactic Notation "sets_eq_let" ident(X) "in" hyp(H) :=
   sets\_let\_in\_base\ H\ ltac:(fun\ E \Rightarrow sets\_eq\ X:\ E).
```

29.6 Rewriting

29.6.1 Rewriting

repeat rewrite E.

Tactic Notation "rewrite_all" constr(E) :=

 $rewrite_all\ E$ iterates version of rewrite E as long as possible. Warning: this tactic can easily get into an infinite loop. Syntax for rewriting from right to left and/or into an hypothese is similar to the one of rewrite.

```
Tactic Notation "rewrite_all" "<-" constr(E) :=
  repeat rewrite \leftarrow E.
Tactic Notation "rewrite_all" constr(E) "in" ident(H) :=
  repeat rewrite E in H.
Tactic Notation "rewrite_all" "<-" constr(E) "in" ident(H) :=
  repeat rewrite \leftarrow E in H.
Tactic Notation "rewrite_all" constr(E) "in" "*" :=
  repeat rewrite E in *.
Tactic Notation "rewrite_all" "<-" constr(E) "in" "*" :=
  repeat rewrite \leftarrow E in *.
   asserts_rewrite E asserts that an equality E holds (generating a corresponding subgoal)
and rewrite it straight away in the current goal. It avoids giving a name to the equality and
later clearing it. Syntax for rewriting from right to left and/or into an hypothese is similar
to the one of rewrite. Note: the tactic replaces plays a similar role.
Ltac asserts\_rewrite\_tactic\ E\ action :=
  let EQ := fresh in (assert (EQ : E);
  [ idtac | action EQ; clear EQ ]).
Tactic Notation "asserts_rewrite" constr(E) :=
  asserts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite\ EQ).
Tactic Notation "asserts_rewrite" "<-" constr(E) :=
  asserts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite \leftarrow EQ).
Tactic Notation "asserts_rewrite" constr(E) "in" hyp(H) :=
  asserts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite\ EQ\ in\ H).
Tactic Notation "asserts_rewrite" "<-" constr(E) "in" hyp(H) :=
  asserts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite \leftarrow EQ\ in\ H).
   cuts_rewrite E is the same as asserts_rewrite E except that subgoals are permuted.
Ltac cuts\_rewrite\_tactic\ E\ action :=
  let EQ := fresh in (cuts EQ: E;
  [ action EQ; clear EQ | idtac ]).
Tactic Notation "cuts_rewrite" constr(E) :=
  cuts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite\ EQ).
Tactic Notation "cuts_rewrite" "<-" constr(E) :=
```

```
cuts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite \leftarrow EQ).
Tactic Notation "cuts_rewrite" constr(E) "in" hyp(H) :=
  cuts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite\ EQ\ in\ H).
Tactic Notation "cuts_rewrite" "<-" constr(E) "in" hyp(H) :=
  cuts\_rewrite\_tactic\ E\ ltac:(fun\ EQ \Rightarrow rewrite \leftarrow EQ\ in\ H).
    rewrite\_except \ H \ EQ rewrites equality EQ everywhere but in hypothesis H.
Ltac rewrite\_except \ H \ EQ :=
  let K := fresh in let T := type \ of \ H in
  \operatorname{set}(K := T) \operatorname{in} H;
  rewrite EQ in *; unfold K in H; clear K.
    rewrites E at K applies when E is of the form T1 = T2 rewrites the equality E at the
K-th occurrence of T1 in the current goal. Syntaxes rewrites \leftarrow E at K and rewrites E at
K in H are also available.
Tactic Notation "rewrites" constr(E) "at" constr(K) :=
  match type of E with ?T1 = ?T2 \Rightarrow
     ltac\_action\_at \ K \ of \ T1 \ do \ (rewrite \ E) \ end.
Tactic Notation "rewrites" "<-" constr(E) "at" constr(K) :=
  match type of E with ?T1 = ?T2 \Rightarrow
     ltac\_action\_at \ K \ of \ T2 \ do \ (rewrite \leftarrow E) \ end.
Tactic Notation "rewrites" constr(E) "at" constr(K) "in" hyp(H) :=
  match type of E with ?T1 = ?T2 \Rightarrow
     ltac\_action\_at \ K \ of \ T1 \ in \ H \ do \ (rewrite \ E \ in \ H) \ end.
Tactic Notation "rewrites" "<-" constr(E) "at" constr(K) "in" hyp(H) :=
  match type of E with ?T1 = ?T2 \Rightarrow
     ltac\_action\_at \ K \ of \ T2 \ in \ H \ do \ (rewrite \leftarrow E \ in \ H) \ end.
```

29.6.2 Replace

replaces E with F is the same as replace E with F except that the equality E = F is generated as first subgoal. Syntax replaces E with F in H is also available. Note that contrary to replace, replaces does not try to solve the equality by assumption. Note: replaces E with F is similar to asserts_rewrite (E = F).

```
Tactic Notation "replaces" \operatorname{constr}(E) "with" \operatorname{constr}(F) :=  let T := \operatorname{fresh} in assert (T : E = F); [ | \operatorname{replace} E with F; \operatorname{clear} T ]. Tactic Notation "replaces" \operatorname{constr}(E) "with" \operatorname{constr}(F) "in" \operatorname{hyp}(H) :=  let T := \operatorname{fresh} in assert (T : E = F); [ | \operatorname{replace} E with F in H; \operatorname{clear} T ]. \operatorname{replaces} E at K with F replaces the K-th occurence of E with F in the current goal.
```

replaces E at K with F replaces the K-th occurrence of E with F in the current goal Syntax replaces E at K with F in H is also available.

```
Tactic Notation "replaces" constr(E) "at" constr(K) "with" constr(F) := let T := fresh in assert (T: E = F); [ | rewrites T at K; clear T ].
```

```
Tactic Notation "replaces" constr(E) "at" constr(K) "with" constr(F) "in" hyp(H) := let T := fresh in assert (T: E = F); [ | rewrites\ T at K in H; clear\ T ].
```

29.6.3 Renaming

renames X1 to Y1, ..., XN to YN is a shorthand for a sequence of renaming operations rename Xi into Yi.

```
Tactic Notation "renames" ident(X1) "to" ident(Y1) :=
  rename X1 into Y1.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) :=
  renames X1 to Y1; renames X2 to Y2.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) "," ident(X3) "to" ident(Y3) :=
  renames X1 to Y1; renames X2 to Y2, X3 to Y3.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) "," ident(X3) "to" ident(Y3) ","
 ident(X_4) "to" ident(Y_4) :=
  renames X1 to Y1; renames X2 to Y2, X3 to Y3, X4 to Y4.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) "," ident(X3) "to" ident(Y3) ","
 ident(X4) "to" ident(Y4) "," ident(X5) "to" ident(Y5) :=
  renames X1 to Y1; renames X2 to Y2, X3 to Y3, X4 to Y4, X5 to Y5.
Tactic Notation "renames" ident(X1) "to" ident(Y1) ","
 ident(X2) "to" ident(Y2) "," ident(X3) "to" ident(Y3) ","
 ident(X4) "to" ident(Y4) "," ident(X5) "to" ident(Y5) ","
 ident(X6) "to" ident(Y6) :=
  renames X1 to Y1; renames X2 to Y2, X3 to Y3, X4 to Y4, X5 to Y5, X6 to Y6.
```

29.6.4 Unfolding

unfolds unfolds the head definition in the goal, i.e. if the goal has form $P \ x1 \dots xN$ then it calls unfold P. If the goal is an equality, it tries to unfold the head constant on the left-hand side, and otherwise tries on the right-hand side. If the goal is a product, it calls intros first.

```
Ltac apply\_to\_head\_of\ E\ cont:=
let go\ E:=
let P:=get\_head\ E\ in\ cont\ P\ in
match E\ with
|\ \forall\ \_,\_\ \Rightarrow\ intros;\ apply\_to\_head\_of\ E\ cont
|\ ?A=?B\ \Rightarrow\ first\ [\ go\ A\ |\ go\ B\ ]
```

```
|?A \Rightarrow go A
  end.
Ltac unfolds\_base :=
  match goal with \vdash ?G \Rightarrow
   apply\_to\_head\_of \ G \ ltac:(fun \ P \Rightarrow unfold \ P) \ end.
Tactic Notation "unfolds" :=
  unfolds\_base.
   unfolds in H unfolds the head definition of hypothesis H, i.e. if H has type P x1 \dots xN
then it calls unfold P in H.
Ltac unfolds\_in\_base\ H :=
  match type of H with ?G \Rightarrow
   apply\_to\_head\_of \ G \ ltac:(fun \ P \Rightarrow unfold \ P \ in \ H) \ end.
Tactic Notation "unfolds" "in" hyp(H) :=
  unfolds\_in\_base\ H.
   unfolds P1,..,PN is a shortcut for unfold P1,..,PN in *.
Tactic Notation "unfolds" reference(F1) :=
  unfold F1 in *.
Tactic Notation "unfolds" reference(F1) "," reference(F2) :=

29.6.5
          Simplification
simpls is a shortcut for simpl in *.
Tactic Notation "simpls" :=
  simpl in *.
   simple P1,..,PN is a shortcut for simpl P1 in *; ..; simpl PN in *.
Tactic Notation "simpls" reference(F1) :=
  simpl F1 in *.
Tactic Notation "simpls" reference(F1) "," reference(F2) :=
  simpls F1; simpls F2.
Tactic Notation "simpls" reference(F1) "," reference(F2)
 "," reference(F3) :=
  simpls F1; simpls F2; simpls F3.
Tactic Notation "simpls" reference(F1) "," reference(F2)
 "," reference(F3) "," reference(F4) :=
  simpls F1; simpls F2; simpls F3; simpls F4.
   unsimpl E replaces all occurrence of X by E, where X is the result which the tactic simpl
would give when applied to E. It is useful to undo what simpl has simplified too far.
Tactic Notation "unsimpl" constr(E) :=
  let F := (eval simpl in E) in change F with E.
   unsimpl\ E in H is similar to unsimpl\ E but it applies inside a particular hypothesis H.
Tactic Notation "unsimpl" constr(E) "in" hyp(H) :=
  let F := (eval simpl in E) in change F with E in H.
   unsimpl\ E in * applies unsimpl\ E everywhere possible. unsimpls\ E is a synonymous.
Tactic Notation "unsimpl" constr(E) "in" "*" :=
  let F := (\text{eval simpl in } E) in change F with E in *.
Tactic Notation "unsimpls" constr(E) :=
```

```
unsimpl E in *.
```

 $nosimpl\ t$ protects the Coq term t against some forms of simplification. See Gonthier's work for details on this trick.

```
Notation "'nosimpl' t" := (match tt with tt \Rightarrow t end) (at level 10).
```

29.6.6 Evaluation

```
Tactic Notation "hnfs" := hnf in *.
```

29.6.7 Substitution

substs does the same as subst, except that it does not fail when there are circular equalities in the context.

```
Tactic Notation "substs" := repeat (match goal with H: ?x = ?y \vdash \_ \Rightarrow first [ subst x | subst y ] end).
```

Implementation of *substs below*, which allows to call **subst** on all the hypotheses that lie beyond a given position in the proof context.

```
Ltac substs\_below\ limit :=
match goal with H\colon ?T \vdash \_\Rightarrow
match T with
|\ limit \Rightarrow \mathtt{idtac}|
|\ ?x = ?y \Rightarrow
first\ [\ \mathtt{subst}\ x;\ substs\_below\ limit
|\ \mathtt{subst}\ y;\ substs\_below\ limit
|\ generalizes\ H;\ substs\_below\ limit;\ \mathtt{intro}\ ]
end end.
```

substs below body E applies subst on all equalities that appear in the context below the first hypothesis whose body is E. If there is no such hypothesis in the context, it is equivalent to subst. For instance, if E is an hypothesis, then substs below E will substitute equalities below hypothesis E.

```
Tactic Notation "substs" "below" "body" constr(M) := substs\_below M.
```

substs below H applies subst on all equalities that appear in the context below the hypothesis named H. Note that the current implementation is technically incorrect since it will confuse different hypotheses with the same body.

```
Tactic Notation "substs" "below" hyp(H) := match type \ of \ H with ?M \Rightarrow substs \ below \ body \ M end.
```

 $subst_hyp\ H$ substitutes the equality contained in H. The behaviour is extended in Lib-Data -TODO

```
match type of H with
  |?x = ?y \Rightarrow first [subst x | subst y]
  end.
Tactic Notation "subst_hyp" hyp(H) := subst_hyp_base\ H.
   intro_subst is a shorthand for intro H; subst_hyp H: it introduces and substitutes the
equality at the head of the current goal.
Tactic Notation "intro_subst" :=
  let H := fresh "TEMP" in intros H; subst\_hyp H.
   subst\_local substitutes all local definition from the context
Ltac subst\_local :=
  repeat match goal with H:=_{-}\vdash_{-}\Rightarrow subst H end.
   subst\_eq E takes an equality x = t and replace x with t everywhere in the goal
Ltac subst_eq_base E :=
  let H := fresh "TEMP" in lets H: E; subst_hyp H.
Tactic Notation "subst_eq" constr(E) :=
  subst_eq_base\ E.
```

29.6.8 Tactics to work with proof irrelevance

Require Import Prooflrrelevance.

Ltac $subst_hyp_base\ H:=$

 $pi_rewrite\ E$ replaces E of type Prop with a fresh unification variable, and is thus a practical way to exploit proof irrelevance, without writing explicitly rewrite ($proof_irrelevance\ E\ E'$). Particularly useful when E' is a big expression.

```
Ltac pi\_rewrite\_base\ E\ rewrite\_tac:= let E':= fresh in let T:= type\ of\ E in evar (E':T); rewrite\_tac\ (@proof\_irrelevance\ \_E\ E'); subst E'. Tactic Notation "pi\_rewrite" constr(E):= pi\_rewrite\_base\ E\ ltac:(\text{fun}\ X\Rightarrow \text{rewrite}\ X). Tactic Notation "pi\_rewrite" constr(E) "in" hyp(H):= pi\_rewrite\_base\ E\ ltac:(\text{fun}\ X\Rightarrow \text{rewrite}\ X) in H).
```

29.6.9 Proving equalities

fequal is a variation on f_equal which has a better behaviour on equalities between n-ary tuples.

```
Ltac fegual\_base :=
  let go := f_equal; [fequal_base] in
  match goal with
  |\vdash(\_,\_,\_)=(\_,\_,\_)\Rightarrow qo
   |\vdash(\_,\_,\_)=(\_,\_,\_)\Rightarrow qo

```

29.7.4 Inversion and injection with substitution –rough implementation

The tactics *inversions* and *injections* provided in this section are similar to *inverts* and *injects* except that they perform substitution on all equalities from the context and not only the ones freshly generated. The counterpart is that they have simpler implementations.

inversions keep H is the same as inversions H but it does not clear hypothesis H.

```
Tactic Notation "inversions" "keep" hyp(H) := inversion H; subst.
```

inversions H is a shortcut for inversion H followed by subst and clear H. It is a rough implementation of inverts keep H which behave badly when the proof context already contains equalities. It is provided in case the better implementation turns out to be too slow.

```
Tactic Notation "inversions" hyp(H) := inversion H; subst; clear H.
```

injections keep H is the same as injection H followed by intros and subst. It is a rough implementation of injects keep H which behave badly when the proof context already contains equalities, or when the goal starts with a forall or an implication.

```
Tactic Notation "injections" "keep" hyp(H) := injection H; intros; subst.
```

injections H is the same as injection H followed by intros and clear H and subst. It is a rough implementation of injects keep H which behave badly when the proof context already contains equalities, or when the goal starts with a forall or an implication.

```
Tactic Notation "injections" "keep" hyp(H) := injection H; clear H; intros; subst.
```

29.7.5 Case analysis

cases is similar to case_eq E except that it generates the equality in the context and not in the goal, and generates the equality the other way round. The syntax cases E as H allows specifying the name H of that hypothesis.

```
Tactic Notation "cases" constr(E) "as" ident(H) :=
```

```
let X := fresh "TEMP" in
  set (X := E) in *; def_{-}to_{-}eq_{-}sym \ X \ H \ E;
  destruct X.
Tactic Notation "cases" constr(E) :=
  let x := fresh "Eq" in cases E as H.
    case_if_post is to be defined later as a tactic to clean up goals.
Ltac case\_if\_post := idtac.
    case\_if looks for a pattern of the form if ?B then ?E1 else ?E2 in the goal, and perform
a case analysis on B by calling destruct B. It looks in the goal first, and otherwise in the
first hypothesis that contains and if statement. case_if in H can be used to specify which
hypothesis to consider. Syntaxes case_if as Eq and case_if in H as Eq allows to name the
hypothesis coming from the case analysis.
Ltac case\_if\_on\_tactic \ E \ Eq :=
  match type \ of \ E with
  |\{\_\}+\{\_\} \Rightarrow \text{destruct } E \text{ as } [Eq \mid Eq]
  \mid \_ \Rightarrow \mathtt{let}\ X := \mathtt{fresh}\ \mathtt{in}
           sets\_eq \leftarrow X \ Eq: \ E;
           destruct X
  end; case\_if\_post.
Tactic Notation "case_if_on" constr(E) "as" simple_intropattern(Eq) :=
  case\_if\_on\_tactic \ E \ Eq.

```

29.9 Decidable equality

decides_equality is the same as decide equality excepts that it is able to unfold definitions at head of the current goal.

```
Ltac decides_equality_tactic :=
  first [ decide equality | progress(unfolds); decides_equality_tactic ].
Tactic Notation "decides_equality" :=
  decides_equality_tactic.
```

29.10 Equivalence

iff H can be used to prove an equivalence $P \leftrightarrow Q$ and name H the hypothesis obtained in each case. The syntaxes iff and iff H1 H2 are also available to specify zero or two names. The tactic iff $\leftarrow H$ swaps the two subgoals, i.e. produces $(Q \rightarrow P)$ as first subgoal.

```
Lemma iff_intro_swap: \forall \ (P \ Q : \mathtt{Prop}), \ (Q \to P) \to (P \to Q) \to (P \leftrightarrow Q). Proof. intuition. Qed.

Tactic Notation "iff" simple\_intropattern(H1) \ simple\_intropattern(H2) := \ split; [ intros $H1 \mid intros $H2 ].

Tactic Notation "iff" simple\_intropattern(H) := \ iff \ H \ H.

Tactic Notation "iff" := \ let \ H := \ fresh \ "H" \ in \ iff \ H.

Tactic Notation "iff" := \ simple\_intropattern(H1) \ simple\_intropattern(H2) := \ apply \ iff\_intro\_swap; [ intros $H1 \mid intros \ H2 ].

Tactic Notation "iff" := \ iff \leftarrow H \ H.

Tactic Notation "iff" := \ iff \leftarrow H \ H.

Tactic Notation "iff" := \ iff \leftarrow H \ H.
```

29.11 N-ary Conjunctions and Disjunctions

```
N-ary Conjunctions Splitting in Goals
    Underlying implementation of splits.
Ltac splits\_tactic N :=
  \mathtt{match}\ N with
   | \bigcirc \Rightarrow fail
   SO\Rightarrow idtac
   | S?N' \Rightarrow split; [| splits\_tactic N']
   end.
Ltac\ unfold\_goal\_until\_conjunction :=
  match goal with
   |\vdash \_ \land \_ \Rightarrow idtac
   \bot \Rightarrow progress(unfolds); unfold\_goal\_until\_conjunction
   end.
Ltac qet\_term\_conjunction\_arity T :=
  match T with
   | \_ \land \_ \land \_ \land \_ \land \_ \land \_ \land \_ \Rightarrow constr:(8)
    - \land - \land - \land - \land - \land - \land - \Rightarrow constr:(7)
    \_ \land \_ \land \_ \land \_ \land \_ \land \_ \Rightarrow constr:(6)
    \_ \land \_ \land \_ \land \_ \land \_ \Rightarrow constr:(5)
    \_ \land \_ \land \_ \land \_ \Rightarrow constr:(4)
    \_ \land \_ \land \_ \Rightarrow constr:(3)
    \_ \land \_ \Rightarrow constr:(2)
    \_ \rightarrow ?T' \Rightarrow get\_term\_conjunction\_arity T'
   | \_ \Rightarrow let P := get\_head T in
             \mathtt{let}\ T' := \mathtt{eval}\ \mathtt{unfold}\ P\ \mathtt{in}\ T\ \mathtt{in}
             match T' with
              \mid T \Rightarrow \text{fail } 1
              | \_ \Rightarrow get\_term\_conjunction\_arity T'
              end
   end.
Ltac qet\_qoal\_conjunction\_arity :=
  match goal with \vdash ?T \Rightarrow get\_term\_conjunction\_arity\ T end.
    splits applies to a goal of the form (T1 \wedge ... \wedge TN) and destruct it into N subgoals T1
.. TN. If the goal is not a conjunction, then it unfolds the head definition.
Tactic Notation "splits" :=
```

```
unfold\_goal\_until\_conjunction;
let N := get\_goal\_conjunction\_arity in splits\_tactic\ N.
```

splits N is similar to splits, except that it will unfold as many definitions as necessary to obtain an N-ary conjunction.

```
Tactic Notation "splits" constr(N) := let N := nat\_from\_number \ N in splits\_tactic \ N.
```

splits_all will recursively split any conjunction, unfolding definitions when necessary. Warning: this tactic will loop on goals of the form *well_founded R*. Todo: fix this

```
Ltac splits\_all\_base := \texttt{repeat split}.
```

```
Tactic Notation "splits_all" := splits\_all\_base.
```

N-ary Conjunctions Deconstruction Underlying implementation of *destructs*.

 $Ltac \ destructs_conjunction_tactic \ N \ T :=$

```
\begin{array}{l} \operatorname{match} \ N \ \operatorname{with} \\ \mid 2 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ ?] \\ \mid 3 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ ?]] \\ \mid 4 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ [? \ ?]]]] \\ \mid 5 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ [? \ [? \ ?]]]]] \\ \mid 6 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ [? \ [? \ [? \ ?]]]]]] \\ \mid 7 \Rightarrow \operatorname{destruct} \ T \ \operatorname{as} \ [? \ [? \ [? \ [? \ [? \ ?]]]]]] \\ \operatorname{end}. \end{array}
```

destructs T allows destructing a term T which is a N-ary conjunction. It is equivalent to destruct T as (H1 ... HN), except that it does not require to manually specify N different names.

```
Tactic Notation "destructs" constr(T) := let TT := type \ of \ T in let N := get\_term\_conjunction\_arity \ TT in destructs\_conjunction\_tactic \ N \ T.
```

destructs N T is equivalent to destruct T as $(H1 \dots HN)$, except that it does not require to manually specify N different names. Remark that it is not restricted to N-ary conjunctions.

```
Tactic Notation "destructs" constr(N) constr(T) := let N := nat\_from\_number N in destructs\_conjunction\_tactic N T.

Proving goals which are N-ary disjunctions
```

Underlying implementation of branch.

```
Ltac branch\_tactic \ K \ N :=
  match constr: (K, N) with
   (-,0) \Rightarrow \text{fail } 1
    (0, \_) \Rightarrow \text{fail } 1
    (1,1) \Rightarrow idtac
   (1,_) \Rightarrow left
   (S?K', S?N') \Rightarrow right; branch_tactic K'N'
Ltac\ unfold\_goal\_until\_disjunction :=
  match goal with
   | \vdash \_ \lor \_ \Rightarrow idtac
   | \_ \Rightarrow progress(unfolds); unfold\_goal\_until\_disjunction
   end.
Ltac get\_term\_disjunction\_arity\ T :=
   {\tt match}\ T\ {\tt with}
   | \_ \lor \_ \lor \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(8)
   | \_ \lor \_ \lor \_ \lor \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(7)
    \_ \lor \_ \lor \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(6)
    \_ \lor \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(5)
    \_ \lor \_ \lor \_ \lor \_ \Rightarrow constr:(4)
    \_ \lor \_ \lor \_ \Rightarrow constr:(3)
    _{-} \lor _{-} \Rightarrow constr:(2)
    \_ \rightarrow ?T' \Rightarrow get\_term\_disjunction\_arity\ T'
    \_\Rightarrow let P:=get\_head\ T in
             let T' := \text{eval unfold } P \text{ in } T \text{ in}
             match T' with
             \mid T \Rightarrow \text{fail } 1
             | \_ \Rightarrow qet\_term\_disjunction\_arity T'
             end
   end.
Ltac get\_goal\_disjunction\_arity :=
  match goal with \vdash ?T \Rightarrow get\_term\_disjunction\_arity\ T end.
    branch N applies to a goal of the form P1 \vee ... \vee PK \vee ... \vee PN and leaves the goal PK.
It only able to unfold the head definition (if there is one), but for more complex unfolding
one should use the tactic branch K of N.
Tactic Notation "branch" constr(K) :=
   let K := nat\_from\_number K in
   unfold_goal_until_disjunction;
   let N := get\_goal\_disjunction\_arity in
   branch\_tactic \ K \ N.
    branch K of N is similar to branch K except that the arity of the disjunction N is given
```

manually, and so this version of the tactic is able to unfold definitions. In other words, applies to a goal of the form $P1 \vee ... \vee PK \vee ... \vee PN$ and leaves the goal PK.

```
Tactic Notation "branch" constr(K) "of" constr(N) :=
  let N := nat\_from\_number \ N in
  let K := nat\_from\_number K in
  branch\_tactic\ K\ N.
    N-ary Disjunction Deconstruction
    Underlying implementation of branches.
Ltac destructs\_disjunction\_tactic\ N\ T:=
  \mathtt{match}\ N with
    2 \Rightarrow \text{destruct } T \text{ as } [? \mid ?]
  | 3 \Rightarrow \text{destruct } T \text{ as } [? | [? | ?]]
    \mid 4 \Rightarrow \text{destruct } T \text{ as } [? \mid [? \mid [? \mid ?]]]
    | 5 \Rightarrow \text{destruct } T \text{ as } [? \mid [? \mid [? \mid [? \mid ?]]]]
    end.
    branches T allows destructing a term T which is a N-ary disjunction. It is equivalent to
destruct T as [H1 \mid ... \mid HN], and produces N subgoals corresponding to the N possible
cases.
Tactic Notation "branches" constr(T) :=
  let TT := type \ of \ T in
  let N := qet\_term\_disjunction\_arity\ TT in
  destructs\_disjunction\_tactic\ N\ T.
    branches N T is the same as branches T except that the arity is forced to N. This version
is useful to unfold definitions on the fly.
Tactic Notation "branches" constr(N) constr(T) :=
  let N := nat\_from\_number \ N in
  destructs\_disjunction\_tactic\ N\ T.
    N-ary Existentials
Ltac get\_term\_existential\_arity\ T:=
  match T with
    \exists x1 \ x2 \ x3 \ x4 \ x5 \ x6 \ x7 \ x8, \Rightarrow constr:(8)

  let N := nat\_from\_number \ N in aux \ N.
Tactic Notation "exists___" :=
  let N := qet\_goal\_existential\_arity in
```

29.12 Tactics to prove typeclass instances

typeclass is an automation tactic specialized for finding typeclass instances.

```
Tactic Notation "typeclass" := let go = := eauto with typeclass\_instances in solve [ go \ tt | constructor; go \ tt ]. solve\_typeclass is a simpler version of typeclass, to use in hint tactics for resolving instances

Tactic Notation "solve\_typeclass" := solve [ eauto with typeclass\_instances ].
```

29.13 Tactics to invoke automation

29.13.1 jauto, a new automation tactics

jauto is better at intuition eauto because it can open existentials from the context. In the same time, jauto can be faster than intuition eauto because it does not destruct disjunctions from the context. The strategy of jauto can be summarized as follows:

- open all the existentials and conjunctions from the context
- call esplit and split on the existentials and conjunctions in the goal
- call eauto.

```
Ltac jauto\_set\_hyps :=
  repeat match goal with H: ?T \vdash \_ \Rightarrow
     {\tt match}\ T\ {\tt with}
     | \_ \land \_ \Rightarrow \text{destruct } H
      \mid \exists \ a , _{\bot} \Rightarrow \mathtt{destruct} \ H
     | \_ \Rightarrow generalizes H
     end
  end.
Ltac jauto\_set\_goal :=
  repeat match goal with
  |\vdash \exists \ a, \ \_ \Rightarrow esplit
  |\vdash \_ \land \_ \Rightarrow split
  end.
Ltac jauto\_set :=
  intros; jauto_set_hyps;
  intros; jauto_set_goal;
  unfold not in *.
Tactic Notation "jauto" :=
  try solve [ jauto_set; eauto ].
Tactic Notation "jauto_fast" :=
  try solve [ auto | eauto | jauto ].
iauto is a shorthand for intuition eauto
Tactic Notation "iauto" := try solve [intuition eauto].
```

29.13.2 Definitions of automation tactics

The two following tactics defined the default behaviour of "light automation" and "strong automation". These tactics may be redefined at any time using the syntax Ltac .. ::= ... $auto_tilde$ is the tactic which will be called each time a symbol \neg is used after a tactic.

```
Ltac auto\_tilde\_default := auto.

Ltac auto\_tilde := auto\_tilde\_default.

auto\_star is the tactic which will be called each time a symbol \times is used after a tactic.

Ltac auto\_star\_default := try solve [ auto | eauto | intuition eauto ].

Ltac auto\_star := auto\_star\_default.
```

auto \neg is a notation for tactic *auto_tilde*. It may be followed by lemmas (or proofs terms) which auto will be able to use for solving the goal.

```
Tactic Notation "auto" "^{\sim}" := auto\_tilde.
Tactic Notation "auto" "^{\sim}" constr(E1) :=
```

```
lets: E1; auto_tilde.
Tactic Notation "auto" "^{"}" constr(E1) constr(E2) :=
  lets: E1; lets: E2; auto_tilde.
Tactic Notation "auto" "^{\sim}" constr(E1) constr(E2) constr(E3) :=
  lets: E1; lets: E2; lets: E3; auto_tilde.
   auto × is a notation for tactic auto_star. It may be followed by lemmas (or proofs terms)
which auto will be able to use for solving the goal.
Tactic Notation "auto" "*" :=
  auto\_star.
Tactic Notation "auto" "*" constr(E1) :=
  lets: E1; auto_star.
Tactic Notation "auto" "*" constr(E1) constr(E2) :=
  lets: E1; lets: E2; auto_star.
Tactic Notation "auto" "*" constr(E1) constr(E2) constr(E3) :=
  lets: E1; lets: E2; lets: E3; auto_star.
   auto_false is a version of auto able to spot some contradictions.
                                                                            auto\_false \neg and
auto\_false \times are also available.
Ltac auto\_false\_base\ cont:=
  try solve | cont tt | tryfalse by congruence/
              | try split; intros\_all; tryfalse by congruence/ ].
Tactic Notation "auto_false" :=
   auto\_false\_base ltac:(fun tt \Rightarrow auto).
Tactic Notation "auto_false" "~" :=
   auto\_false\_base\ ltac:(fun\ tt \Rightarrow auto~).
Tactic Notation "auto_false" "*" :=
   auto\_false\_base ltac:(fun tt \Rightarrow auto^*).
```

29.13.3 Definitions for parsing compatibility

```
Tactic Notation "f_equal" :=
  f_equal.
Tactic Notation "constructor" :=
  constructor.
Tactic Notation "simple" :=
  simpl.
```

29.13.4 Parsing for light automation

Any tactic followed by the symbol \neg will have $auto_tilde$ called on all of its subgoals. Three exceptions:

- cuts and asserts only call auto on their first subgoal,
- apply relies on *sapply* rather than apply,
- tryfalse¬ is defined as tryfalse by auto_tilde.

Some builtin tactics are not defined using tactic notations and thus cannot be extended, e.g. simpl and unfold. For these, notation such as simpl¬ will not be available.

```

29.13.5 Parsing for strong automation

Any tactic followed by the symbol \times will have auto \times called on all of its subgoals. The exceptions to these rules are the same as for light automation.

Exception: use $subs \times instead$ of $subst \times if$ you import the library Coq. Classes. Equivalence.

Tactic Notation "show_def" :=
  unfold ltac_something.
Tactic Notation "show_def" "in" "*" :=
  unfold ltac_something in *.
   hide_defs and show_defs applies to all definitions
Tactic Notation "hide_defs" :=
  repeat match goal with H := ?T \vdash \_ \Rightarrow
```

```
{\tt match}\ T\ {\tt with}
      @ltac_something \_ \ \Rightarrow  fail 1
     \mid \_ \Rightarrow change T with (@ltac_something \_ T) in H
     end
  end.
Tactic Notation "show_defs" :=
  repeat match goal with H := (@ltac\_something \_ ?T) \vdash \_ \Rightarrow
     change (@ltac_something _{-} T) with T in H end.
   hide_hyp\ H replaces the type of H with the notation Something and show_hyp\ H reveals
the type of the hypothesis. Note that the hidden type of H remains convertible the real type
of H.
Tactic Notation "show_hyp" hyp(H) :=
  apply ltac\_something\_show in H.
Tactic Notation "hide-hyp" hyp(H) :=
  apply ltac\_something\_hide in H.
   hide_hyps and show_hyps can be used to hide/show all hypotheses of type Prop.
Tactic Notation "show_hyps" :=
  repeat match goal with
     H: @ltac\_something \_ \_ \vdash \_ \Rightarrow show\_hyp \ H \ end.
Tactic Notation "hide_hyps" :=
  repeat match goal with H: ?T \vdash \bot \Rightarrow
    match type of T with
    | \text{Prop} \Rightarrow
       {\tt match}\ T\ {\tt with}
        @ltac_something \_ \ \Rightarrow  fail 2
       | \_ \Rightarrow hide\_hyp H
       end
    |  \Rightarrow fail 1
    end
  end.
   hide H and show H automatically select between hide_hyp or hide_def, and show_hyp or
show_def. Similarly hide_all and show_all apply to all.
Tactic Notation "hide" hyp(H) :=
  first [hide\_def \ H \mid hide\_hyp \ H].
Tactic Notation "show" hyp(H) :=
  first [show\_def \ H \mid show\_hyp \ H].
Tactic Notation "hide_all" :=
  hide_hyps; hide_defs.
Tactic Notation "show_all" :=
```

```
unfold ltac_something in *.
```

 $hide_term\ E$ can be used to hide a term from the goal. $show_term$ or $show_term\ E$ can be used to reveal it. $hide_term\ E$ in H can be used to specify an hypothesis.

```
Tactic Notation "hide_term" \operatorname{constr}(E) := \operatorname{change} E with (@ltac_something _ E).

Tactic Notation "show_term" \operatorname{constr}(E) := \operatorname{change} (@ltac_something _ E) with E.

Tactic Notation "show_term" := \operatorname{unfold} \operatorname{ltac\_something}.

Tactic Notation "hide_term" \operatorname{constr}(E) "in" \operatorname{hyp}(H) := \operatorname{change} E with (@ltac_something _ E) in E.

Tactic Notation "show_term" \operatorname{constr}(E) "in" \operatorname{hyp}(E) := \operatorname{change} (E) with E in E.

Tactic Notation "show_term" "in" \operatorname{hyp}(E) := \operatorname{unfold} \operatorname{ltac\_something} E.
```

29.14.2 Sorting hypotheses

sort sorts out hypotheses from the context by moving all the propositions (hypotheses of type Prop) to the bottom of the context.

```
Ltac sort\_tactic :=
try match goal with H: ?T \vdash \_ \Rightarrow
match type \ of \ T with Prop \Rightarrow
generalizes \ H; \ (try \ sort\_tactic); \ intro
end end.

Tactic Notation "sort" :=
sort\_tactic.
```

29.14.3 Clearing hypotheses

clears X1 ... XN is a variation on clear which clears the variables X1..XN as well as all the hypotheses which depend on them. Contrary to clear, it never fails.

```
Tactic Notation "clears" ident(X1) :=  let rec\ doit\ \_ :=  match goal with |\ H: \mathtt{context}[X1] \vdash \_ \Rightarrow \mathtt{clear}\ H; \ \mathtt{try}\ (doit\ tt)  |\ \_ \Rightarrow \mathtt{clear}\ X1  end in doit\ tt.
Tactic Notation "clears" ident(X1)\ ident(X2) :=  clears\ X1;\ clears\ X2.
Tactic Notation "clears" ident(X1)\ ident(X2)\ ident(X3) :=
```

```
clears X1; clears X2; clear X3.
Tactic Notation "clears" ident(X1) \ ident(X2) \ ident(X3) \ ident(X4) :=
  clears X1; clears X2; clear X3; clear X4.
Tactic Notation "clears" ident(X1) ident(X2) ident(X3) ident(X4)
 ident(X5) :=
  clears X1; clear X2; clear X3; clear X4; clear X5.
Tactic Notation "clears" ident(X1) ident(X2) ident(X3) ident(X4)
 ident(X5) \ ident(X6) :=
  clears X1; clear X2; clear X3; clear X4; clear X5; clear X6.
   clears (without any argument) clears all the unused variables from the context. In other
words, it removes any variable which is not a proposition (i.e. not of type Prop) and which
does not appear in another hypothesis nor in the goal.
Ltac clears\_tactic :=
  match goal with H: ?T \vdash \_ \Rightarrow
  match type of T with
  | Prop \Rightarrow generalizes H; (try clears_tactic); intro
   ?TT \Rightarrow clear H; (try clears\_tactic)
  |?TT \Rightarrow generalizes H; (try clears_tactic); intro
  end end.
Tactic Notation "clears" :=
  clears\_tactic.
   clears_all clears all the hypotheses from the context that can be cleared. It leaves only
the hypotheses that are mentioned in the goal.
Tactic Notation "clears_all" :=
  repeat match goal with H: \_ \vdash \_ \Rightarrow \text{clear } H \text{ end.}
   clears_last clears the last hypothesis in the context. clears_last N clears the last N
hypotheses in the context.
Tactic Notation "clears_last" :=
  match goal with H: ?T \vdash \bot \Rightarrow \text{clear } H \text{ end.}
Ltac clears\_last\_base\ N :=
  match nat\_from\_number\ N with
  \mid 0 \Rightarrow idtac
  | S ? p \Rightarrow clears\_last; clears\_last\_base p
```

end.

 $clears_last_base\ N.$

Tactic Notation "clears_last" constr(N) :=

29.15 Tactics for development purposes

29.15.1 Skipping subgoals

The *skip* tactic can be used at any time to admit the current goal. Using *skip* is much more efficient than using the *Focus* top-level command to reach a particular subgoal.

There are two possible implementations of *skip*. The first one relies on the use of an existential variable. The second one relies on an axiom of type *False*. Remark that the builtin tactic *admit* is not applicable if the current goal contains uninstantiated variables.

The advantage of the first technique is that a proof using *skip* must end with *Admitted*, since Qed will be rejected with the message "*uninstantiated existential variables*". It is thereafter clear that the development is incomplete.

The advantage of the second technique is exactly the converse: one may conclude the proof using Qed, and thus one saves the pain from renaming Qed into Admitted and vice-versa all the time. Note however, that it is still necessary to instantiate all the existential variables introduced by other tactics in order for Qed to be accepted.

The two implementation are provided, so that you can select the one that suits you best. By default skip' uses the first implementation, and skip uses the second implementation.

```
Ltac skip\_with\_existential :=
match goal with \vdash ?G \Rightarrow
let H := fresh in evar(H:G); eexact H end.
Variable skip\_axiom :=
elimtype False; apply <math>skip\_axiom.
Tactic Notation "skip" :=
skip\_with\_axiom.
Tactic Notation "skip'" :=
skip\_with\_existential.
```

 $skip\ H$: T adds an assumption named H of type T to the current context, blindly assuming that it is true. skip: T and $skip\ H_asserts$: T and $skip_asserts$: T are other possible syntax. Note that H may be an intro pattern. The syntax $skip\ H1$.. HN: T can be used when T is a conjunction of N items.

```
Tactic Notation "skip" simple\_intropattern(I) ":" constr(T) := asserts\ I:\ T;\ [\ skip\ |\ ].
Tactic Notation "skip" ":" constr(T) := let\ H := fresh\ in\ skip\ H:\ T.
Tactic Notation "skip" simple\_intropattern(I1) simple\_intropattern(I2) ":" constr(T) := skip\ [I1\ I2]:\ T.
Tactic Notation "skip" simple\_intropattern(I1) simple\_intropattern(I2) simple\_intropattern(I3) ":" constr(T) := simple\_intropattern(I2) simple\_intropattern(I3) ":" constr(T) := simple\_intropattern(I3) ":"
```

```
skip [11 [12 13]]: T.
Tactic Notation "skip" simple\_intropattern(I1)
 simple\_intropattern(I2) \ simple\_intropattern(I3)
 simple\_intropattern(I_4) ":" constr(T) :=
  skip [11 [12 [13 14]]]: T.
Tactic Notation "skip" simple\_intropattern(I1)
 simple\_intropattern(I2) simple\_intropattern(I3)
 simple\_intropattern(I_4) \ simple\_intropattern(I_5) \ ":" \ constr(T) :=
  skip [11 [12 [13 [14 15]]]]: T.
Tactic Notation "skip" simple\_intropattern(I1)
 simple\_intropattern(I2) \ simple\_intropattern(I3)
 simple\_intropattern(I_4) simple\_intropattern(I_5)
 simple\_intropattern(I6) ":" constr(T) :=
  skip [I1 [I2 [I3 [I4 [I5 I6]]]]]: T.
Tactic Notation "skip_asserts" simple_intropattern(I) ":" constr(T) :=
  skip I: T.
Tactic Notation "skip_asserts" ":" constr(T) :=
  skip: T.
   skip\_cuts \ T simply replaces the current goal with T.
Tactic Notation "skip_cuts" constr(T) :=
  cuts: T; | skip | |.
   skip_qoal H applies to any goal. It simply assumes the current goal to be true. The
assumption is named "H". It is useful to set up proof by induction or coinduction. Syntax
skip_goal is also accepted.
Tactic Notation "skip\_goal" ident(H) :=
  match goal with \vdash ?G \Rightarrow skip \ H : G end.
Tactic Notation "skip_goal" :=
  let IH := fresh "IH" in skip\_goal IH.
   skip\_rewrite\ T can be applied when T is an equality. It blindly assumes this equality to
be true, and rewrite it in the goal.
Tactic Notation "skip_rewrite" constr(T) :=
  let M := fresh in skip\_asserts M: T; rewrite M; clear M.
   skip\_rewrite\ T in H is similar as rewrite\_skip, except that it rewrites in hypothesis H.
Tactic Notation "skip_rewrite" constr(T) "in" hyp(H) :=
  let M := fresh in skip\_asserts \ M : \ T; rewrite M in H; clear M.
   skip_rewrites_all T is similar as rewrite_skip, except that it rewrites everywhere (goal
and all hypotheses).
Tactic Notation "skip_rewrite_all" constr(T) :=
  let M := fresh in skip\_asserts M: T; rewrite\_all M; clear M.
```

 $skip_induction\ E$ applies to any goal. It simply assumes the current goal to be true (the assumption is named "IH" by default), and call **destruct** E instead of **induction** E. It is useful to try and set up a proof by induction first, and fix the applications of the induction hypotheses during a second pass on the proof.

```
Tactic Notation "skip_induction" constr(E) := let IH := fresh "IH" in skip\_goal IH; destruct E.

Tactic Notation "skip_induction" constr(E) "as" simple\_intropattern(I) := let IH := fresh "IH" in skip\_goal IH; destruct E as I.
```

29.16 Compatibility with standard library

The module *Program* contains definitions that conflict with the current module. If you import *Program*, either directly or indirectly (e.g. through *Setoid* or *ZArith*), you will need to import the compability definitions through the top-level command: Require Import *LibTacticsCompatibility*.

```
Module LIBTACTICSCOMPATIBILITY.
  Tactic Notation "apply" "*" constr(H) :=
        sapply H; auto_star.
  Tactic Notation "subst" "*" :=
        subst; auto_star.
End LIBTACTICSCOMPATIBILITY.
Open Scope nat_scope.
```

Chapter 30

Library UseTactics

30.1 UseTactics: Tactic Library for Coq: A Gentle Introduction

Coq comes with a set of builtin tactics, such as reflexivity, intros, inversion and so on. While it is possible to conduct proofs using only those tactics, you can significantly increase your productivity by working with a set of more powerful tactics. This chapter describes a number of such very useful tactics, which, for various reasons, are not yet available by default in Coq. These tactics are defined in the *LibTactics.v* file.

Require Import LibTactics.

Remark: SSReflect is another package providing powerful tactics. The library "LibTactics" differs from "SSReflect" in two respects:

- "SSReflect" was primarily developed for proving mathematical theorems, whereas "Lib-Tactics" was primarily developed for proving theorems on programming languages. In particular, "LibTactics" provides a number of useful tactics that have no counterpart in the "SSReflect" package.
- "SSReflect" entirely rethinks the presentation of tactics, whereas "LibTactics" mostly stick to the traditional presentation of Coq tactics, simply providing a number of additional tactics. For this reason, "LibTactics" is probably easier to get started with than "SSReflect".

This chapter is a tutorial focusing on the most useful features from the "LibTactics" library. It does not aim at presenting all the features of "LibTactics". The detailed specification of tactics can be found in the source file LibTactics.v. Further documentation as well as demos can be found at http://www.chargueraud.org/softs/tlc/.

In this tutorial, tactics are presented using examples taken from the core chapters of the "Software Foundations" course. To illustrate the various ways in which a given tactic can be used, we use a tactic that duplicates a given goal. More precisely, dup produces two copies of the current goal, and dup n produces n copies of it.

30.2 Tactics for introduction and case analysis

This section presents the following tactics:

- *introv*, for naming hypotheses more efficiently,
- *inverts*, for improving the inversion tactic,
- cases, for performing a case analysis without losing information,
- cases_if, for automating case analysis on the argument of if.

30.2.1 The tactic introv

Module IntrovExamples.

Require Import Stlc.

Import Imp STLC.

The tactic *introv* allows to automatically introduce the variables of a theorem and explicitly name the hypotheses involved. In the example shown next, the variables c, st, st1 and st2 involved in the statement of determinism need not be named explicitly, because their name where already given in the statement of the lemma. On the contrary, it is useful to provide names for the two hypotheses, which we name E1 and E2, respectively.

Theorem ceval_deterministic: $\forall c \ st \ st1 \ st2$,

```
c / st \mid \mid st1 \rightarrow c / st \mid \mid st2 \rightarrow st1 = st2.
```

Proof.

Proof.

introv E1 E2. Admitted.

When there is no hypothesis to be named, one can call *introv* without any argument.

```
Theorem dist_exists_or: \forall (X: \texttt{Type}) (P \ Q: X \to \texttt{Prop}), (\exists \ x, \ P \ x \lor Q \ x) \leftrightarrow (\exists \ x, \ P \ x) \lor (\exists \ x, \ Q \ x). Proof.
```

introv. Admitted.

The tactic *introv* also applies to statements in which \forall and \rightarrow are interleaved.

```
Theorem ceval_deterministic': \forall c \ st \ st1, (c \ / \ st \ | \ | \ st1) \rightarrow \forall \ st2, (c \ / \ st \ | \ | \ st2) \rightarrow st1 = st2.
```

introv E1 E2. Admitted.

Like the arguments of intros, the arguments of introv can be structured patterns.

Theorem exists_impl: forall X (P : X -> Prop) (Q : Prop) (R : Prop), (forall x, P x -> Q) -> ((exists x : X, P x) -> Q). Proof. introv x H2. eauto. Qed.

Remark: the tactic *introv* works even when definitions need to be unfolded in order to reveal hypotheses.

End Introvexamples.

30.2.2 The tactic *inverts*

```
Module InvertsExamples. Require Import Stlc Equiv Imp. Import STLC.
```

The inversion tactic of Coq is not very satisfying for three reasons. First, it produces a bunch of equalities which one typically wants to substitute away, using subst. Second, it introduces meaningless names for hypotheses. Third, a call to inversion H does not remove H from the context, even though in most cases an hypothesis is no longer needed after being inverted. The tactic *inverts* address all of these three issues. It is intented to be used in place of the tactic inversion.

The following example illustrates how the tactic *inverts* H behaves mostly like **inversion** H except that it performs some substitutions in order to eliminate the trivial equalities that are being produced by **inversion**.

```
Theorem skip_left: \forall c,
  cequiv (SKIP; c) c.
Proof.
  introv. split; intros H.
          inversion H. subst. inversion H2. subst. assumption.
  inverts H. inverts H2. assumption.
Admitted.
   A slightly more interesting example appears next.
Theorem ceval_deterministic: \forall c \ st \ st1 \ st2,
  c / st \mid \mid st1 \rightarrow
  c / st \mid \mid st2 \rightarrow
  st1 = st2.
Proof.
  introv E1 E2. generalize dependent st2.
  (ceval\_cases (induction E1) Case); intros st2 E2.
                    dup. inversion E2. subst. admit.
  admit. admit.
```

The tactic *inverts* H as. is like *inverts* H except that the variables and hypotheses being produced are placed in the goal rather than in the context. This strategy allows naming those new variables and hypotheses explicitly, using either intros or *introv*.

Theorem ceval_deterministic': $\forall c \ st \ st1 \ st2$,

inverts E2. admit.

Admitted.

```
c / st \mid \mid st1 \rightarrow
  c / st \mid \mid st2 \rightarrow
  st1 = st2.
Proof.
  introv E1 E2. generalize dependent st2.
  (ceval\_cases (induction E1) Case); intros st2 E2;
    inverts E2 as.
  Case "E_Skip". reflexivity.
  Case "E_Ass".
   subst n.
    reflexivity.
  Case "E_Seq".
   intros st3 Red1 Red2.
    assert (st' = st3) as EQ1.
       SCase "Proof of assertion". apply IHE1_1; assumption.
    subst st3.
    apply IHE1_2. assumption.
  Case "E_IfTrue".
    SCase "b1 evaluates to true".
   intros.
       apply IHE1. assumption.
    SCase "b1 evaluates to false (contradiction)".
      rewrite H in H5. inversion H5.
Admitted.
```

In the particular case where a call to inversion produces a single subgoal, one can use the syntax *inverts* H as H1 H2 H3 for calling *inverts* and naming the new hypotheses H1, H2 and H3. In other words, the tactic *inverts* H as H1 H2 H3 is equivalent to *inverts* H as; *introv* H1 H2 H3. An example follows.

```
Theorem skip_left': \forall c, cequiv (SKIP; c) c.

Proof.

introv. split; intros H.

inverts\ H as U\ V. inverts\ U. assumption.

Admitted.
```

A more involved example appears next. In particular, this example shows that the name of the hypothesis being inverted can be reused.

```
Example typing_nonexample_1 :
¬∃ T,
has_type empty
(tabs x TBool
```

```
(tabs y TBool
                (tapp (tvar x) (tvar y))))
         T.
Proof.
  dup 3.
  intros C. destruct C.
  inversion H. subst. clear H.
  inversion H5. subst. clear H5.
  inversion H4. subst. clear H4.
  inversion H2. subst. clear H2.
  inversion H5. subst. clear H5.
  inversion H1.
  intros C. destruct C.
  inverts H as H1.
  inverts H1 as H2.
  inverts H2 as H3.
  inverts H3 as H4.
  inverts H4.
  intros C. destruct C.
  inverts H as H.
  inverts H as H.
  inverts H as H.
  inverts H as H.
  inverts H.
Qed.
```

End INVERTSEXAMPLES.

Note: in the rare cases where one needs to perform an inversion on an hypothesis H without clearing H from the context, one can use the tactic *inverts keep* H, where the keyword keep indicates that the hypothesis should be kept in the context.

30.2.3 The tactics cases and cases_if

```
Module CASESEXAMPLE. Require Import Stlc. Import STLC.
```

As you probably have learned, the tactic destruct can be used to perform a case analysis. However, this tactic sometimes destroys useful information. The tactic remember is intended to introduce an equality that avoids destruct loosing such useful information. The tactic cases provided by LibTactics packages remember and destruct together in order to shorten proof scripts.

The tactic cases E behaves like remember E as x; destruct x, only with the difference that it generates the symmetric of the equality produced by remember. For example, cases would produce the equality beq_id k1 k2 = true rather than the equality $true = beq_id$ k1 k2. Indeed, the former reads much more naturally than the latter. Moreover, the syntax cases E as H allows to involve the cases tactic by specifying how to name the equality generated.

Remark: cases is quite similar to $case_eq$. For the sake of compatibility with remember and $case_eq$, the library "LibTactics" provides a tactic called cases that generates exactly the same equalities as remember or $case_eq$ would, i.e., producing an equality in the form $true = beq_id \ k1 \ k2$ rather than $beq_id \ k1 \ k2 = true$. The following examples illustrate the behavior of the tactic cases' E as H.

```
Theorem update_same : \forall \ x1 \ k1 \ k2 \ (f: state), f \ k1 = x1 \rightarrow (update f \ k1 \ x1) k2 = f \ k2.

Proof.

intros x1 \ k1 \ k2 \ f \ Heq.

unfold update. subst. dup.

remember (beq_id k1 \ k2) as b. destruct b.

apply beq_id_eq in Heqb. subst. reflexivity. reflexivity.

cases (beq_id k1 \ k2) as E.

apply beq_id_eq in E. subst. reflexivity. reflexivity.
```

The tactic *cases_if* is a tactic that allows performing a case analysis without having to explicitly specify which value the case analysis should be upon. More precisely, the tactic *cases_if* looks in the goal or in the context for an expression of the form if *E* then .. else ..., and it invokes *cases E*. Remark: if there are several possibilities, *cases_if* only consider the first one.

The tactic *cases_if* thus saves the need to copy-past an expression that occurs in the current proof obligation, leading to shorter and more robust proof scripts.

Here again, for compatibility reasons, the library provides a tactic called $cases_if$ '. Moreover, one may write $cases_if$ as H or $cases_if$ ' as H for specifying the name to use for the generated equality.

```
Theorem update_same': \forall x1 \ k1 \ k2 \ (f: state), f \ k1 = x1 \rightarrow (update f \ k1 \ x1) \ k2 = f \ k2. Proof. intros x1 \ k1 \ k2 \ f \ Heq. unfold update. subst.
```

```
cases_if' as E.
    apply beq_id_eq in E. subst. reflexivity.
    reflexivity.
Qed.
End CASESEXAMPLE.
```

30.3 Tactics for n-ary connectives

Because Coq encodes conjunctions and disjunctions using binary constructors \land and \lor , working with a conjunction or a disjunction of N facts can sometimes be quite cumbursome. For this reason, "LibTactics" provides tactics offering direct support for n-ary conjunctions and disjunctions. It also provides direct support for n-ary existententials.

This section presents the following tactics:

- splits for decomposing n-ary conjunctions,
- branch for decomposing n-ary disjunctions,
- \exists for proving n-ary existentials.

```
Module NARYEXAMPLES.
Require Import References SfLib.
Import STLCRef.
```

30.3.1 The tactic splits

The tactic *splits* applies to a goal made of a conjunction of n propositions and it produces n subgoals. For example, it decomposes the goal $G1 \wedge G2 \wedge G3$ into the three subgoals G1, G2 and G3.

```
Lemma demo_splits : \forall n m, n > 0 \land n < m \land m < n+10 \land m \neq 3. Proof. intros. splits. Admitted.
```

30.3.2 The tactic branch

The tactic branch k can be used to prove a n-ary disjunction. For example, if the goal takes the form $G1 \vee G2 \vee G3$, the tactic branch 2 leaves only G2 as subgoal. The following example illustrates the behavior of the branch tactic.

```
Lemma demo_branch : \forall n m, n < m \lor n = m \lor m < n.
```

```
Proof. intros. destruct (lt\_eq\_lt\_dec \ n \ m) as [[H1|H2]|H3]. branch 1. apply H1. branch 2. apply H2. branch 3. apply H3. Qed.
```

30.3.3 The tactic \exists

The library "LibTactics" introduces a notation for n-ary existentials. For example, one can write $\exists x \ y \ z$, H instead of $\exists x, \exists y, \exists z, H$. Similarly, the library provides a n-ary tactic $\exists a \ b \ c$, which is a shorthand for $\exists a; \exists b; \exists c$. The following example illustrates both the notation and the tactic for dealing with n-ary existentials.

```
Theorem progress: \forall ST \ t \ T \ st,
  has_type empty ST\ t\ T \rightarrow
  store_well_typed ST st \rightarrow
  value t \vee \exists t' st', t / st ==> t' / st'.
Proof with eauto.
  intros ST t T st Ht HST. remember (@empty ty) as Gamma.
  (has_type_cases (induction Ht) Case); subst; try solve by inversion...
  Case "T_App".
     right. destruct IHHt1 as [Ht1p \mid Ht1p]...
     SCase "t1 is a value".
       inversion Ht1p; subst; try solve by inversion.
       destruct IHHt2 as [Ht2p \mid Ht2p]...
       SSCase "t2 steps".
         inversion Ht2p as [t2' [st' Hstep]].
         \exists (tapp (tabs x \ T \ t) \ t2') st'...
Admitted.
```

Remark: a similar facility for n-ary existentials is provided by the module *Coq.Program.Syntax* from the standard library. (*Coq.Program.Syntax* supports existentials up to arity 4; *LibTactics* supports them up to arity 10.

End NARYEXAMPLES.

30.4 Tactics for working with equality

One of the major weakness of Coq compared with other interactive proof assistants is its relatively poor support for reasoning with equalities. The tactics described next aims at simplifying pieces of proof scripts manipulating equalities.

This section presents the following tactics:

- asserts_rewrite for introducing an equality to rewrite with,
- cuts_rewrite, which is similar except that its subgoals are swapped,
- substs for improving the subst tactic,
- fequals for improving the f_equal tactic,
- $applys_eq$ for proving $P \ x \ y$ using an hypothesis $P \ x \ z$, automatically producing an equality y = z as subgoal.

Module EQUALITYEXAMPLES.

30.4.1 The tactics asserts_rewrite and cuts_rewrite

The tactic asserts_rewrite (E1 = E2) replaces E1 with E2 in the goal, and produces the goal E1 = E2.

```
Theorem mult_0_plus: \forall n \ m: nat, (0+n) \times m = n \times m.

Proof. dup.

intros n \ m.

assert (H: 0+n=n). reflexivity. rewrite \rightarrow H. reflexivity.

intros n \ m.

asserts\_rewrite \ (0+n=n).

reflexivity. Qed.
```

The tactic $cuts_rewrite$ (E1 = E2) is like $asserts_rewrite$ (E1 = E2), except that the equality E1 = E2 appears as first subgoal.

```
Theorem mult_0_plus': \forall n \ m : \mathsf{nat}, (0+n) \times m = n \times m.

Proof.

intros n \ m.

cuts\_rewrite \ (0+n=n).

reflexivity. reflexivity. Qed.
```

More generally, the tactics $asserts_rewrite$ and $cuts_rewrite$ can be provided a lemma as argument. For example, one can write $asserts_rewrite$ ($\forall \ a \ b, \ a^*(S \ b) = a \times b + a$). This formulation is useful when a and b are big terms, since there is no need to repeat their statements.

```
Theorem mult_0_plus'' : \forall u \ v \ w \ x \ y \ z: nat,

(u + v) \times (S(w \times x + y)) = z.

Proof.
```

```
intros. asserts\_rewrite \ (\forall \ a \ b, \ a*(S \ b) = a \times b+a). Admitted.
```

30.4.2 The tactic substs

The tactic *substs* is similar to **subst** except that it does not fail when the goal contains "circular equalities", such as x = f x.

```
Lemma demo_substs : \forall x \ y \ (f: \mathtt{nat} \rightarrow \mathtt{nat}), x = f \ x \rightarrow y = x \rightarrow y = f \ x. Proof.

intros. substs. assumption. Qed.
```

30.4.3 The tactic fequals

The tactic fequals is similar to f_equal except that it directly discharges all the trivial subgoals produced. Moreover, the tactic fequals features an enhanced treatment of equalities between tuples.

```
Lemma demo_fequals : \forall (a b c d e : \mathbf{nat}) (f : \mathbf{nat} \rightarrow \mathbf{nat} \rightarrow \mathbf{nat} \rightarrow \mathbf{nat} \rightarrow \mathbf{nat} \rightarrow \mathbf{nat}), a = 1 \rightarrow b = e \rightarrow e = 2 \rightarrow f a b c d = f 1 2 c 4. Proof. intros. fequals. Admitted.
```

30.4.4 The tactic $applys_eq$

The tactic $applys_eq$ is a variant of eapply that introduces equalities for subterms that do not unify. For example, assume the goal is the proposition P x y and assume we have the assumption H asserting that P x z holds. We know that we can prove y to be equal to z. So, we could call the tactic $assert_rewrite$ (y = z) and change the goal to P x z, but this would require copy-pasting the values of y and z. With the tactic $applys_eq$, we can call $applys_eq$ H 1, which proves the goal and leaves only the subgoal y = z. The value 1 given as argument to $applys_eq$ indicates that we want an equality to be introduced for the first argument of P x y counting from the right. The three following examples illustrate the behavior of a call to $applys_eq$ H 1, a call to $applys_eq$ H 2, and a call to $applys_eq$ H 1 2.

```
Axiom big\_expression\_using : nat \rightarrow nat.

Lemma demo_applys_eq_1 : \forall (P:nat \rightarrow nat \rightarrow Prop) \ x \ y \ z,

P \ x \ (big\_expression\_using \ z) \rightarrow

P \ x \ (big\_expression\_using \ y).

Proof.

introv \ H. \ dup.
```

```
assert (Eq: big\_expression\_using y = big\_expression\_using z). admit. rewrite Eq. apply H. applys\_eq H 1. admit. Qed.
```

If the mismatch was on the first argument of P instead of the second, we would have written $applys_eq\ H\ 2$. Recall that the occurences are counted from the right.

```
Lemma demo_applys_eq_2 : \forall (P:nat\rightarrownat\rightarrowProp) x y z, P (big_expression_using z) x \rightarrow P (big_expression_using y) x.

Proof.

introv\ H.\ applys_eq\ H\ 2.

Admitted.
```

When we have a mismatch on two arguments, we want to produce two equalities. To achieve this, we may call $applys_eq~H~1~2$. More generally, the tactic $applys_eq$ expects a lemma and a sequence of natural numbers as arguments.

```
Lemma demo_applys_eq_3 : \forall (P:nat\rightarrownat\rightarrowProp) x1 x2 y1 y2, P (big_{expression\_using} x2) (big_{expression\_using} y2) \rightarrow P (big_{expression\_using} x1) (big_{expression\_using} y1). Proof. introv\ H.\ applys_{eq}\ H\ 1\ 2. Admitted. End EQUALITYEXAMPLES.
```

30.5 Some convenient shorthands

This section of the tutorial introduces a few tactics that help make proof scripts shorter and more readable:

- unfolds (without argument) for unfolding the head definition,
- false for replacing the goal with False,
- gen as a shorthand for dependent generalize,
- skip for skipping a subgoal even if it contains existential variables,
- sort for re-ordering the proof context by moving moving all propositions at the bottom.

30.5.1 The tactic unfolds

Module UNFOLDSEXAMPLE.

Require Import Hoare.

The tactic *unfolds* (without any argument) unfolds the head constant of the goal. This tactic saves the need to name the constant explicitly.

```
Lemma bexp_eval_true : \forall b \ st, beval st \ b = \mathsf{true} \to (\mathsf{bassn} \ b) \ st. Proof.
intros b \ st \ Hbe. \ dup.
unfold bassn. assumption.
unfolds. assumption.
Qed.
```

Remark: contrary to the tactic hnf, which may unfold several constants, unfolds performs only a single step of unfolding.

Remark: the tactic unfolds in H can be used to unfold the head definition of the hypothesis H.

End UnfoldsExample.

30.5.2 The tactics false and tryfalse

The tactic false can be used to replace any goal with False. In short, it is a shorthand for apply $ex_falso_quodlibet$. Moreover, false proves the goal if it contains an absurd assumption, such as False or 0 = S n, or if it contains contradictory assumptions, such as x = true and x = false.

```
Lemma demo_false:
```

```
\forall n, S n = 1 \rightarrow n = 0.
```

Proof.

intros. destruct n. reflexivity. false.

Qed.

The tactic false can be given an argument: false H replace the goals with False and then applies H.

```
Lemma demo_false_arg:
```

```
(\forall n, n < 0 \rightarrow \mathsf{False}) \rightarrow (3 < 0) \rightarrow 4 < 0.
```

Proof

intros H L. false H. apply L.

Qed.

The tactic *tryfalse* is a shorthand for **try solve** [false]: it tries to find a contradiction in the goal. The tactic *tryfalse* is generally called after a case analysis.

Lemma demo_tryfalse :

```
\forall n, S \ n = 1 \rightarrow n = 0. Proof. intros. destruct n; \ tryfalse. reflexivity. Qed.
```

30.5.3 The tactic gen

The tactic gen is a shortand for generalize dependent that accepts several arguments at once. An invokation of this tactic takes the form gen x y z.

```
Module GENEXAMPLE.
  Require Import Stlc.
  Import STLC.
Lemma substitution_preserves_typing : \forall Gamma \ x \ U \ v \ t \ S,
     has_type (extend Gamma \ x \ U) \ t \ S \rightarrow
     has_type empty v \ U \rightarrow
     has_type Gamma ([x := v] t) S.
Proof.
  dup.
  intros Gamma x U v t S Htypt Htypv.
  generalize dependent S. generalize dependent Gamma.
  induction t; intros; simpl.
  admit. admit. admit. admit. admit. admit.
  introv Htypt Htypv. qen S Gamma.
  induction t; intros; simpl.
  admit. admit. admit. admit. admit. admit.
Qed.
```

End GENEXAMPLE.

30.5.4 The tactics skip, $skip_rewrite$ and $skip_goal$

Temporarily admitting a given subgoal is very useful when constructing proofs. It gives the ability to focus first on the most interesting cases of a proof. The tactic *skip* is like *admit* except that it also works when the proof includes existential variables. Recall that existential variables are those whose name starts with a question mark, e.g. ?24, and which are typically introduced by eapply.

```
Module SKIPEXAMPLE.
  Require Import Stlc.
  Import STLC.

Example astep_example1:
   (APlus (ANum 3) (AMult (ANum 3) (ANum 4))) / empty_state ==>a× (ANum 15).
Proof.
```

```
eapply multi_step. skip. eapply multi_step. skip. skip. Admitted.
```

The tactic $skip \ H$: P adds the hypothesis H: P to the context, without checking whether the proposition P is true. It is useful for exploiting a fact and postponing its proof. Note: $skip \ H$: P is simply a shorthand for assert (H:P). skip.

```
Theorem demo_skipH : True. 
Proof. 
 skip\ H: (\forall\ n\ m : nat, (0 + n) \times m = n \times m). 
 Admitted.
```

The tactic $skip_rewrite$ (E1 = E2) replaces E1 with E2 in the goal, without checking that E1 is actually equal to E2.

```
Theorem mult_0_plus: \forall n \ m: nat, (0+n) \times m = n \times m.

Proof. dup.

intros n \ m.

assert (H: 0+n=n). \ skip. \ rewrite \to H.

reflexivity.

intros n \ m.

skip\_rewrite \ (0+n=n).

reflexivity.

Qed.
```

Remark: the tactic *skip_rewrite* can in fact be given a lemma statement as argument, in the same way as *asserts_rewrite*.

The tactic $skip_goal$ adds the current goal as hypothesis. This cheat is useful to set up the structure of a proof by induction without having to worry about the induction hypothesis being applied only to smaller arguments. Using $skip_goal$, one can construct a proof in two steps: first, check that the main arguments go through without waisting time on fixing the details of the induction hypotheses; then, focus on fixing the invokations of the induction hypothesis.

```
Theorem ceval_deterministic: \forall c \ st \ st1 \ st2, c \ / \ st \ | \ st1 \rightarrow c \ / \ st \ | \ st2 \rightarrow st1 = st2.

Proof.
skip\_goal.
introv \ E1 \ E2. \ gen \ st2.
(ceval\_cases \ (induction \ E1) \ Case); introv \ E2; inverts \ E2 \ as.
Case \ "E\_Skip". \ reflexivity.
Case \ "E\_Ass".
```

```
subst n.
reflexivity.
Case "E_Seq".
intros st3 Red1 Red2.
assert (st' = st3) as EQ1.
    SCase "Proof of assertion".
eapply IH. eapply E1_1. eapply Red1.
subst st3.
eapply IH. eapply E1_2. eapply Red2.
Admitted.
End SKIPEXAMPLE.
```

30.5.5 The tactic sort

Module SORTEXAMPLES.

```
Require Import Imp.
```

The tactic *sort* reorganizes the proof context by placing all the variables at the top and all the hypotheses at the bottom, thereby making the proof context more readable.

```
Theorem ceval_deterministic: \forall c \ st \ st1 \ st2, c \ / \ st \ | \ st1 \rightarrow c \ / \ st \ | \ st2 \rightarrow st1 = st2.

Proof.

intros c \ st \ st1 \ st2 \ E1 \ E2.

generalize dependent st2.

(ceval\_cases (induction E1) Case); intros st2 \ E2; inverts \ E2.

admit. \ admit. \ sort. \ Admitted.

End SORTEXAMPLES.
```

30.6 Tactics for advanced lemma instantiation

This last section describes a mechanism for instantiating a lemma by providing some of its arguments and leaving other implicit. Variables whose instantiation is not provided are turned into existentential variables, and facts whose instantiation is not provided are turned into subgoals.

Remark: this instantion mechanism goes far beyond the abilities of the "Implicit Arguments" mechanism. The point of the instantiation mechanism described in this section is that you will no longer need to spend time figuring out how many underscore symbols you need to write.

In this section, we'll use a useful feature of Coq for decomposing conjunctions and existentials. In short, a tactic like intros or destruct can be provided with a pattern (H1 &

H2 & H3 & H4 & H5), which is a shorthand for $[H1 \ [H2 \ [H3 \ [H4 \ H5]]]]]$. For example, destruct $(H \ _ \ _ \ Htypt)$ as $[T \ [Hctx \ Hsub]]$. can be rewritten in the form destruct $(H \ _ \ _ \ Htypt)$ as (T & Hctx & Hsub).

30.6.1 Working of *lets*

When we have a lemma (or an assumption) that we want to exploit, we often need to explicitly provide arguments to this lemma, writing something like: $destruct (typing_inversion_var__ Htypt)$ as (T & Hctx & Hsub). The need to write several times the "underscore" symbol is tedious. Not only we need to figure out how many of them to write down, but it also makes the proof scripts look prettly ugly. With the tactic lets, one can simply write: lets (T & Hctx & Hsub): $typing_inversion_var\ Htypt$.

In short, this tactic *lets* allows to specialize a lemma on a bunch of variables and hypotheses. The syntax is *lets* I: E0 E1 ... EN, for building an hypothesis named I by applying the fact E0 to the arguments E1 to EN. Not all the arguments need to be provided, however the arguments that are provided need to be provided in the correct order. The tactic relies on a first-match algorithm based on types in order to figure out how the to instantiate the lemma with the arguments provided.

```
Module ExamplesLets.
```

Require Import Sub.

Qed.

```
Axiom typing_inversion_var : \forall (G:context) (x:id) (T:ty), has_type G (tvar x) T \rightarrow \exists S, G x = Some S \land subtype S T.
```

First, assume we have an assumption H with the type of the form $has_type\ G\ (tvar\ x)$ T. We can obtain the conclusion of the lemma $typing_inversion_var$ by invoking the tactics $lets\ K$: $typing_inversion_var\ H$, as shown next.

```
Lemma demo_lets_1: \forall (G:context) (x:id) (T:ty), has_type G (tvar x) T \rightarrow True.

Proof.

intros G x T H. dup.

lets K: typing\_inversion\_var H.

destruct K as (S & Eq & Sub).

admit.

lets (S & Eq & Sub): typing\_inversion\_var H.

admit.
```

Assume now that we know the values of G, x and T and we want to obtain S, and have $has_type\ G\ (tvar\ x)\ T$ be produced as a subgoal. To indicate that we want all the remaining arguments of $typing_inversion_var$ to be produced as subgoals, we use a triple-underscore

symbol ___. (We'll later introduce a shorthand tactic called *forwards* to avoid writing triple underscores.)

```
Lemma demo_lets_2 : \forall (G:context) (x:id) (T:ty), True. Proof. intros G \times T. lets (S \& Eq \& Sub): typing_inversion_var G \times T ____. Admitted.
```

Usually, there is only one context G and one type T that are going to be suitable for proving has_type G (tvar x) T, so we don't really need to bother giving G and T explicitly. It suffices to call lets (S & Eq & Sub): $typing_inversion_var$ x. The variables G and T are then instantiated using existential variables.

```
Lemma demo_lets_3 : \forall (x:id), True.

Proof.

intros x.

lets (S \& Eq \& Sub): typing\_inversion\_var x \____.

Admitted.
```

We may go even further by not giving any argument to instantiate typing_inversion_var. In this case, three unification variables are introduced.

```
Lemma demo_lets_4 : True. 
Proof. 
 lets (S \& Eq \& Sub): typing\_inversion\_var \_\_\_. 
 Admitted.
```

Note: if we provide *lets* with only the name of the lemma as argument, it simply adds this lemma in the proof context, without trying to instantiate any of its arguments.

```
Lemma demo_lets_5 : True.
Proof.

lets H: typing_inversion_var.

Admitted.
```

A last useful feature of *lets* is the double-underscore symbol, which allows skipping an argument when several arguments have the same type. In the following example, our assumption quantifies over two variables n and m, both of type nat. We would like m to be instantiated as the value 3, but without specifying a value for n. This can be achieved by writting *lets* K: H_{--} 3.

```
Lemma demo_lets_underscore :  (\forall \ n \ m, \ n \leq m \rightarrow n < m+1) \rightarrow \mathsf{True}.  Proof. intros H.  lets \ K \colon H \ 3. \qquad \mathsf{clear} \ K.   lets \ K \colon H \ \_\_ \ 3. \qquad \mathsf{clear} \ K.
```

Admitted.

Note: one can write lets: E0 E1 E2 in place of lets H: E0 E1 E2. In this case, the name H is chosen arbitrarily.

Note: the tactics *lets* accepts up to five arguments. Another syntax is available for providing more than five arguments. It consists in using a list introduced with the special symbol \gg , for example *lets H*: (\gg *E0 E1 E2 E3 E4 E5 E6 E7 E8 E9* 10).

End EXAMPLESLETS.

30.6.2 Working of applys, forwards and specializes

The tactics applys, forwards and specializes are shorthand that may be used in place of lets to perform specific tasks.

• forwards is a shorthand for instantiating all the arguments

of a lemma. More precisely, forwards H: E0 E1 E2 E3 is the same as lets H: E0 E1 E2 E3 ..., where the triple-underscore has the same meaning as explained earlier on.

• applys allows building a lemma using the advanced instantion

mode of *lets*, and then apply that lemma right away. So, *applys E0 E1 E2 E3* is the same as *lets H: E0 E1 E2 E3* followed with eapply H and then clear H.

• specializes is a shorthand for instantiating in-place

an assumption from the context with particular arguments. More precisely, specializes H E0 E1 is the same as lets H': H E0 E1 followed with clear H and rename H' into H.

Examples of use of applys appear further on. Several examples of use of forwards can be found in the tutorial chapter UseAuto.

30.6.3 Example of instantiations

Module ExamplesInstantiations.

Require Import Sub.

The following proof shows several examples where *lets* is used instead of **destruct**, as well as examples where *applys* is used instead of **apply**. The proof also contains some holes that you need to fill in as an exercise.

```
Lemma substitution_preserves_typing : \forall Gamma x U v t S, has_type (extend Gamma x U) t S \rightarrow has_type empty v U \rightarrow has_type Gamma ([x:=v]t) S. Proof with eauto.
```

```
intros Gamma x U v t S Htypt Htypv.
generalize dependent S. generalize dependent Gamma.
(t\_cases (induction t) Case); intros; simpl.
Case "tvar".
  rename i into y.
 lets\ (T\&Hctx\&Hsub): typing_inversion_var Htypt.
  unfold extend in Hctx.
  remember (beq_id x y) as e. destruct e...
  SCase "x=y".
    apply beq_id_eq in Hege. subst.
    inversion Hctx; subst. clear Hctx.
    apply context_invariance with empty...
    intros x Hcontra.
      lets [T' HT']: free_in_context S empty Hcontra...
      inversion HT'.
Case "tapp".
 admit.
Case "tabs".
  rename i into y. rename t into T1.
 lets\ (T2\&Hsub\&Htypt2): typing_inversion_abs Htypt.
 applys T_Sub (TArrow T1 T2)...
   apply T_Abs...
  remember (beq_id x y) as e. destruct e.
  SCase "x=y".
    eapply context_invariance...
    apply beq_id_eq in Heqe. subst.
    intros x Hafi. unfold extend.
    destruct (beq_id y x)...
  SCase "x<>y".
    apply IHt. eapply context_invariance...
    intros z Hafi. unfold extend.
    remember (beq_id y z) as e\theta. destruct e\theta...
    apply beq_id_eq in Heqe\theta. subst.
    rewrite \leftarrow Hege...
Case "ttrue".
  lets: typing_inversion_true Htypt...
Case "tfalse".
  lets: typing_inversion_false Htypt...
Case "tif".
  lets (Htyp1&Htyp2&Htyp3): typing_inversion_if Htypt...
Case "tunit".
```

lets: typing_inversion_unit *Htypt*...

Qed.

End EXAMPLESINSTANTIATIONS.

30.7 Summary

In this chapter we have presented a number of tactics that help make proof script more concise and more robust on change.

- *introv* and *inverts* improve naming and inversions.
- false and tryfalse help discarding absurd goals.
- unfolds automatically calls unfold on the head definition.
- gen helps setting up goals for induction.
- cases and cases_if help with case analysis.
- splits, branch and \exists to deal with n-ary constructs.
- asserts_rewrite, cuts_rewrite, substs and fequals help working with equalities.
- lets, forwards, specializes and applys provide means of very conveniently instantiating lemmas.
- applys_eq can save the need to perform manual rewriting steps before being able to apply lemma.
- *skip*, *skip_rewrite* and *skip_goal* give the flexibility to choose which subgoals to try and discharge first.

Making use of these tactics can boost one's productivity in Coq proofs.

If you are interested in using LibTactics.v in your own developments, make sure you get the lastest version from: http://www.chargueraud.org/softs/tlc/.

Chapter 31

Library UseAuto

31.1 UseAuto: Theory and Practice of Automation in Coq Proofs

In a machine-checked proof, every single detail has to be justified. This can result in huge proof scripts. Fortunately, Coq comes with a proof-search mechanism and with several decision procedures that enable the system to automatically synthesize simple pieces of proof. Automation is very powerful when set up appropriately. The purpose of this chapter is to explain the basics of working of automation.

The chapter is organized in two parts. The first part focuses on a general mechanism called "proof search." In short, proof search consists in naively trying to apply lemmas and assumptions in all possible ways. The second part describes "decision procedures", which are tactics that are very good at solving proof obligations that fall in some particular fragment of the logic of Coq.

Many of the examples used in this chapter consist of small lemmas that have been made up to illustrate particular aspects of automation. These examples are completely independent from the rest of the Software Foundations course. This chapter also contains some bigger examples which are used to explain how to use automation in realistic proofs. These examples are taken from other chapters of the course (mostly from STLC), and the proofs that we present make use of the tactics from the library LibTactics.v, which is presented in the chapter UseTactics.

Require Import LibTactics.

31.2 Basic Features of Proof Search

The idea of proof search is to replace a sequence of tactics applying lemmas and assumptions with a call to a single tactic, for example auto. This form of proof automation saves a lot of effort. It typically leads to much shorter proof scripts, and to scripts that are typically more robust to change. If one makes a little change to a definition, a proof that exploits automation

probably won't need to be modified at all. Of course, using too much automation is a bad idea. When a proof script no longer records the main arguments of a proof, it becomes difficult to fix it when it gets broken after a change in a definition. Overall, a reasonable use of automation is generally a big win, as it saves a lot of time both in building proof scripts and in subsequently maintaining those proof scripts.

31.2.1 Strength of Proof Search

We are going to study four proof-search tactics: auto, eauto, iauto and jauto. The tactics auto and eauto are builtin in Coq. The tactic iauto is a shorthand for the builtin tactic try solve [intuition eauto]. The tactic jauto is defined in the library LibTactics, and simply performs some preprocessing of the goal before calling eauto. The goal of this chapter is to explain the general principles of proof search and to give rule of thumbs for guessing which of the four tactics mentioned above is best suited for solving a given goal.

Proof search is a compromise between efficiency and expressiveness, that is, a tradeoff between how complex goals the tactic can solve and how much time the tactic requires for terminating. The tactic auto builds proofs only by using the basic tactics reflexivity, assumption, and apply. The tactic eauto can also exploit eapply. The tactic jauto extends eauto by being able to open conjunctions and existentials that occur in the context. The tactic iauto is able to deal with conjunctions, disjunctions, and negation in a quite clever way; however it is not able to open existentials from the context. Also, iauto usually becomes very slow when the goal involves several disjunctions.

Note that proof search tactics never perform any rewriting step (tactics rewrite, subst), nor any case analysis on an arbitrary data structure or predicate (tactics destruct and inversion), nor any proof by induction (tactic induction). So, proof search is really intended to automate the final steps from the various branches of a proof. It is not able to discover the overall structure of a proof.

31.2.2 Basics

The tactic auto is able to solve a goal that can be proved using a sequence of intros, apply, assumption, and reflexivity. Two examples follow. The first one shows the ability for auto to call reflexivity at any time. In fact, calling reflexivity is always the first thing that auto tries to do.

```
Lemma solving_by_reflexivity : 2 + 3 = 5.

Proof. auto. Qed.
```

The second example illustrates a proof where a sequence of two calls to apply are needed. The goal is to prove that if Q n implies P n for any n and if Q n holds for any n, then P 2 holds.

```
Lemma solving_by_apply : \forall (P \ Q : \mathbf{nat} \rightarrow \mathsf{Prop}), (\forall n, Q \ n \rightarrow P \ n) \rightarrow
```

```
 \begin{array}{ccc} (\forall \ n, \ Q \ n) \rightarrow \\ P \ 2. \end{array}
```

Proof. auto. Qed.

We can ask auto to tell us what proof it came up with, by invoking info auto in place of auto.

Proof. info auto. Qed.

The tactic auto can invoke apply but not eapply. So, auto cannot exploit lemmas whose instantiation cannot be directly deduced from the proof goal. To exploit such lemmas, one needs to invoke the tactic eauto, which is able to call eapply.

In the following example, the first hypothesis asserts that P n is true when Q m is true for some m, and the goal is to prove that Q 1 implies P 2. This implication follows direction from the hypothesis by instantiating m as the value 1. The following proof script shows that eauto successfully solves the goal, whereas auto is not able to do so.

Remark: Again, we can use info eauto to see what proof eauto comes up with.

31.2.3 Conjunctions

So far, we've seen that eauto is stronger than auto in the sense that it can deal with eapply. In the same way, we are going to see how *jauto* and *iauto* are stronger than auto and eauto in the sense that they provide better support for conjunctions.

The tactics auto and eauto can prove a goal of the form $F \wedge F'$, where F and F' are two propositions, as soon as both F and F' can be proved in the current context. An example follows.

```
Lemma solving_conj_goal : \forall (P : nat\rightarrowProp) (F : Prop), (\forall n, P n) \rightarrow F \rightarrow F \wedge P 2. Proof. auto. Qed.
```

However, when an assumption is a conjunction, auto and eauto are not able to exploit this conjunction. It can be quite surprising at first that eauto can prove very complex goals but that it fails to prove that $F \wedge F'$ implies F. The tactics *iauto* and *jauto* are able to decompose conjunctions from the context. Here is an example.

```
Lemma solving_conj_hyp : \forall (F F' : Prop), F \land F' \rightarrow F.
```

Proof. auto. eauto. jauto. Qed.

The tactic *jauto* is implemented by first calling a pre-processing tactic called *jauto_set*, and then calling eauto. So, to understand how *jauto* works, one can directly call the tactic *jauto_set*.

```
Lemma solving_conj_hyp' : \forall (F F' : Prop), F \land F' \rightarrow F.

Proof. intros. jauto\_set. eauto. Qed.
```

Next is a more involved goal that can be solved by *iauto* and *jauto*.

```
 \begin{array}{l} \mathsf{Lemma\ solving\_conj\_more}: \ \forall \ (P\ Q\ R: \mathbf{nat} {\rightarrow} \mathsf{Prop}) \ (F: \mathsf{Prop}), \\ (F \land (\forall \ n\ m, \ (Q\ m \land R\ n) \rightarrow P\ n)) \rightarrow \\ (F \rightarrow R\ 2) \rightarrow \\ Q\ 1 \rightarrow \\ P\ 2 \land F. \end{array}
```

Proof. jauto. Qed.

The strategy of *iauto* and *jauto* is to run a global analysis of the top-level conjunctions, and then call eauto. For this reason, those tactics are not good at dealing with conjunctions that occur as the conclusion of some universally quantified hypothesis. The following example illustrates a general weakness of Coq proof search mechanisms.

```
Lemma solving_conj_hyp_forall : \forall (P Q : \mathsf{nat} \rightarrow \mathsf{Prop}), (\forall n, P n \land Q n) \rightarrow P 2. Proof. auto. eauto. iauto. jauto. intros. destruct (H 2). auto. Qed.
```

This situation is slightly disappointing, since automation is able to prove the following goal, which is very similar. The only difference is that the universal quantification has been distributed over the conjunction.

```
Lemma solved_by_jauto : \forall (P Q : \mathsf{nat} \rightarrow \mathsf{Prop}) (F : \mathsf{Prop}), (\forall n, P n) \land (\forall n, Q n) \rightarrow P 2. Proof. jauto. Qed.
```

31.2.4 Disjunctions

The tactics auto and eauto can handle disjunctions that occur in the goal.

However, only *iauto* is able to automate reasoning on the disjunctions that appear in the context. For example, *iauto* can prove that $F \vee F'$ entails $F' \vee F$.

More generally, *iauto* can deal with complex combinations of conjunctions, disjunctions, and negations. Here is an example.

```
Lemma solving_tauto : \forall (F1 F2 F3 : Prop),

(\neg F1 \land F3) \lor (F2 \land \neg F3)) \rightarrow

(F2 \rightarrow F1) \rightarrow

(F2 \rightarrow F3) \rightarrow

\neg F2.
```

Proof. iauto. Qed.

However, the ability of *iauto* to automatically perform a case analysis on disjunctions comes with a downside: *iauto* may be very slow. If the context involves several hypotheses with disjunctions, *iauto* typically generates an exponential number of subgoals on which eauto is called. One major advantage of *jauto* compared with *iauto* is that it never spends time performing this kind of case analyses.

31.2.5 Existentials

The tactics eauto, iauto, and jauto can prove goals whose conclusion is an existential. For example, if the goal is $\exists x, f x$, the tactic eauto introduces an existential variable, say ?25, in place of x. The remaining goal is f ?25, and eauto tries to solve this goal, allowing itself to instantiate ?25 with any appropriate value. For example, if an assumption f 2 is available, then the variable ?25 gets instantiated with 2 and the goal is solved, as shown below.

```
Lemma solving_exists_goal : \forall (f : \mathbf{nat} \rightarrow \mathsf{Prop}), f \ 2 \rightarrow \exists \ x, f \ x.

Proof.

auto. Qed.
```

A major strength of *jauto* over the other proof search tactics is that it is able to exploit the existentially-quantified hypotheses, i.e., those of the form $\exists x, P$.

```
Lemma solving_exists_hyp : \forall (f \ g : \mathbf{nat} \rightarrow \mathsf{Prop}), (\forall \ x, f \ x \rightarrow g \ x) \rightarrow (\exists \ a, f \ a) \rightarrow (\exists \ a, g \ a).
Proof.
auto. eauto. iauto. jauto. Qed.
```

31.2.6 Negation

The tactics auto and eauto suffer from some limitations with respect to the manipulation of negations, mostly related to the fact that negation, written $\neg P$, is defined as $P \rightarrow False$ but

that the unfolding of this definition is not performed automatically. Consider the following example.

```
Lemma negation_study_1: \forall (P: \mathbf{nat} \rightarrow \mathsf{Prop}), P \ 0 \rightarrow (\forall x, \neg P \ x) \rightarrow \mathsf{False}.
Proof.
intros P \ H0 \ HX.
eauto. unfold not in *. eauto.
Qed.
```

For this reason, the tactics *iauto* and *jauto* systematically invoke unfold *not* in * as part of their pre-processing. So, they are able to solve the previous goal right away.

```
Lemma negation_study_2 : \forall (P : nat\rightarrowProp), P 0 \rightarrow (\forall x, \neg P x) \rightarrow False. Proof. jauto. Qed.
```

We will come back later on to the behavior of proof search with respect to the unfolding of definitions.

31.2.7 Equalities

Coq's proof-search feature is not good at exploiting equalities. It can do very basic operations, like exploiting reflexivity and symmetry, but that's about it. Here is a simple example that auto can solve, by first calling symmetry and then applying the hypothesis.

```
Lemma equality_by_auto : \forall (f g : \mathsf{nat} \rightarrow \mathsf{Prop}), (\forall x, f x = g x) \rightarrow g 2 = f 2. Proof. auto. Qed.
```

To automate more advanced reasoning on equalities, one should rather try to use the tactic congruence, which is presented at the end of this chapter in the "Decision Procedures" section.

31.3 How Proof Search Works

31.3.1 Search Depth

The tactic auto works as follows. It first tries to call reflexivity and assumption. If one of these calls solves the goal, the job is done. Otherwise auto tries to apply the most recently introduced assumption that can be applied to the goal without producing and error. This application produces subgoals. There are two possible cases. If the sugboals produced can be solved by a recursive call to auto, then the job is done. Otherwise, if this application produces at least one subgoal that auto cannot solve, then auto starts over by trying to apply the second most recently introduced assumption. It continues in a similar fashion until it finds a proof or until no assumption remains to be tried.

It is very important to have a clear idea of the backtracking process involved in the execution of the auto tactic; otherwise its behavior can be quite puzzling. For example, auto is not able to solve the following triviality.

```
Lemma search_depth_0:
```

```
True \( \text{True} \) \( \tex
```

The reason auto fails to solve the goal is because there are too many conjunctions. If there had been only five of them, auto would have successfully solved the proof, but six is too many. The tactic auto limits the number of lemmas and hypotheses that can be applied in a proof, so as to ensure that the proof search eventually terminates. By default, the maximal number of steps is five. One can specify a different bound, writing for example auto 6 to search for a proof involving at most six steps. For example, auto 6 would solve the previous lemma. (Similarly, one can invoke eauto 6 or intuition eauto 6.) The argument n of auto n is called the "search depth." The tactic auto is simply defined as a shorthand for auto 5.

The behavior of auto n can be summarized as follows. It first tries to solve the goal using reflexivity and assumption. If this fails, it tries to apply a hypothesis (or a lemma that has been registered in the hint database), and this application produces a number of sugoals. The tactic auto (n-1) is then called on each of those subgoals. If all the subgoals are solved, the job is completed, otherwise auto n tries to apply a different hypothesis.

During the process, auto n calls auto (n-1), which in turn might call auto (n-2), and so on. The tactic auto 0 only tries reflexivity and assumption, and does not try to apply any lemma. Overall, this means that when the maximal number of steps allowed has been exceeded, the auto tactic stops searching and backtracks to try and investigate other paths.

The following lemma admits a unique proof that involves exactly three steps. So, auto n proves this goal iff n is greater than three.

```
\begin{array}{c} \operatorname{Lemma\ search\_depth\_1}: \ \forall \ (P: \mathbf{nat} {\rightarrow} \operatorname{Prop}), \\ P\ 0 \rightarrow \\ (P\ 0 \rightarrow P\ 1) \rightarrow \\ (P\ 1 \rightarrow P\ 2) \rightarrow \\ (P\ 2). \\ \\ \operatorname{Proof.} \\ \operatorname{auto\ } 0. \quad \operatorname{auto\ } 1. \quad \operatorname{auto\ } 2. \quad \operatorname{auto\ } 3. \ \operatorname{Qed.} \end{array}
```

We can generalize the example by introducing an assumption asserting that P k is derivable from P (k-1) for all k, and keep the assumption P 0. The tactic **auto**, which is the same as **auto** 5, is able to derive P k for all values of k less than 5. For example, it can prove P 4.

```
 \begin{array}{c} \mathsf{Lemma\ search\_depth\_3}: \ \forall \ (P: \mathbf{nat} {\rightarrow} \mathsf{Prop}), \\ (P\ 0) \rightarrow \\ (\forall \ k, \ P\ (k\text{-}1) \rightarrow P\ k) \rightarrow \end{array}
```

```
\begin{array}{l} (P\ 4). \\ {\tt Proof.\ auto.\ Qed.} \\ {\tt However,\ to\ prove}\ P\ 5,\ {\tt one\ needs\ to\ call\ at\ least\ auto\ 6.} \\ {\tt Lemma\ search\_depth\_4:}\ \forall\ (P: {\tt nat}{\to}{\tt Prop}), \\ (P\ 0) \rightarrow \\ (\forall\ k,\ P\ (k{-}1) \rightarrow P\ k) \rightarrow \\ (P\ 5). \\ {\tt Proof.\ auto.\ auto\ 6.\ Qed.} \end{array}
```

Because auto looks for proofs at a limited depth, there are cases where auto can prove a goal F and can prove a goal F' but cannot prove $F \wedge F$ '. In the following example, auto can prove P 4 but it is not able to prove P 4 \wedge P 4, because the splitting of the conjunction consumes one proof step. To prove the conjunction, one needs to increase the search depth, using at least auto 6.

```
Lemma search_depth_5 : \forall (P: \mathbf{nat} \rightarrow \mathsf{Prop}), (P\ 0) \rightarrow (\forall\ k,\ P\ (k-1) \rightarrow P\ k) \rightarrow (P\ 4 \land P\ 4). Proof. auto. auto 6. Qed.
```

31.3.2 Backtracking

In the previous section, we have considered proofs where at each step there was a unique assumption that auto could apply. In general, auto can have several choices at every step. The strategy of auto consists of trying all of the possibilities (using a depth-first search exploration).

To illustrate how automation works, we are going to extend the previous example with an additional assumption asserting that P k is also derivable from P (k+1). Adding this hypothesis offers a new possibility that auto could consider at every step.

There exists a special command that one can use for tracing all the steps that proofsearch considers. To view such a trace, one should write debug eauto. (For some reason, the command debug auto does not exist, so we have to use the command debug eauto instead.)

```
Lemma working_of_auto_1 : \forall (P : \mathbf{nat} \rightarrow \mathsf{Prop}), (P\ 0) \rightarrow (\forall\ k,\ P\ (k+1) \rightarrow P\ k) \rightarrow (\forall\ k,\ P\ (k-1) \rightarrow P\ k) \rightarrow (P\ 2).

Proof. intros P\ H1\ H2\ H3. eauto. Qed.
```

The output message produced by debug eauto is as follows.

```
depth=5
depth=4 apply H3
```

```
depth=3 apply H3 depth=3 exact H1
```

The depth indicates the value of n with which eauto n is called. The tactics shown in the message indicate that the first thing that eauto has tried to do is to apply H3. The effect of applying H3 is to replace the goal P 2 with the goal P 1. Then, again, H3 has been applied, changing the goal P 1 into P 0. At that point, the goal was exactly the hypothesis H1.

It seems that eauto was quite lucky there, as it never even tried to use the hypothesis H2 at any time. The reason is that auto always tries to use the most recently introduced hypothesis first, and H3 is a more recent hypothesis than H2 in the goal. So, let's permute the hypotheses H2 and H3 and see what happens.

```
Lemma working_of_auto_2 : \forall (P : \mathbf{nat} \rightarrow \mathbf{Prop}), (P\ 0) \rightarrow (\forall\ k,\ P\ (k-1) \rightarrow P\ k) \rightarrow (\forall\ k,\ P\ (k+1) \rightarrow P\ k) \rightarrow (P\ 2). Proof. intros P\ H1\ H3\ H2. eauto. Qed.
```

This time, the output message suggests that the proof search investigates many possibilities. Replacing debug eauto with info eauto, we observe that the proof that eauto comes up with is actually not the simplest one. apply H2; apply H3; apply H3; apply H3; exact H1 This proof goes through the proof obligation P 3, even though it is not any useful. The

|5||4||3||2||1||0| -- below, tabulation indicates the depth

following tree drawing describes all the goals that automation has been through.

```
[P 2]
-> [P 3]
   -> [P 4]
      -> [P 5]
          -> [P 6]
             -> [P 7]
             -> [P 5]
          -> [P 4]
             -> [P 5]
             -> [P 3]
       --> [P 3]
          -> [P 4]
             -> [P 5]
             -> [P 3]
          -> [P 2]
             -> [P 3]
             -> [P 1]
   -> [P 2]
```

```
-> [P 3]
-> [P 4]
-> [P 5]
-> [P 3]
-> [P 3]
-> [P 3]
-> [P 1]
-> [P 1]
-> [P 2]
-> [P 3]
-> [P 1]
-> [P 0]
-> !! Done !!
```

The first few lines read as follows. To prove P 2, eauto 5 has first tried to apply H2, producing the subgoal P 3. To solve it, eauto 4 has tried again to apply H2, producing the goal P 4. Similarly, the search goes through P 5, P 6 and P 7. When reaching P 7, the tactic eauto 0 is called but as it is not allowed to try and apply any lemma, it fails. So, we come back to the goal P 6, and try this time to apply hypothesis H3, producing the subgoal P 5. Here again, eauto 0 fails to solve this goal.

The process goes on and on, until backtracking to P 3 and trying to apply H2 three times in a row, going through P 2 and P 1 and P 0. This search tree explains why eauto came up with a proof starting with apply H2.

31.3.3 Adding Hints

By default, auto (and eauto) only tries to apply the hypotheses that appear in the proof context. There are two possibilities for telling auto to exploit a lemma that have been proved previously: either adding the lemma as an assumption just before calling auto, or adding the lemma as a hint, so that it can be used by every calls to auto.

The first possibility is useful to have auto exploit a lemma that only serves at this particular point. To add the lemma as hypothesis, one can type generalize mylemma; intros, or simply lets: mylemma (the latter requires LibTactics.v).

The second possibility is useful for lemmas that need to be exploited several times. The syntax for adding a lemma as a hint is Hint Resolve mylemma. For example, the lemma asserting than any number is less than or equal to itself, $\forall x, x \leq x$, called Le.le_reft in the Coq standard library, can be added as a hint as follows.

Hint Resolve Le.le_refl.

A convenient shorthand for adding all the constructors of an inductive datatype as hints is the command Hint Constructors *mydatatype*.

Warning: some lemmas, such as transitivity results, should not be added as hints as they would very badly affect the performance of proof search. The description of this problem and the presentation of a general work-around for transitivity lemmas appear further on.

31.3.4 Integration of Automation in Tactics

The definition of *auto_star*, which determines the meaning of the star symbol, can be modified whenever needed. Simply write: Ltac auto_star ::= a_new_definition.]] Observe the use of ::= instead of :=, which indicates that the tactic is being rebound to a new definition. So, the default definition is as follows.

Ltac $auto_star ::= try solve [auto | jauto].$

Nearly all standard Coq tactics and all the tactics from "LibTactics" can be called with a star symbol. For example, one can invoke $\mathtt{subst} \times$, $\mathtt{destruct} \times H$, $inverts \times H$, $lets \times I$: H x, $specializes \times H$ x, and so on... There are two notable exceptions. The tactic $\mathtt{auto} \times \mathtt{is}$ just another name for the tactic $auto_star$. And the tactic $\mathtt{apply} \times H$ calls $\mathtt{eapply} H$ (or the more powerful applys H if needed), and then calls $auto_star$. Note that there is no $\mathtt{eapply} \times H$ tactic, use $\mathtt{apply} \times H$ instead.

In large developments, it can be convenient to use two degrees of automation. Typically, one would use a fast tactic, like auto, and a slower but more powerful tactic, like jauto. To allow for a smooth coexistence of the two form of automation, LibTactics.v also defines a "tilde" version of tactics, like apply¬H, destruct¬H, subst¬, auto¬ and so on. The meaning of the tilde symbol is described by the $auto_tilde$ tactic, whose default implementation is auto.

Ltac $auto_tilde ::= auto.$

In the examples that follow, only *auto_star* is needed.

31.4 Examples of Use of Automation

Let's see how to use proof search in practice on the main theorems of the "Software Foundations" course, proving in particular results such as determinism, preservation and progress.

31.4.1 Determinism

Module DeterministicImp.

Require Import Imp.

Recall the original proof of the determinism lemma for the IMP language, shown below.

Theorem ceval_deterministic: $\forall c \ st \ st1 \ st2$,

```
c / st \mid \mid st1 \rightarrow
  c / st \mid \mid st2 \rightarrow
  st1 = st2.
Proof.
  intros c st st1 st2 E1 E2.
  generalize dependent st2.
  (ceval\_cases (induction E1) Case); intros st2 E2; inversion E2; subst.
  Case "E_Skip". reflexivity.
  Case "E_Ass". reflexivity.
  Case "E_Seq".
    assert (st' = st'0) as EQ1.
       SCase "Proof of assertion". apply IHE1_1; assumption.
    subst st'\theta.
    apply IHE1_{-}2. assumption.
  Case "E_IfTrue".
    SCase "b1 evaluates to true".
       apply IHE1. assumption.
    SCase "b1 evaluates to false (contradiction)".
      rewrite H in H5. inversion H5.
  Case "E_IfFalse".
    SCase "b1 evaluates to true (contradiction)".
      rewrite H in H5. inversion H5.
    SCase "b1 evaluates to false".
       apply IHE1. assumption.
  Case "E_WhileEnd".
    SCase "b1 evaluates to true".
      reflexivity.
    SCase "b1 evaluates to false (contradiction)".
      rewrite H in H2. inversion H2.
  Case "E_WhileLoop".
    SCase "b1 evaluates to true (contradiction)".
      rewrite H in H4. inversion H4.
    SCase "b1 evaluates to false".
       assert (st' = st'\theta) as EQ1.
         SSCase "Proof of assertion". apply IHE1_1; assumption.
       subst st'\theta.
       apply IHE1_2. assumption.
Qed.
   Exercise: rewrite this proof using auto whenever possible. (The solution uses auto 9
times.)
Theorem ceval_deterministic': \forall c \ st \ st1 \ st2,
  c / st \mid \mid st1 \rightarrow
```

```
c / st \mid \mid st2 \rightarrow st1 = st2.

Proof.

admit.

Qed.
```

In fact, using automation is not just a matter of calling **auto** in place of one or two other tactics. Using automation is about rethinking the organization of sequences of tactics so as to minimize the effort involved in writing and maintaining the proof. This process is eased by the use of the tactics from *LibTactics.v.* So, before trying to optimize the way automation is used, let's first rewrite the proof of determinism:

- use $introv\ H$ instead of intros $x\ H$,
- use gen x instead of generalize dependent x,
- use *inverts H* instead of inversion H; subst,
- use tryfalse to handle contradictions, and get rid of the cases where $beval\ st\ b1 = true$ and $beval\ st\ b1 = false$ both appear in the context,
- stop using *ceval_cases* to label subcases.

```
Theorem ceval_deterministic'': \forall \ c \ st \ st1 \ st2, c \ / \ st \ | \ | \ st1 \rightarrow c \ / \ st \ | \ | \ st2 \rightarrow st1 = st2.
Proof.

introv \ E1 \ E2. \ gen \ st2.
induction \ E1; \ intros; \ inverts \ E2; \ tryfalse.
auto.
auto.
auto.
ausert (st' = st'0). auto. subst. auto.
auto.
auto.
auto.
Qed.
```

To obtain a nice clean proof script, we have to remove the calls assert $(st' = st'\theta)$. Such a tactic invokation is not nice because it refers to some variables whose name has been automatically generated. This kind of tactics tend to be very brittle. The tactic assert $(st' = st'\theta)$ is used to assert the conclusion that we want to derive from the induction hypothesis. So, rather than stating this conclusion explicitly, we are going to ask Coq to instantiate the induction hypothesis, using automation to figure out how to instantiate it.

The tactic forwards, described in LibTactics.v precisely helps with instantiating a fact. So, let's see how it works out on our example.

```
Theorem ceval_deterministic''': \forall c \ st \ st1 \ st2,
  c / st \mid \mid st1 \rightarrow
  c / st \mid \mid st2 \rightarrow
  st1 = st2.
Proof.
  introv E1 E2. gen st2.
  induction E1; intros; inverts E2; tryfalse.
  auto. auto.
  dup 4.
  assert (st' = st'0). apply IHE1_1. apply H1.
  forwards: IHE1_1. apply H1.
    skip.
  forwards: IHE1_1. eauto.
    skip.
  forwards*: IHE1_1.
    skip.
Admitted.
```

To polish the proof script, it remains to factorize the calls to auto, using the star symbol. The proof of determinism can then be rewritten in only four lines, including no more than 10 tactics.

```
Theorem ceval_deterministic''': \forall \ c \ st \ st1 \ st2,
c \ / \ st \ | \ | \ st1 \rightarrow
c \ / \ st \ | \ | \ st2 \rightarrow
st1 = st2.

Proof.

introv \ E1 \ E2. \ gen \ st2.
induction \ E1; \ intros; \ inverts \times \ E2; \ tryfalse.
forwards^*: \ IHE1\_1. \ subst \times.
forwards^*: \ IHE1\_1. \ subst \times.
Qed.
```

31.4.2 Preservation for STLC

End DeterministicImp.

```
 \begin{tabular}{ll} {\tt Module\ PRESERVATIONPROGRESSSTLC.}\\ {\tt Require\ Import\ Stlc.}\\ {\tt Import\ } STLC. \end{tabular}
```

Consider the proof of perservation of STLC, shown below. This proof already uses eauto through the triple-dot mechanism.

```
Theorem preservation : \forall t t' T,
  has_type empty t T \rightarrow
  t ==> t' \rightarrow
  has_type empty t' T.
Proof with eauto.
  remember (@empty ty) as Gamma.
  intros t t T HT. generalize dependent t T.
  (has\_type\_cases (induction HT) Case); intros t' HE; subst Gamma.
  Case "T_Var".
    inversion HE.
  Case "T_Abs".
    inversion HE.
  Case "T_App".
    inversion HE; subst...
    SCase "ST_AppAbs".
      apply substitution_preserves_typing with T11...
      inversion HT1...
  Case "T_True".
    inversion HE.
  Case "T_False".
    inversion HE.
  Case "T_If".
    inversion HE; subst...
Qed.
```

Exercise: rewrite this proof using tactics from LibTactics and calling automation using the star symbol rather than the triple-dot notation. More precisely, make use of the tactics $inverts \times$ and $applys \times$ to call $\mathtt{auto} \times$ after a call to inverts or to applys. The solution is three lines long.

```
Theorem preservation': \forall \ t \ t' T, \mathbf{has\_type} empty t \ T \rightarrow t ==> t' \rightarrow \mathbf{has\_type} empty t' T. Proof. admit. Qed.
```

31.4.3 Progress for STLC

Consider the proof of the progress theorem.

Theorem progress: $\forall t T$,

```
has_type empty t T \rightarrow
  value t \vee \exists t', t ==> t'.
Proof with eauto.
  intros t T Ht.
  remember (@empty ty) as Gamma.
  (has_type_cases (induction Ht) Case); subst Gamma...
  Case "T_Var".
     inversion H.
  Case "T_App".
    right. destruct IHHt1...
     SCase "t1 is a value".
       destruct IHHt2...
       SSCase "t2 is a value".
         inversion H; subst; try solve by inversion.
         \exists ([x\theta := t2]t)...
       SSCase "t2 steps".
        destruct H0 as [t2' Hstp]. \exists (tapp t1 \ t2')...
     SCase "t1 steps".
       destruct H as [t1] Hstp. \exists (tapp \ t1] t2)...
  Case "T_If".
     right. destruct IHHt1...
    destruct t1; try solve by inversion...
     inversion H. \exists (tif x0 \ t2 \ t3)...
Qed.
   Exercise: optimize the above proof. Hint: make use of destruct \times and inverts \times. The
solution consists of 10 short lines.
Theorem progress': \forall t T,
  has_type empty t T \rightarrow
  value t \vee \exists t', t \Longrightarrow t'.
Proof.
   admit.
Qed.
End PreservationProgressStlc.
```

31.4.4 BigStep and SmallStep

Module SEMANTICS.

Require Import Smallstep.

Consider the proof relating a small-step reduction judgment to a big-step reduction judgment.

Theorem multistep__eval : $\forall t v$,

```
normal_form_of t \ v \to \exists \ n, \ v = \mathsf{C} \ n \land t \mid \mid n.

Proof.

intros t \ v \ Hnorm.

unfold normal_form_of in Hnorm.

inversion Hnorm as [Hs \ Hnf]; clear Hnorm.

rewrite nf_same_as_value in Hnf. inversion Hnf. clear Hnf.

\exists \ n. split. reflexivity.

multi\_cases (induction Hs) Case; subst.

Case "multi\_refl".

apply E_Const.

Case "multi_step".

eapply step\_\_eval. eassumption. apply IHHs. reflexivity.

Qed.
```

Our goal is to optimize the above proof. It is generally easier to isolate inductions into separate lemmas. So, we are going to first prove an intermediate result that consists of the judgment over which the induction is being performed.

Exercise: prove the following result, using tactics *introv*, **induction** and **subst**, and apply×. The solution is 3 lines long.

```
Theorem multistep_eval_ind : \forall \ t \ v, t ==>* \ v \rightarrow \forall \ n, \ \mathsf{C} \ n = v \rightarrow t \ | \ | \ n. Proof. admit. Qed.
```

Exercise: using the lemma above, simplify the proof of the result $multistep_eval$. You should use the tactics introv, inverts, $split \times$ and $apply \times$. The solution is 2 lines long.

```
Theorem multistep__eval': \forall \ t \ v, normal_form_of t \ v \to \exists \ n, v = C \ n \land t \mid \mid \ n. Proof. admit. Qed.
```

If we try to combine the two proofs into a single one, we will likely fail, because of a limitation of the induction tactic. Indeed, this tactic looses information when applied to a predicate whose arguments are not reduced to variables, such as $t ==>^* (C n)$. You will thus need to use the more powerful tactic called dependent induction. This tactic is available only after importing the *Program* library, as shown below.

```
Require Import Program.
```

Exercise: prove the lemma *multistep_eval* without invoking the lemma *multistep_eval_ind*, that is, by inlining the proof by induction involved in *multistep_eval_ind*, using the tactic dependent induction instead of induction. The solution is 5 lines long.

```
Theorem multistep__eval'' : \forall t v,
```

```
normal_form_of t v \to \exists n, v = C n \land t \mid \mid n. Proof. admit. Qed. End SEMANTICS.
```

31.4.5 Preservation for STLCRef

Module PreservationProgressReferences.

```
Require Import References.

Import STLCRef.

Hint Resolve store_weakening extends_refl.
```

The proof of preservation for *STLCRef* can be found in chapter *References*. It contains 58 lines (not counting the labelling of cases). The optimized proof script is more than twice shorter. The following material explains how to build the optimized proof script. The resulting optimized proof script for the preservation theorem appears afterwards.

```
Theorem preservation : \forall ST \ t \ t' \ T \ st \ st',
  has_type empty ST\ t\ T \rightarrow
  store\_well\_typed ST st \rightarrow
  t / st ==> t' / st' \rightarrow
  \exists ST',

Qed.
```

Let's come back to the proof case that was hard to optimize. The difficulty comes from the statement of nth_eq_snoc , which takes the form nth (length l) (snoc l x) d=x. This lemma is hard to exploit because its first argument, length l, mentions a list l that has to be exactly the same as the l occurring in $snoc\ l$ x. In practice, the first argument is often a natural number n that is provably equal to length l yet that is not syntactically equal to length l. There is a simple fix for making nth_eq_snoc easy to apply: introduce the intermediate variable n explicitly, so that the goal becomes $nth\ n$ ($snoc\ l\ x$) d=x, with a premise asserting $n=length\ l$.

```
Lemma nth_eq_snoc': \forall (A: Type) (l: list A) (x d: A) (n: nat), n = length \ l \rightarrow nth \ n \ (snoc \ l \ x) \ d = x.
Proof. intros. subst. apply nth_eq_snoc. Qed.
```

The proof case for ref from the preservation theorem then becomes much easier to prove, because rewrite nth_eq_snoc ' now succeeds.

```
Lemma preservation_ref : \forall (st:store) (ST : store_ty) T1,
```

```
length ST = length st \rightarrow
  TRef T1 = TRef (store_Tlookup (length st) (snoc ST T1)).
Proof.

End PreservationProgressReferences.

31.4.7 Subtyping

Module SubtypingInversion.

Require Import Sub.

Consider the inversion lemma for typing judgment of abstractions in a type system with subtyping.

Lemma abs_arrow : $\forall x S1 \ s2 \ T1 \ T2$,

```
has_type empty (tabs x S1 s2) (TArrow T1 T2) → subtype T1 S1 
 \land has_type (extend empty x S1) s2 T2. Proof with eauto. intros x S1 s2 T1 T2 Hty. apply typing_inversion_abs in Hty. destruct Hty as [S2 [Hsub Hty]]. apply sub\_inversion\_arrow in Hsub. destruct Hsub as [U1 [U2 [Heq [Hsub1 Hsub2]]]]]. inversion <math>Heq; subst... Qed.
```

Exercise: optimize the proof script, using introv, lets and $inverts \times$. In particular, you will find it useful to replace the pattern apply K in H. destruct H as I with lets I: K H. The solution is 4 lines.

```
Lemma abs_arrow': \forall \ x \ S1 \ s2 \ T1 \ T2, has_type empty (tabs x \ S1 \ s2) (TArrow T1 \ T2) \rightarrow subtype T1 \ S1
\land has_type (extend empty x \ S1) s2 \ T2.

Proof.

admit.
Qed.
```

The lemma substitution_preserves_typing has already been used to illustrate the working of lets and applys in chapter UseTactics. Optimize further this proof using automation (with the star symbol), and using the tactic cases_if'. The solution is 33 lines, including the Case instructions (21 lines without them).

```
Lemma substitution_preserves_typing : \forall \ Gamma \ x \ U \ v \ t \ S, has_type (extend Gamma \ x \ U) \ t \ S \rightarrow has_type empty v \ U \rightarrow has_type Gamma \ ([x:=v]t) \ S.

Proof. admit.
Qed.
```

End SubtypingInversion.

31.5 Advanced Topics in Proof Search

31.5.1 Stating Lemmas in the Right Way

Due to its depth-first strategy, eauto can get exponentially slower as the depth search increases, even when a short proof exists. In general, to make proof search run reasonably

fast, one should avoid using a depth search greater than 5 or 6. Moreover, one should try to minimize the number of applicable lemmas, and usually put first the hypotheses whose proof usefully instantiates the existential variables.

In fact, the ability for eauto to solve certain goals actually depends on the order in which the hypotheses are stated. This point is illustrated through the following example, in which P is a predicate on natural numbers. This predicate is such that P n holds for any n as soon as P m holds for at least one m different from zero. The goal is to prove that P 2 implies P 1. When the hypothesis about P is stated in the form \forall n m, P $m \rightarrow m \neq 0 \rightarrow P$ n, then eauto works. However, with \forall n m, m \neq $0 \rightarrow P$ m \rightarrow P n, the tactic eauto fails.

```
Lemma order_matters_1 : \forall (P: \mathbf{nat} \rightarrow \mathsf{Prop}), (\forall n \ m, P \ m \rightarrow m \neq 0 \rightarrow P \ n) \rightarrow P \ 2 \rightarrow P \ 1. Proof.
eauto. Qed.

Lemma order_matters_2 : \forall (P: \mathbf{nat} \rightarrow \mathsf{Prop}), (\forall n \ m, m \neq 0 \rightarrow P \ m \rightarrow P \ n) \rightarrow P \ 5 \rightarrow P \ 1. Proof.
eauto.
intros P \ H \ K.
eapply H.
eauto.
Admitted.
```

It is very important to understand that the hypothesis $\forall n \ m, \ P \ m \rightarrow m \neq 0 \rightarrow P \ n$ is eauto-friendly, whereas $\forall n \ m, \ m \neq 0 \rightarrow P \ m \rightarrow P \ n$ really isn't. Guessing a value of m for which $P \ m$ holds and then checking that $m \neq 0$ holds works well because there are few values of m for which $P \ m$ holds. So, it is likely that eauto comes up with the right one. On the other hand, guessing a value of m for which $m \neq 0$ and then checking that $P \ m$ holds does not work well, because there are many values of m that satisfy $m \neq 0$ but not $P \ m$.

31.5.2 Unfolding of Definitions During Proof-Search

The use of intermediate definitions is generally encouraged in a formal development as it usually leads to more concise and more readable statements. Yet, definitions can make it a little harder to automate proofs. The problem is that it is not obvious for a proof search mechanism to know when definitions need to be unfolded. Note that a naive strategy that consists in unfolding all definitions before calling proof search does not scale up to large proofs, so we avoid it. This section introduces a few techniques for avoiding to manually unfold definitions before calling proof search.

To illustrate the treatment of definitions, let P be an abstract predicate on natural numbers, and let myFact be a definition denoting the proposition P x holds for any x less than or equal to 3.

```
Axiom P: \mathbf{nat} \to \mathsf{Prop}.
```

```
Definition myFact := \forall x, x \leq 3 \rightarrow P x.
```

Proving that myFact under the assumption that P x holds for any x should be trivial. Yet, auto fails to prove it unless we unfold the definition of myFact explicitly.

```
Lemma demo_hint_unfold_goal_1:
```

```
(\forall x, P x) \rightarrow \mathsf{myFact}.
```

Proof.

```
auto. unfold myFact. auto. Qed.
```

To automate the unfolding of definitions that appear as proof obligation, one can use the command Hint Unfold myFact to tell Coq that it should always try to unfold myFact when myFact appears in the goal.

Hint Unfold myFact.

This time, automation is able to see through the definition of myFact.

Lemma demo_hint_unfold_goal_2:

```
(\forall x, P x) \rightarrow \mathsf{myFact}.
```

Proof. auto. Qed.

However, the Hint Unfold mechanism only works for unfolding definitions that appear in the goal. In general, proof search does not unfold definitions from the context. For example, assume we want to prove that P 3 holds under the assumption that $True \rightarrow myFact$.

```
Lemma demo_hint_unfold_context_1:
```

```
(\text{True} \rightarrow \text{myFact}) \rightarrow P 3.
```

Proof.

intros.

```
auto. unfold myFact in *. auto. Qed.
```

There is actually one exception to the previous rule: a constant occurring in an hypothesis is automatically unfolded if the hypothesis can be directly applied to the current goal. For example, auto can prove $myFact \rightarrow P$ 3, as illustrated below.

```
Lemma demo_hint_unfold_context_2:
```

```
myFact \rightarrow P 3.
```

Proof. auto. Qed.

31.5.3 Automation for Proving Absurd Goals

In this section, we'll see that lemmas concluding on a negation are generally not useful as hints, and that lemmas whose conclusion is *False* can be useful hints but having too many of them makes proof search inefficient. We'll also see a practical work-around to the efficiency issue.

Consider the following lemma, which asserts that a number less than or equal to 3 is not greater than 3.

Parameter $le_not_gt: \forall x$,

```
(x \le 3) \rightarrow \neg (x > 3).
```

Equivalently, one could state that a number greater than three is not less than or equal to 3.

```
Parameter gt\_not\_le : \forall x,
(x > 3) \rightarrow \neg (x \le 3).
```

In fact, both statements are equivalent to a third one stating that $x \leq 3$ and x > 3 are contradictory, in the sense that they imply False.

```
Parameter le\_gt\_false : \forall x,
(x \le 3) \to (x > 3) \to False.
```

The following investigation aim at figuring out which of the three statments is the most convenient with respect to proof automation. The following material is enclosed inside a **Section**, so as to restrict the scope of the hints that we are adding. In other words, after the end of the section, the hints added within the section will no longer be active.

Section DemoAbsurd1.

Let's try to add the first lemma, le_not_gt , as hint, and see whether we can prove that the proposition $\exists x, x \leq 3 \land x > 3$ is absurd.

```
Hint Resolve le_not_gt.
```

```
Lemma demo_auto_absurd_1: (\exists \ x \text{, } x \leq 3 \land x > 3) \rightarrow \textbf{False}. Proof. \texttt{intros. } \textit{jauto\_set}. \texttt{ eauto. } \texttt{ eapply } \textit{le\_not\_gt}. \texttt{ eauto. } \texttt{ eauto.} Qed.
```

The lemma gt_not_le is symmetric to le_not_gt , so it will not be any better. The third lemma, le_gt_false , is a more useful hint, because it concludes on False, so proof search will try to apply it when the current goal is False.

```
Hint Resolve le_gt_false.
```

```
Lemma demo_auto_absurd_2: (\exists \ x, \ x \leq 3 \land x > 3) \rightarrow \textbf{False}. Proof. dup. intros. jauto\_set. eauto. jauto. Qed.
```

In summary, a lemma of the form $H1 \to H2 \to False$ is a much more effective hint than $H1 \to \neg H2$, even though the two statments are equivalent up to the definition of the negation symbol \neg .

That said, one should be careful with adding lemmas whose conclusion is *False* as hint. The reason is that whenever reaching the goal *False*, the proof search mechanism will po-

tentially try to apply all the hints whose conclusion is *False* before applying the appropriate one.

End DemoAbsurd1.

Adding lemmas whose conclusion is False as hint can be, locally, a very effective solution. However, this approach does not scale up for global hints. For most practical applications, it is reasonable to give the name of the lemmas to be exploited for deriving a contradiction. The tactic $false\ H$, provided by LibTactics serves that purpose: $false\ H$ replaces the goal with False and calls eapply H. Its behavior is described next. Observe that any of the three statements le_not_gt , gt_not_le or le_gt_false can be used.

```
Lemma demo_false : \forall x, (x \leq 3) \rightarrow (x > 3) \rightarrow 4 = 5. Proof.

intros. dup \ 4.

false. eapply le\_gt\_false.

auto. skip.

false. eapply le\_gt\_false.

eauto. eauto.

false \ le\_gt\_false. eauto. eauto.

false \ le\_not\_gt. eauto. eauto.

Qed.
```

In the above example, false le_gt_false ; eauto proves the goal, but false le_gt_false ; auto does not, because auto does not correctly instantiate the existential variable. Note that $false \times le_gt_false$ would not work either, because the star symbol tries to call auto first. So, there are two possibilities for completing the proof: either call $false\ le_gt_false$; eauto, or call $false \times (le_gt_false\ 3)$.

31.5.4 Automation for Transitivity Lemmas

Some lemmas should never be added as hints, because they would very badly slow down proof search. The typical example is that of transitivity results. This section describes the problem and presents a general workaround.

Consider a subtyping relation, written $subtype\ S\ T$, that relates two object S and T of type typ. Assume that this relation has been proved reflexive and transitive. The corresponding lemmas are named $subtype_refl$ and $subtype_trans$.

```
Parameter typ: Type.

Parameter subtype: typ \rightarrow typ \rightarrow Prop.

Parameter subtype\_refl: \forall T,
 subtype \ T \ T.

Parameter subtype\_trans: \forall S \ T \ U,
```

```
subtype S \ T \to \text{subtype} \ T \ U \to \text{subtype} \ S \ U.
```

Adding reflexivity as hint is generally a good idea, so let's add reflexivity of subtyping as hint.

Hint Resolve subtype_refl.

Adding transitivity as hint is generally a bad idea. To understand why, let's add it as hint and see what happens. Because we cannot remove hints once we've added them, we are going to open a "Section," so as to restrict the scope of the transitivity hint to that section.

Section HintsTransitivity.

Hint Resolve subtype_trans.

Now, consider the goal $\forall S T$, subtype S T, which clearly has no hope of being solved. Let's call eauto on this goal.

```
Lemma transitivity_bad_hint_1: \forall \ S \ T, subtype S \ T.

Proof.
intros. eauto. Admitted.
```

Note that after closing the section, the hint *subtype_trans* is no longer active.

End HintsTransitivity.

In the previous example, the proof search has spent a lot of time trying to apply transitivity and reflexivity in every possible way. Its process can be summarized as follows. The first goal is $subtype\ S\ T$. Since reflexivity does not apply, eauto invokes transitivity, which produces two subgoals, $subtype\ S\ ?X$ and $subtype\ ?X\ T$. Solving the first subgoal, $subtype\ S\ ?X$, is straightforward, it suffices to apply reflexivity. This unifies ?X with S. So, the second sugoal, $subtype\ ?X\ T$, becomes $subtype\ S\ T$, which is exactly what we started from...

The problem with the transitivity lemma is that it is applicable to any goal concluding on a subtyping relation. Because of this, eauto keeps trying to apply it even though it most often doesn't help to solve the goal. So, one should never add a transitivity lemma as a hint for proof search.

There is a general workaround for having automation to exploit transitivity lemmas without giving up on efficiency. This workaround relies on a powerful mechanism called "external hint." This mechanism allows to manually describe the condition under which a particular lemma should be tried out during proof search.

For the case of transitivity of subtyping, we are going to tell Coq to try and apply the transitivity lemma on a goal of the form $subtype\ S\ U$ only when the proof context already contains an assumption either of the form $subtype\ S\ T$ or of the form $subtype\ T\ U$. In other words, we only apply the transitivity lemma when there is some evidence that this application might help. To set up this "external hint," one has to write the following.

```
Hint Extern 1 (subtype ?S ?U) \Rightarrow match goal with \mid H: subtype \ S ?T \vdash \_ \Rightarrow apply (@subtype\_trans \ S \ T \ U)
```

```
\mid H: subtype ?T \ U \vdash \_ \Rightarrow apply (@subtype\_trans \ S \ T \ U) end.
```

This hint declaration can be understood as follows.

- "Hint Extern" introduces the hint.
- The number "1" corresponds to a priority for proof search. It doesn't matter so much what priority is used in practice.
- The pattern subtype ?S ?U describes the kind of goal on which the pattern should apply. The question marks are used to indicate that the variables ?S and ?U should be bound to some value in the rest of the hint description.
- The construction match goal with ... end tries to recognize patterns in the goal, or in the proof context, or both.
- The first pattern is H: $subtype\ S\ ?T \vdash _$. It indices that the context should contain an hypothesis H of type $subtype\ S\ ?T$, where S has to be the same as in the goal, and where ?T can have any value.
- The symbol \vdash at the end of H: subtype S ? T \vdash indicates that we do not impose further condition on how the proof obligation has to look like.
- The branch \Rightarrow apply (@subtype_trans S T U) that follows indicates that if the goal has the form subtype S U and if there exists an hypothesis of the form subtype S T, then we should try and apply transitivity lemma instantiated on the arguments S, T and U. (Note: the symbol @ in front of subtype_trans is only actually needed when the "Implicit Arguments" feature is activated.)
- The other branch, which corresponds to an hypothesis of the form H: subtype ? T U is symmetrical.

Note: the same external hint can be reused for any other transitive relation, simply by renaming *subtype* into the name of that relation.

Let us see an example illustrating how the hint works.

```
Lemma transitivity_workaround_1: \forall T1 \ T2 \ T3 \ T4, subtype T1 \ T2 \rightarrow subtype T2 \ T3 \rightarrow subtype T3 \ T4 \rightarrow subtype T1 \ T4. Proof. intros. eauto. Qed.
```

We may also check that the new external hint does not suffer from the complexity blow up.

```
Lemma transitivity_workaround_2 : \forall S \ T, subtype S \ T.

Proof.
intros. eauto. Admitted.
```

31.6 Decision Procedures

A decision procedure is able to solve proof obligations whose statement admits a particular form. This section describes three useful decision procedures. The tactic omega handles goals involving arithmetic and inequalities, but not general multiplications. The tactic ring handles goals involving arithmetic, including multiplications, but does not support inequalities. The tactic congruence is able to prove equalities and inequalities by exploiting equalities available in the proof context.

31.6.1 Omega

The tactic omega supports natural numbers (type nat) as well as integers (type Z, available by including the module ZArith). It supports addition, substraction, equalities and inequalities. Before using omega, one needs to import the module Omega, as follows.

```
Require Import Omega.
```

Here is an example. Let x and y be two natural numbers (they cannot be negative). Assume y is less than 4, assume x+x+1 is less than y, and assume x is not zero. Then, it must be the case that x is equal to one.

```
Lemma omega_demo_1: \forall (x \ y : \mathbf{nat}), (y \le 4) \to (x + x + 1 \le y) \to (x \ne 0) \to (x = 1). Proof. intros. omega. Qed.
```

Another example: if z is the mean of x and y, and if the difference between x and y is at most 4, then the difference between x and z is at most 2.

```
Lemma omega_demo_2 : \forall (x \ y \ z : \mathbf{nat}), (x + y = z + z) \rightarrow (x - y \le 4) \rightarrow (x - z \le 2). Proof. intros. omega. Qed.
```

One can proof False using omega if the mathematical facts from the context are contradictory. In the following example, the constraints on the values x and y cannot be all satisfied in the same time.

```
Lemma omega_demo_3 : \forall (x y : nat), (x + 5 \leq y) \rightarrow (y - x < 3) \rightarrow False. Proof. intros. omega. Qed.
```

Note: omega can prove a goal by contradiction only if its conclusion is reduced False. The tactic omega always fails when the conclusion is an arbitrary proposition P, even though False implies any proposition P (by $ex_falso_quodlibet$).

```
Lemma omega_demo_4 : \forall (x \ y : \mathbf{nat}) (P : \mathsf{Prop}), (x + 5 \le y) \to (y - x \le 3) \to P. Proof. intros. false. omega.
```

31.6.2 Ring

Compared with omega, the tactic ring adds support for multiplications, however it gives up the ability to reason on inequations. Moreover, it supports only integers (type Z) and not natural numbers (type nat). Here is an example showing how to use ring.

```
Module RINGDEMO.
Require Import ZArith.
Open Scope Z_scope.

Lemma ring_demo: \forall (x \ y \ z : \mathbf{Z}), \\ x \times (y + z) - z \times 3 \times x \\ = x \times y - 2 \times x \times z.

Proof. intros. ring. Qed.

End RINGDEMO.
```

31.6.3 Congruence

The tactic **congruence** is able to exploit equalities from the proof context in order to automatically perform the rewriting operations necessary to establish a goal. It is slightly more powerful than the tactic **subst**, which can only handle equalities of the form x = e where x is a variable and e an expression.

```
Lemma congruence_demo_1:
```

```
\forall (f: \mathbf{nat} \rightarrow \mathbf{nat} \rightarrow \mathbf{nat}) (g \ h: \mathbf{nat} \rightarrow \mathbf{nat}) (x \ y \ z: \mathbf{nat}), f(g \ x) (g \ y) = z \rightarrow 2 = g \ x \rightarrow g \ y = h \ z \rightarrow f(x) = z.
```

Proof. intros. congruence. Qed.

Moreover, congruence is able to exploit universally quantified equalities, for example \forall $a, g \ a = h \ a$.

```
Lemma congruence_demo_2:
```

```
\forall \ (f: \mathbf{nat} \rightarrow \mathbf{nat} \rightarrow \mathbf{nat}) \ (g \ h: \mathbf{nat} \rightarrow \mathbf{nat}) \ (x \ y \ z: \mathbf{nat}), (\forall \ a, \ g \ a = h \ a) \rightarrow f \ (g \ x) \ (g \ y) = z \rightarrow g \ x = 2 \rightarrow f \ 2 \ (h \ y) = z.
```

Proof. congruence. Qed.

Next is an example where congruence is very useful.

```
Lemma congruence_demo_4 : \forall (f g : nat \rightarrow nat),
```

```
 (\forall \ a, f \ a = g \ a) \rightarrow \\ f \ (g \ (g \ 2)) = g \ (f \ (f \ 2)).  Proof. congruence. Qed.
```

The tactic **congruence** is able to prove a contradiction if the goal entails an equality that contradicts an inequality available in the proof context.

Lemma congruence_demo_3:

```
\forall (f \ g \ h : \mathbf{nat} \rightarrow \mathbf{nat}) \ (x : \mathbf{nat}),

(\forall \ a, f \ a = h \ a) \rightarrow

g \ x = f \ x \rightarrow

g \ x \neq h \ x \rightarrow

False.
```

Proof. congruence. Qed.

One of the strengths of congruence is that it is a very fast tactic. So, one should not hesitate to invoke it wherever it might help.

31.7 Summary

Let us summarize the main automation tactics available.

- auto automatically applies reflexivity, assumption, and apply.
- eauto moreover tries eapply, and in particular can instantiate existentials in the conclusion.
- *iauto* extends **eauto** with support for negation, conjunctions, and disjunctions. However, its support for disjunction can make it exponentially slow.
- jauto extends eauto with support for negation, conjunctions, and existential at the head of hypothesis.
- congruence helps reasoning about equalities and inequalities.
- omega proves arithmetic goals with equalities and inequalities, but it does not support multiplication.
- ring proves arithmetic goals with multiplications, but does not support inequalities.

In order to set up automation appropriately, keep in mind the following rule of thumbs:

 automation is all about balance: not enough automation makes proofs not very robust on change, whereas too much automation makes proofs very hard to fix when they break.

- if a lemma is not goal directed (i.e., some of its variables do not occur in its conclusion), then the premises need to be ordered in such a way that proving the first premises maximizes the chances of correctly instantiating the variables that do not occur in the conclusion.
- a lemma whose conclusion is *False* should only be added as a local hint, i.e., as a hint within the current section.
- a transitivity lemma should never be considered as hint; if automation of transitivity reasoning is really necessary, an Extern Hint needs to be set up.
- a definition usually needs to be accompanied with a Hint Unfold.

Becoming a master in the black art of automation certainly requires some investment, however this investment will pay off very quickly.

Chapter 32

Library PE

32.1 PE: Partial Evaluation

Equiv.v introduced constant folding as an example of a program transformation and proved that it preserves the meaning of the program. Constant folding operates on manifest constants such as ANum expressions. For example, it simplifies the command Y ::= APlus $(ANum\ 3)\ (ANum\ 1)$ to the command $Y ::= ANum\ 4$. However, it does not propagate known constants along data flow. For example, it does not simplify the sequence $X ::= ANum\ 3$; $Y ::= APlus\ (AId\ X)\ (ANum\ 1)$ to $X ::= ANum\ 3$; $Y ::= ANum\ 4$ because it forgets that X is 3 by the time it gets to Y.

We naturally want to enhance constant folding so that it propagates known constants and uses them to simplify programs. Doing so constitutes a rudimentary form of partial evaluation. As we will see, partial evaluation is so called because it is like running a program, except only part of the program can be evaluated because only part of the input to the program is known. For example, we can only simplify the program X ::= ANum 3; Y ::= AMinus (APlus (AId X) (ANum 1)) (AId Y) to X ::= ANum 3; Y ::= AMinus (ANum 4) (AId Y) without knowing the initial value of Y.

Require Export Imp.
Require Import FunctionalExtensionality.

32.2 Generalizing Constant Folding

The starting point of partial evaluation is to represent our partial knowledge about the state. For example, between the two assignments above, the partial evaluator may know only that X is 3 and nothing about any other variable.

32.2.1 Partial States

Conceptually speaking, we can think of such partial states as the type $id \to option\ nat$ (as opposed to the type $id \to nat$ of concrete, full states). However, in addition to looking up and updating the values of individual variables in a partial state, we may also want to compare two partial states to see if and where they differ, to handle conditional control flow. It is not possible to compare two arbitrary functions in this way, so we represent partial states in a more concrete format: as a list of $id \times nat$ pairs.

```
Definition pe_state := list (id \times nat).
```

The idea is that a variable id appears in the list if and only if we know its current nat value. The pe_lookup function thus interprets this concrete representation. (If the same variable id appears multiple times in the list, the first occurrence wins, but we will define our partial evaluator to never construct such a pe_state .)

```
Fixpoint pe_lookup (pe\_st: pe\_state) (V:id): option nat := match <math>pe\_st with | [] \Rightarrow None | (V',n')::pe\_st \Rightarrow if beq\_id <math>V(V') then Some (n') = pe\_lookup (pe\_st) = pe\_lookup (pe\_st
```

For example, $empty_pe_state$ represents complete ignorance about every variable – the function that maps every id to None.

```
Definition empty_pe_state : pe_state := [].
```

More generally, if the *list* representing a pe_state does not contain some id, then that pe_state must map that id to None. Before we prove this fact, we first define a useful tactic for reasoning with id equality. The tactic compare V V' SCase means to reason by cases whether beq_id V V' is true or false. In the case where beq_id V V' = true, the tactic substitutes V for V' throughout.

```
Tactic Notation "compare" ident(i) ident(j) ident(c) := let H := fresh "Heq" i j in destruct (beq_id i j) as [|]eqn:H; [ Case\_aux c "equal"; symmetry in H; apply beq_id_eq in H; subst j | Case\_aux c "not equal" ].

Theorem pe_domain: \forall pe\_st V n, pe_lookup pe\_st V = Some n \rightarrow true = existsb (beq_id V) (map (@fst \_ \_) pe\_st).

Proof. intros pe\_st V n H. induction pe\_st as [|[V'] n'] pe\_st]. Case "[]". inversion H. Case "::". simpl in H. simpl. compare V V' SCase; auto. Qed.
```

32.2.2 Arithmetic Expressions

Partial evaluation of *aexp* is straightforward – it is basically the same as constant folding, *fold_constants_aexp*, except that sometimes the partial state tells us the current value of a variable and we can replace it by a constant expression.

```
Fixpoint pe_aexp (pe_st : pe_state) (a : aexp) : aexp :=
  match a with
   ANum n \Rightarrow ANum n
  | Ald i \Rightarrow \text{match pe_lookup } pe\_st i \text{ with }
                 | Some n \Rightarrow ANum n
                 None \Rightarrow Ald i
                end
  | APlus a1 \ a2 \Rightarrow
       match (pe_aexp pe_st a1, pe_aexp pe_st a2) with
       (ANum n1, ANum n2) \Rightarrow ANum (n1 + n2)
       (a1', a2') \Rightarrow APlus a1' a2'
  | AMinus a1 \ a2 \Rightarrow
       match (pe_aexp pe_st \ a1, pe_aexp pe_st \ a2) with
       (ANum n1, ANum n2) \Rightarrow ANum (n1 - n2)
       (a1', a2') \Rightarrow AMinus a1' a2'
       end
  | AMult a1 \ a2 \Rightarrow
       match (pe_aexp pe_st \ a1, pe_aexp pe_st \ a2) with
       (ANum n1, ANum n2) \Rightarrow ANum (n1 \times n2)
       (a1', a2') \Rightarrow \mathsf{AMult} \ a1' \ a2'
       end
  end.
    This partial evaluator folds constants but does not apply the associativity of addition.
Example test_pe_aexp1:
  pe_aexp[(X,3)] (APlus (APlus (Ald X) (ANum 1)) (Ald Y))
  = APlus (ANum 4) (Ald Y).
Proof. reflexivity. Qed.
Example text_pe_aexp2:
```

Now, in what sense is pe_aexp correct? It is reasonable to define the correctness of pe_aexp as follows: whenever a full state st:state is consistent with a partial state $pe_st:pe_state$ (in other words, every variable to which pe_st assigns a value is assigned the same value by st), evaluating a and evaluating pe_aexp pe_st a in st yields the same result. This statement is indeed true.

 $pe_aexp[(Y,3)](APlus(APlus(Ald X)(ANum 1))(Ald Y))$

= APlus (APlus (Ald X) (ANum 1)) (ANum 3).

Proof. reflexivity. Qed.

```
Definition pe_consistent (st:state) (pe\_st:pe\_state) := \forall \ V \ n, Some n = \text{pe\_lookup} \ pe\_st \ V \rightarrow st \ V = n.

Theorem pe_aexp_correct_weak: \forall \ st \ pe\_st, pe_consistent st \ pe\_st \rightarrow \forall \ a, aeval st \ a = \text{aeval} \ st \ (\text{pe\_aexp} \ pe\_st \ a).

Proof. unfold pe_consistent. intros st \ pe\_st \ H \ a.

aexp\_cases (induction a) Case; simpl;

try reflexivity;

try (destruct (pe_aexp pe\_st \ a1);

destruct (pe_aexp pe\_st \ a2);

rewrite IHa1; rewrite IHa2; reflexivity).

Case \ "AId".

remember (pe_lookup pe\_st \ i) as l. destruct l.

SCase \ "Some". rewrite H \ with \ (n:=n) by apply Heql. reflexivity.

Qed.
```

However, we will soon want our partial evaluator to remove assignments. For example, it will simplify X ::= ANum 3; Y ::= AMinus (AId X) (AId Y); X ::= ANum 4 to just Y ::= AMinus (ANum 3) (AId Y); X ::= ANum 4 by delaying the assignment to X until the end. To accomplish this simplification, we need the result of partial evaluating pe_aexp (X,3) (AMinus (AId X) (AId Y)) to be equal to AMinus (ANum 3) (AId Y) and not the original expression AMinus (AId X) (AId Y). After all, it would be incorrect, not just inefficient, to transform X ::= ANum 3; Y ::= AMinus (AId X) (AId Y); X ::= ANum 4 to Y ::= AMinus (AId X) (AId Y); X ::= ANum 4 even though the output expressions AMinus (ANum 3) (AId Y) and AMinus (AId X) (AId Y) both satisfy the correctness criterion that we just proved. Indeed, if we were to just define $pe_aexp_be_st = a$ then the theorem $pe_aexp_bcorrect$ would already trivially hold.

Instead, we want to prove that the pe_aexp is correct in a stronger sense: evaluating the expression produced by partial evaluation ($aeval\ st\ (pe_aexp\ pe_st\ a)$) must not depend on those parts of the full state $st\ that$ are already specified in the partial state pe_st . To be more precise, let us define a function $pe_override$, which updates $st\ with$ the contents of pe_st . In other words, $pe_override$ carries out the assignments listed in pe_st on top of st.

```
Fixpoint pe_override (st:state) (pe_-st:pe_state) : state := match pe_-st with | [] \Rightarrow st | (V,n)::pe_-st \Rightarrow update (pe_override st pe_-st) V n end. Example test_pe_override: pe_override (update empty_state Y 1) [(X,3),(Z,2)] = update (update (update empty_state Y 1) Z 2) X 3. Proof. reflexivity. Qed.
```

Although pe_override operates on a concrete list representing a pe_state, its behavior is

defined entirely by the pe_lookup interpretation of the pe_state .

```
Theorem pe_override_correct: \forall \ st \ pe\_st \ V0, pe_override st \ pe\_st \ V0 = match pe_lookup pe\_st \ V0 with | Some n \Rightarrow n | None \Rightarrow st \ V0 end. Proof. intros. induction pe\_st as [|[V \ n]] \ pe\_st]. reflexivity. simpl in *. unfold update. rewrite beq_id_sym. compare \ V0 \ V \ Case; auto. Qed.
```

We can relate $pe_consistent$ to $pe_override$ in two ways. First, overriding a state with a partial state always gives a state that is consistent with the partial state. Second, if a state is already consistent with a partial state, then overriding the state with the partial state gives the same state.

```
Theorem pe_override_consistent: \forall st \ pe\_st, pe_consistent (pe_override st \ pe\_st) \ pe\_st.

Proof. intros st \ pe\_st \ V \ n \ H. rewrite pe_override_correct. destruct (pe_lookup pe\_st \ V); inversion H. reflexivity. Qed. Theorem pe_consistent_override: \forall st \ pe\_st, pe_consistent st \ pe\_st \ \to \forall \ V, \ st \ V = \text{pe_override} \ st \ pe\_st \ V.

Proof. intros st \ pe\_st \ H \ V. rewrite pe_override_correct. remember (pe_lookup pe\_st \ V) as l. destruct l; auto. Qed.
```

Now we can state and prove that pe_aexp is correct in the stronger sense that will help us define the rest of the partial evaluator.

Intuitively, running a program using partial evaluation is a two-stage process. In the first, static stage, we partially evaluate the given program with respect to some partial state to get a residual program. In the second, dynamic stage, we evaluate the residual program with respect to the rest of the state. This dynamic state provides values for those variables that are unknown in the static (partial) state. Thus, the residual program should be equivalent to prepending the assignments listed in the partial state to the original program.

```
Theorem pe_aexp_correct: \forall \ (pe_-st: pe_-state) \ (a: aexp) \ (st: state), aeval (pe_override st \ pe_-st) \ a = aeval \ st \ (pe_aexp \ pe_-st \ a).

Proof.

intros pe_-st \ a \ st.

aexp_-cases (induction a) Case; simpl;

try reflexivity;

try (destruct (pe_aexp pe_-st \ a1);

destruct (pe_aexp pe_-st \ a2);

rewrite IHa1; rewrite IHa2; reflexivity).

rewrite pe_override_correct. destruct (pe_lookup pe_-st \ i); reflexivity.

Qed.
```

32.2.3 Boolean Expressions

The partial evaluation of boolean expressions is similar. In fact, it is entirely analogous to the constant folding of boolean expressions, because our language has no boolean variables.

```
Fixpoint pe_bexp (pe_-st: pe_state) (b: bexp): bexp :=
  \mathtt{match}\ b with
    BTrue \Rightarrow BTrue
    BFalse \Rightarrow BFalse
    BEq a1 \ a2 \Rightarrow
        match (pe_aexp pe_st \ a1, pe_aexp pe_st \ a2) with
        (ANum n1, ANum n2) \Rightarrow if beq_nat n1 n2 then BTrue else BFalse
        (a1', a2') \Rightarrow BEq a1' a2'
        end
  | BLe a1 a2 \Rightarrow
        match (pe_aexp pe_st \ a1, pe_aexp pe_st \ a2) with
        (ANum n1, ANum n2) \Rightarrow if ble_nat n1 n2 then BTrue else BFalse
        (a1', a2') \Rightarrow BLe a1' a2'
        end
  | BNot b1 \Rightarrow
        match (pe_bexp pe_st \ b1) with
          \mathsf{BTrue} \Rightarrow \mathsf{BFalse}
          \mathsf{BFalse} \Rightarrow \mathsf{BTrue}
        |b1' \Rightarrow BNot b1'
        end
  | BAnd b1 b2 \Rightarrow
        match (pe_bexp pe_st \ b1, pe_bexp pe_st \ b2) with
        | (BTrue, BTrue) \Rightarrow BTrue
        | (BTrue, BFalse) \Rightarrow BFalse
        | (BFalse, BTrue) \Rightarrow BFalse
         | (BFalse, BFalse) ⇒ BFalse
        |(b1', b2') \Rightarrow \mathsf{BAnd}\ b1'\ b2'
        end
  end.
Example test_pe_bexp1:
  pe_bexp[(X,3)] (BNot (BLe (Ald X) (ANum 3)))
  = BFalse.
Proof. reflexivity. Qed.
Example test_pe_bexp2: \forall b,
  b = \mathsf{BNot} \; (\mathsf{BLe} \; (\mathsf{AId} \; \mathsf{X}) \; (\mathsf{APlus} \; (\mathsf{AId} \; \mathsf{X}) \; (\mathsf{ANum} \; 1))) \to
  pe_bexp[]b = b.
Proof. intros b H. rewrite \rightarrow H. reflexivity. Qed.
```

The correctness of pe_bexp is analogous to the correctness of pe_aexp above.

```
Theorem pe_bexp_correct: \forall (pe_st:pe_state) (b:bexp) (st:state),
  beval (pe_override st \ pe_st) b = beval \ st \ (pe_bexp \ pe_st \ b).
Proof.
  intros pe_{-}st \ b \ st.
  bexp\_cases (induction b) Case; simpl;
    try reflexivity;
     try (remember (pe_aexp pe_st a) as a';
           remember (pe_aexp pe_st \ a\theta) as a\theta';
           assert (Ha: aeval (pe_override st \ pe_st) a = aeval \ st \ a');
           assert (Ha\theta: aeval (pe_override st pe_st) a\theta = aeval st a\theta');
             try (subst; apply pe_aexp_correct);
           destruct a'; destruct a\theta'; rewrite Ha; rewrite Ha\theta;
           simpl; try destruct (beq_nat n \ n\theta); try destruct (ble_nat n \ n\theta);
           reflexivity);
    try (destruct (pe_bexp pe_st b); rewrite IHb; reflexivity);
    try (destruct (pe_bexp pe_st b1);
           destruct (pe_bexp pe_st \ b2);
           rewrite IHb1; rewrite IHb2; reflexivity).
Qed.
```

32.3 Partial Evaluation of Commands, Without Loops

What about the partial evaluation of commands? The analogy between partial evaluation and full evaluation continues: Just as full evaluation of a command turns an initial state into a final state, partial evaluation of a command turns an initial partial state into a final partial state. The difference is that, because the state is partial, some parts of the command may not be executable at the static stage. Therefore, just as pe_aexp returns a residual aexp and pe_bexp returns a residual bexp above, partially evaluating a command yields a residual command.

Another way in which our partial evaluator is similar to a full evaluator is that it does not terminate on all commands. It is not hard to build a partial evaluator that terminates on all commands; what is hard is building a partial evaluator that terminates on all commands yet automatically performs desired optimizations such as unrolling loops. Often a partial evaluator can be coaxed into terminating more often and performing more optimizations by writing the source program differently so that the separation between static and dynamic information becomes more apparent. Such coaxing is the art of binding-time improvement. The binding time of a variable tells when its value is known – either "static", or "dynamic."

Anyway, for now we will just live with the fact that our partial evaluator is not a total function from the source command and the initial partial state to the residual command and the final partial state. To model this non-termination, just as with the full evaluation of commands, we use an inductively defined relation. We write c1 / st || c1' / st' to mean that partially evaluating the source command c1 in the initial partial state st yields the residual

command c1' and the final partial state st'. For example, we want something like (X ::= ANum 3; Y ::= AMult (AId Z) (APlus (AId X) (AId X))) / \square || (Y ::= AMult (AId Z) (ANum 6)) / (X,3) to hold. The assignment to X appears in the final partial state, not the residual command.

32.3.1 Assignment

Let's start by considering how to partially evaluate an assignment. The two assignments in the source program above needs to be treated differently. The first assignment X := ANum 3, is static: its right-hand-side is a constant (more generally, simplifies to a constant), so we should update our partial state at X to 3 and produce no residual code. (Actually, we produce a residual SKIP.) The second assignment Y := AMult (AId Z) (APlus (AId X) (AId X)) is dynamic: its right-hand-side does not simplify to a constant, so we should leave it in the residual code and remove Y, if present, from our partial state. To implement these two cases, we define the functions pe_add and pe_remove . Like $pe_override$ above, these functions operate on a concrete list representing a pe_state , but the theorems $pe_add_correct$ and $pe_remove_correct$ specify their behavior by the pe_lookup interpretation of the pe_state .

```
Fixpoint pe_remove (pe\_st:pe\_state) (V:id): pe\_state :=
  match pe_{-}st with
   [] \Rightarrow []
  (V', n'):: pe\_st \Rightarrow if beq\_id V V' then pe\_remove pe\_st V
                         else (V', n') :: pe_remove pe\_st\ V
  end.
Theorem pe_remove_correct: \forall pe\_st \ V \ V0,
  pe_lookup (pe_remove pe_st V) V\theta
  = if beg_id V V \theta then None else pe_lookup pe_st V \theta.
Proof. intros pe\_st\ V\ V0. induction pe\_st as [|\ [V'\ n']\ pe\_st].
  Case "[]". destruct (beq_id V V0); reflexivity.
  Case "::". simpl. compare V V' SCase.
    SCase "equal". rewrite IHpe_st.
      replace (beq_id V0 V) with (beq_id V V0) by apply beq_id_sym.
      destruct (beq_id V V\theta); reflexivity.
    SCase "not equal". simpl. compare V0 V' SSCase.
       SSCase "equal". rewrite HeqVV'. reflexivity.
       SSCase "not equal". rewrite IHpe_st. reflexivity.
Qed.
Definition pe_add (pe_st:pe_state) (V:id) (n:nat) : pe_state :=
  (V, n) :: pe_remove pe_st V.
Theorem pe_add_correct: \forall pe_st \ V \ n \ V0,
  pe_lookup (pe_add pe_st V n) V0
  = if beg_id V V\theta then Some n else pe_lookup pe_st V\theta.
Proof. intros pe\_st\ V\ n\ VO. unfold pe_add. simpl. rewrite beq_id_sym.
```

```
compare V V0 Case.
Case "equal". reflexivity.
Case "not equal". rewrite pe_remove_correct. rewrite HeqVV0. reflexivity.
Qed.
```

We will use the two theorems below to show that our partial evaluator correctly deals with dynamic assignments and static assignments, respectively.

```
Theorem pe_override_update_remove: \forall \ st \ pe\_st \ V \ n, update (pe_override st \ pe\_st) \ V \ n = pe_override (update st \ V \ n) (pe_remove pe\_st \ V). Proof. intros st \ pe\_st \ V \ n. apply functional_extensionality. intros V0. unfold update. rewrite !pe_override_correct. rewrite pe_remove_correct. destruct (beq_id V \ V0); reflexivity. Qed. Theorem pe_override_update_add: \forall \ st \ pe\_st \ V \ n, update (pe_override st \ pe\_st \ V \ n). Proof. intros st \ pe\_st \ V \ n. apply functional_extensionality. intros V0. unfold update. rewrite !pe_override_correct. rewrite pe_add_correct. destruct (beq_id V \ V0); reflexivity. Qed.
```

32.3.2 Conditional

Trickier than assignments to partially evaluate is the conditional, IFB b1 THEN c1 ELSE c2 FI. If b1 simplifies to BTrue or BFalse then it's easy: we know which branch will be taken, so just take that branch. If b1 does not simplify to a constant, then we need to take both branches, and the final partial state may differ between the two branches!

The following program illustrates the difficulty: X ::= ANum 3; IFB BLe (AId Y) (ANum 4) THEN Y ::= ANum 4; IFB BEq (AId X) (AId Y) THEN Y ::= ANum 999 ELSE SKIP FI ELSE SKIP FI Suppose the initial partial state is empty. We don't know statically how Y compares to 4, so we must partially evaluate both branches of the (outer) conditional. On the THEN branch, we know that Y is set to 4 and can even use that knowledge to simplify the code somewhat. On the ELSE branch, we still don't know the exact value of Y at the end. What should the final partial state and residual program be?

One way to handle such a dynamic conditional is to take the intersection of the final partial states of the two branches. In this example, we take the intersection of (Y,4),(X,3) and (X,3), so the overall final partial state is (X,3). To compensate for forgetting that Y is 4, we need to add an assignment $Y ::= ANum \ 4$ to the end of the THEN branch. So, the residual program will be something like SKIP; IFB BLe (AId Y) (ANum 4) THEN SKIP; SKIP; $Y ::= ANum \ 4$ ELSE SKIP FI

Programming this case in Coq calls for several auxiliary functions: we need to compute the intersection of two pe_states and turn their difference into sequences of assignments.

First, we show how to compute whether two pe_states to disagree at a given variable. In the theorem $pe_disagree_domain$, we prove that two pe_states can only disagree at variables

```
that appear in at least one of them.
```

```
Definition pe_disagree_at (pe\_st1 \ pe\_st2 : pe\_state) \ (V:id) : bool :=
  match pe_lookup pe\_st1 V, pe_lookup pe\_st2 V with
   Some x, Some y \Rightarrow \text{negb} (beg_nat x y)
   None, None \Rightarrow false
  | \_, \_ \Rightarrow \mathsf{true}
  end.
Lemma existsb_app: \forall X (f:X \rightarrow bool) l1 l2,
  existsb f(l1 ++ l2) = \text{orb} \text{ (existsb } f(l1) \text{ (existsb } f(l2)).}
Proof. intros X f l1 l2. induction l1. reflexivity.
  simpl. rewrite IHl1. rewrite orb_assoc. reflexivity. Qed.
Theorem pe_disagree_domain: \forall (pe\_st1 \ pe\_st2 : pe\_state) \ (V:id),
  true = pe_disagree_at pe_st1 pe_st2 V \rightarrow
  true = existsb (beq_id V) (map (@fst _ _) pe_st1 ++
                                   map (@fst _ _) pe_st2).
Proof. unfold pe_disagree_at. intros pe_st1 pe_st2 V H.
  rewrite existsb_app. symmetry. apply orb_true_intro.
  remember (pe_lookup pe_st1 V) as lookup1.
  destruct lookup1 as [n1]. left. symmetry. apply pe_domain with n1. auto.
  remember (pe_lookup pe_st2 V) as lookup2.
  destruct lookup2 as [n2]. right. symmetry. apply pe_domain with n2. auto.
  inversion H. Qed.
```

We define the $pe_compare$ function to list the variables where two given pe_states disagree. This list is exact, according to the theorem $pe_compare_correct$: a variable appears on the list if and only if the two given pe_states disagree at that variable. Furthermore, we use the pe_unique function to eliminate duplicates from the list.

```
Theorem pe_unique_correct: \forall l x,
  existsb (beq_id x) l = existsb (beq_id x) (pe_unique l).
Proof. intros l x. induction l as [|h|t]. reflexivity.
  simpl in *. compare x h Case.
  Case "equal". reflexivity.
  Case "not equal".
    rewrite \rightarrow existsb_beg_id_filter, \leftarrow IHt, \rightarrow beg_id_sym, \rightarrow Hegxh,
              → andb_true_r. reflexivity. Qed.
Definition pe_compare (pe\_st1 \ pe\_st2 : pe\_state) : list id :=
  pe_unique (filter (pe_disagree_at pe_st1 pe_st2)
    (map (@fst \_ \_) pe\_st1 ++ map (@fst \_ \_) pe\_st2)).
Theorem pe_compare_correct: \forall pe\_st1 \ pe\_st2 \ V,
  pe_lookup pe_st1 V = pe_lookup <math>pe_st2 V \leftrightarrow
  false = existsb (beq_id V) (pe_compare pe\_st1 pe\_st2).
Proof. intros pe_-st1 pe_-st2 V.
  unfold pe_compare. rewrite ← pe_unique_correct, → existsb_beg_id_filter.
  split; intros Heq.

```

The intersection of two partial states is the result of removing from one of them all the variables where the two disagree. We define the function $pe_removes$, in terms of pe_remove above, to perform such a removal of a whole list of variables at once.

The theorem $pe_compare_removes$ testifies that the pe_lookup interpretation of the result of this intersection operation is the same no matter which of the two partial states we remove the variables from. Because $pe_override$ only depends on the pe_lookup interpretation of

partial states, $pe_override$ also does not care which of the two partial states we remove the variables from; that theorem $pe_compare_override$ is used in the correctness proof shortly.

```
Fixpoint pe_removes (pe_st:pe_state) (ids: list id): pe_state :=
  match ids with
   [] \Rightarrow pe\_st
  V::ids \Rightarrow pe\_remove (pe\_removes pe\_st ids) V
  end.
Theorem pe_removes_correct: \forall pe_st ids V,
  pe_lookup (pe_removes pe_st ids) V =
  if existsb (beq_id V) ids then None else pe_lookup pe_-st V.
Proof. intros pe_st ids V. induction ids as [V' ids]. reflexivity.
  simpl. rewrite pe_remove_correct. rewrite IHids.
  replace (beq_id V' V) with (beq_id V V') by apply beq_id_sym.
  destruct (beg_id V V'); destruct (existsb (beg_id V) ids); reflexivity.
Qed.
Theorem pe_compare_removes: \forall pe\_st1 \ pe\_st2 \ V,
  pe_lookup (pe_removes pe_st1 (pe_compare pe_st1 pe_st2)) V =
  pe_lookup (pe_removes pe_st2 (pe_compare pe_st1 pe_st2)) V.
Proof. intros pe_st1 pe_st2 V. rewrite !pe_removes_correct.
  remember (existsb (beq_id V) (pe_compare pe_st1 pe_st2)) as b.
  destruct b. reflexivity.
  apply pe\_compare\_correct in Heqb. apply <math>Heqb. Qed.
Theorem pe_compare_override: \forall pe\_st1 \ pe\_st2 \ st,
  pe_override st (pe_removes pe\_st1 (pe_compare pe\_st1 pe\_st2)) =
  pe_override st (pe_removes pe_-st2 (pe_compare pe_-st1 pe_-st2)).
Proof. intros. apply functional_extensionality. intros V.
  rewrite !pe_override_correct. rewrite pe_compare_removes. reflexivity.
Qed.
```

Finally, we define an assign function to turn the difference between two partial states into a sequence of assignment commands. More precisely, assign pe_st ids generates an assignment command for each variable listed in ids.

```
Fixpoint assign (pe\_st: pe\_state) (ids: list id): com:= match ids with | [] \Rightarrow SKIP | V::ids \Rightarrow match pe\_lookup pe\_st V with | Some n \Rightarrow (assign pe\_st ids; V::= ANum n) | None \Rightarrow assign pe\_st ids end end.
```

The command generated by assign always terminates, because it is just a sequence of assignments. The (total) function assigned below computes the effect of the command on the

(dynamic state). The theorem assign_removes then confirms that the generated assignments perfectly compensate for removing the variables from the partial state.

```
Definition assigned (pe\_st:pe\_state) (ids: list id) (st:state): state :=
  fun V \Rightarrow \text{match existsb} (beg_id V) ids, pe_lookup pe_st V with
             | true, Some n \Rightarrow n
             | \_, \_ \Rightarrow st \ V
Theorem assign_removes: \forall pe\_st \ ids \ st,
  pe_override st pe_st =
  pe_override (assigned pe_st\ ids\ st) (pe_removes pe_st\ ids).
Proof. intros pe_st ids st. apply functional_extensionality. intros V.
  rewrite !pe_override_correct. rewrite pe_removes_correct. unfold assigned.
  destruct (existsb (beq_id V)); destruct (pe_lookup pe_st V); reflexivity.

32.3.3 The Partial Evaluation Relation

At long last, we can define a partial evaluator for commands without loops, as an inductive relation! The inequality conditions in $PE_AssDynamic$ and PE_If are just to keep the partial evaluator deterministic; they are not required for correctness.

```
Reserved Notation "c1 '/' st '||' c1' '/' st'"
```

```
(at level 40, st at level 39, c1' at level 39).
Inductive pe\_com : com \rightarrow pe\_state \rightarrow com \rightarrow pe\_state \rightarrow Prop :=
  \mid \mathsf{PE\_Skip} : \forall \ pe\_st,
        SKIP / pe_st | SKIP / pe_st
  \mid \mathsf{PE\_AssStatic} : \forall \ pe\_st \ a1 \ n1 \ l,
        pe_aexp pe_st \ a1 = ANum \ n1 \rightarrow
        (l := a1) / pe\_st \mid \mid SKIP / pe\_add pe\_st l n1
  \mid \mathsf{PE\_AssDynamic} : \forall pe\_st \ a1 \ a1' \ l,
        pe_aexp pe_st a1 = a1' \rightarrow
        (\forall n, a1' \neq \mathsf{ANum}\ n) \rightarrow
        (l ::= a1) / pe\_st \mid \mid (l ::= a1') / pe\_remove pe\_st l
  | PE\_Seq : \forall pe\_st pe\_st' pe\_st'' c1 c2 c1' c2',
        c1 / pe\_st \mid \mid c1' / pe\_st' \rightarrow
        c2 / pe_st' \mid \mid c2' / pe_st'' \rightarrow
        (c1; c2) / pe_st \mid \mid (c1'; c2') / pe_st''
  \mid \mathsf{PE\_IfTrue} : \forall \ pe\_st \ pe\_st' \ b1 \ c1 \ c2 \ c1',
        pe_bexp pe_st b1 = BTrue \rightarrow
        c1 / pe_st \mid \mid c1' / pe_st' \rightarrow
        (IFB b1 THEN c1 ELSE c2 FI) / pe_-st || c1' / pe_-st'
  \mid \mathsf{PE\_IfFalse} : \forall \ pe\_st \ pe\_st' \ b1 \ c1 \ c2 \ c2',
        pe_bexp pe_st b1 = BFalse \rightarrow
        c2 / pe\_st \mid \mid c2' / pe\_st' \rightarrow
        (IFB b1 THEN c1 ELSE c2 FI) / pe\_st | | c2' / pe\_st'
  | PE_If : \forall pe_st pe_st1 pe_st2 b1 c1 c2 c1' c2',
        pe_bexp pe_st b1 \neq BTrue \rightarrow
        pe_bexp pe_st b1 \neq BFalse \rightarrow
        c1 / pe\_st \mid \mid c1' / pe\_st1 \rightarrow
        c2 / pe\_st \mid \mid c2' / pe\_st2 \rightarrow
        (IFB b1 THEN c1 ELSE c2 FI) / pe\_st
           || (IFB pe_bexp pe_st b1
                  THEN c1'; assign pe\_st1 (pe_compare pe\_st1 pe\_st2)
                  ELSE c2'; assign pe\_st2 (pe_compare pe\_st1 pe\_st2) FI)
                / pe_removes pe\_st1 (pe_compare pe\_st1 pe\_st2)
  where "c1',' st'||' c1'',' st'" := (pe_com c1 \ st \ c1' \ st').
Tactic Notation "pe_com_cases" tactic(first) ident(c) :=
  first;
   [ Case_aux c "PE_Skip"
    Case_aux c "PE_AssStatic" | Case_aux c "PE_AssDynamic"
    Case\_aux \ c \ "PE\_Seq"
    Case_aux c "PE_IfTrue" | Case_aux c "PE_IfFalse" | Case_aux c "PE_If" ].
Hint Constructors pe_com.
```

32.3.4 Examples

Below are some examples of using the partial evaluator. To make the pe_com relation actually usable for automatic partial evaluation, we would need to define more automation tactics in Coq. That is not hard to do, but it is not needed here.

```
Example pe_example1:
  (X ::= ANum 3 ; Y ::= AMult (Ald Z) (APlus (Ald X) (Ald X)))
  /[] || (SKIP; Y ::= AMult (Ald Z) (ANum 6)) / [(X,3)].
Proof. eapply PE_Seq. eapply PE_AssStatic. reflexivity.
  eapply PE_AssDynamic. reflexivity. intros n H. inversion H. Qed.
Example pe_example2:
  (X ::= ANum 3 ; IFB BLe (Ald X) (ANum 4) THEN X ::= ANum 4 ELSE SKIP FI)
  /[] || (SKIP; SKIP) / [(X,4)].
Proof. eapply PE_Seq. eapply PE_AssStatic. reflexivity.
  eapply PE_IfTrue. reflexivity.
  eapply PE_AssStatic. reflexivity. Qed.
Example pe_example3:
  (X ::= ANum 3;
   IFB BLe (Ald Y) (ANum 4) THEN
     Y ::= ANum 4;
     IFB BEq (Ald X) (Ald Y) THEN Y ::= ANum 999 ELSE SKIP FI
   ELSE SKIP FI) / []
  | | (SKIP;
       IFB BLe (Ald Y) (ANum 4) THEN
          (SKIP; SKIP); (SKIP; Y ::= ANum 4)
       ELSE SKIP; SKIP FI)
      / [(X,3)].
Proof. erewrite f_equal2 with (f := \text{fun } c \ st \Rightarrow \_ / \_ | | c / st).
  eapply PE_Seq. eapply PE_AssStatic. reflexivity.
  eapply PE_If; intuition eauto; try solve by inversion.
  econstructor. eapply PE_AssStatic. reflexivity.
  eapply PE_IfFalse. reflexivity. econstructor.
  reflexivity. reflexivity. Qed.
```

32.3.5 Correctness of Partial Evaluation

```
Finally let's prove that this partial evaluator is correct!
```

32.4 Partial Evaluation of Loops

It may seem straightforward at first glance to extend the partial evaluation relation pe_com above to loops. Indeed, many loops are easy to deal with. Considered this repeated-squaring loop, for example: WHILE BLe (ANum 1) (AId X) DO Y ::= AMult (AId Y) (AId Y); X ::= AMinus (AId X) (ANum 1) END If we know neither X nor Y statically, then the entire loop is dynamic and the residual command should be the same. If we know X but not Y, then the loop can be unrolled all the way and the residual command should be Y ::= AMult (AId Y) (AId Y); Y ::= AMult (AId Y) (AId Y) if X is initially 3 (and finally 0). In general, a loop is easy to partially evaluate if the final partial state of the loop body is equal to the initial state, or if its guard condition is static.

But there are other loops for which it is hard to express the residual program we want in Imp. For example, take this program for checking if Y is even or odd: X ::= ANum 0; WHILE BLe (ANum 1) (AId Y) DO Y ::= AMinus (AId Y) (ANum 1); X ::= AMinus (ANum 1) (AId X) END The value of X alternates between 0 and 1 during the loop. Ideally, we would like to unroll this loop, not all the way but two-fold, into something like WHILE BLe (ANum 1) (AId Y) DO Y ::= AMinus (AId Y) (ANum 1); IF BLe (ANum 1) (AId Y) THEN Y ::= AMinus (AId Y) (ANum 1) ELSE X ::= ANum 1; EXIT FI END; X ::= ANum 0 Unfortunately, there is no EXIT command in Imp. Without extending the range of control structures available in our language, the best we can do is to repeat loop-guard tests or add flag variables. Neither option is terribly attractive.

Still, as a digression, below is an attempt at performing partial evaluation on Imp commands. We add one more command argument c" to the pe_com relation, which keeps track of a loop to roll up.

Module LOOP.

32.4.2 Correctness

Because this partial evaluator can unroll a loop n-fold where n is a (finite) integer greater than one, in order to show it correct we need to perform induction not structurally on dynamic evaluation but on the number of times dynamic evaluation enters a loop body.

```

32.5 Partial Evaluation of Flowchart Programs

Instead of partially evaluating WHILE loops directly, the standard approach to partially evaluating imperative programs is to convert them into flowcharts. In other words, it turns out that adding labels and jumps to our language makes it much easier to partially evaluate. The result of partially evaluating a flowchart is a residual flowchart. If we are lucky, the jumps in the residual flowchart can be converted back to WHILE loops, but that is not possible in general; we do not pursue it here.

32.5.1 Basic blocks

A flowchart is made of *basic blocks*, which we represent with the inductive type *block*. A basic block is a sequence of assignments (the constructor Assign), concluding with a conditional jump (the constructor If) or an unconditional jump (the constructor Goto). The destinations of the jumps are specified by labels, which can be of any type. Therefore, we parameterize the block type by the type of labels.

```
Inductive block (Label:Type): Type:=

| Goto: Label 	o block \ Label
| If: bexp 	o Label 	o Label 	o block \ Label
| Assign: id 	o aexp 	o block \ Label 	o block \ Label.

Tactic Notation "block_cases" tactic(first) \ ident(c) := first;
| Case\_aux \ c "Goto" | Case\_aux \ c "If" | Case\_aux \ c "Assign" ].

Implicit Arguments Goto [[Label]].

Implicit Arguments Assign [[Label]].
```

We use the "even or odd" program, expressed above in Imp, as our running example. Converting this program into a flowchart turns out to require 4 labels, so we define the following type.

```
Inductive parity_label : Type :=
  | entry : parity_label
  | loop : parity_label
  | body : parity_label
  | done : parity_label.
```

The following block is the basic block found at the body label of the example program.

```
Definition parity_body : block parity_label :=
Assign Y (AMinus (Ald Y) (ANum 1))
  (Assign X (AMinus (ANum 1) (Ald X))
        (Goto loop)).
```

To evaluate a basic block, given an initial state, is to compute the final state and the label to jump to next. Because basic blocks do not *contain* loops or other control structures, evaluation of basic blocks is a total function – we don't need to worry about non-termination.

```
Fixpoint keval {L:Type} (st:state) (k: block L): state \times L:= match k with \mid Goto l\Rightarrow (st, l) \mid If b l1 l2\Rightarrow (st, if beval <math>st b then l1 else l2) \mid Assign i a k\Rightarrow keval (update st i (aeval st a)) k end
```

Example keval_example:

```
keval empty_state parity_body
= (update (update empty_state Y 0) X 1, loop).
Proof. reflexivity. Qed.
```

32.5.2 Flowchart programs

A flowchart program is simply a lookup function that maps labels to basic blocks. Actually, some labels are *halting states* and do not map to any basic block. So, more precisely, a flowchart program whose labels are of type L is a function from L to option (block L).

```
Definition program (L:Type): Type := L \to \operatorname{option} (block L). Definition parity: program \operatorname{parity\_label} := \operatorname{fun} l \Rightarrow \operatorname{match} l with |\operatorname{entry} \Rightarrow \operatorname{Some} (\operatorname{Assign} \mathsf{X} (\operatorname{ANum} 0) (\operatorname{Goto} \operatorname{loop})) | \operatorname{loop} \Rightarrow \operatorname{Some} (\operatorname{If} (\operatorname{BLe} (\operatorname{ANum} 1) (\operatorname{Ald} \mathsf{Y})) \operatorname{body} \operatorname{done}) | \operatorname{body} \Rightarrow \operatorname{Some} \operatorname{parity\_body} | \operatorname{done} \Rightarrow \operatorname{None} \operatorname{end}.
```

Unlike a basic block, a program may not terminate, so we model the evaluation of programs by an inductive relation *peval* rather than a recursive function.

```
Inductive peval \{L:Type\}\ (p:program\ L)
  : state \rightarrow L \rightarrow state \rightarrow L \rightarrow Prop :=
  \mid \mathsf{E}_{-}\mathsf{None}: \ \forall \ \mathit{st} \ \mathit{l},
     p l = None \rightarrow
     peval p st l st l
  | E_Some: \forall st \ l \ k \ st' \ l' \ st'' \ l'',
     p \ l = Some \ k \rightarrow
     keval st k = (st', l') \rightarrow
     peval p \ st' \ l' \ st'' \ l'' \rightarrow
     peval p st l st'' l''.
Example parity_eval: peval parity empty_state entry empty_state done.
Proof. erewrite f_equal with (f := \text{fun } st \Rightarrow \text{peval} \_ \_ \_ st \_).
  eapply E_Some. reflexivity. reflexivity.
  eapply E_Some. reflexivity. reflexivity.
  apply E_None. reflexivity.
  apply functional_extensionality. intros i. rewrite update_same; auto.
Qed.
Tactic Notation "peval_cases" tactic(first) ident(c) :=
  first:
  [ Case\_aux \ c "E_None" | Case\_aux \ c "E_Some" ].
```

32.5.3 Partial evaluation of basic blocks and flowchart programs

Partial evaluation changes the label type in a systematic way: if the label type used to be L, it becomes $pe_state \times L$. So the same label in the original program may be unfolded, or blown up, into multiple labels by being paired with different partial states. For example, the label loop in the parity program will become two labels: ([(X,0)], loop) and ([(X,1)], loop). This change of label type is reflected in the types of pe_block and $pe_program$ defined presently.

```
Fixpoint pe_block {L:Type} (pe_-st:pe_state) (k : block L)
  : block (pe_state × L) :=
  \mathtt{match}\ k with
   Goto l \Rightarrow \text{Goto } (pe\_st, l)
  | If b l1 l2 \Rightarrow
     match pe_bexp pe_st b with
     | BTrue \Rightarrow Goto (pe_-st, l1)
      BFalse \Rightarrow Goto (pe_st, l2)
     |b' \Rightarrow |fb'| (pe_st, l1) (pe_st, l2)
     end
  | Assign i \ a \ k \Rightarrow
    match pe_aexp pe_st a with
     ANum n \Rightarrow \text{pe\_block (pe\_add } pe\_st \ i \ n) \ k
     | a' \Rightarrow Assign \ i \ a' \ (pe_block \ (pe_remove \ pe_st \ i) \ k)
     end
  end.
Example pe_block_example:
  pe_block [(X,0)] parity_body
  = Assign Y (AMinus (Ald Y) (ANum 1)) (Goto ([(X,1)], loop)).
Proof. reflexivity. Qed.
Theorem pe_block_correct: \forall (L:Type) st pe_st k st' pe_st' (l':L),
  keval st (pe_block pe_st k) = (st', (pe_st', l')) \rightarrow
  keval (pe_override st pe_st) k = (pe_override st pe_st, l).
Proof. intros. generalize dependent pe_-st. generalize dependent st.

Chapter 34

Library Extraction2

34.1 Extraction2: Extracting ML from Coq, Part 2

Let's take a look at a slightly fancier way of using Coq's extraction facilities. Instead of translating a functional program in Coq into a functional program in OCaml, we'll extract the computational content of an interesting proof – the proof that the STLC is normalizing. The result will be an evaluator that takes well-typed STLC terms to their final normal forms.

Note that this is a slightly unusual way of using Coq. In the words of Adam Chlipala...

Many fans of the Curry-Howard correspondence support the idea of extracting programs from proofs. In reality, few users of Coq and related tools do any such thing. Instead, extraction is better thought of as an optimization that reduces the runtime costs of expressive typing. (Chlipala, CPDT)

However, it's interesting to see that it's possible at all! (And to think about what the extracted program does.)

34.2 Extracting a Normalizer

Require Import Extraction.
Require Import NormInType.

The *NormInType* module is a variant of the *Norm* module with a few significant differences. The essential point is that, during extraction, everything to do with Prop is *erased*. So, to extract a normalizer from a proof of normalization, we need to carry out the essential bits of the normalization proof in Type rather than Prop.

NormInType also incorporates a copy of the STLC typechecking function from the Type-checking module and its proof of correctness. (The function itself is no different from before, and the correctness proof has just a few small differences because of the changes we made to the basic definitions of STLC.) We need these things because the proof of normalization proceeds by induction on a typing derivation, so the extracted normalization function must

be passed a data structure representing a typing derivation. In *normdriver.ml*, we obtain this derivation from the proof that the typechecking algorithm is sound.

 ${\tt Extraction "norm.ml"} \ normalization \ type_check \ type_checking_sound.$

Take a look at *normdriver.ml* to see how this plumbing works in detail.

Finally, we can compile and execute our normalizer in the same way as we did with our evaluator for Imp.

ocamlc -w -20 -o normdriver norm.mli norm.ml normdriver.ml ./normdriver

Chapter 35

Library NormInType

35.1 NormInType: Alternate Version of Normalization, for Extraction

35.2 Note

This is an alternate version of *Norm.v* that is used as an example in *Extraction2.v*. It is not intended to be read on its own.

35.3 Normalization

Require Import Stlc.

(This chapter is optional.)

In this chapter, we consider another fundamental theoretical property of the simply typed lambda-calculus: the fact that the evaluation of a well-typed program is guaranteed to halt in a finite number of steps—i.e., every well-typed term is *normalizable*.

Unlike the type-safety properties we have considered so far, the normalization property does not extend to full-blown programming languages, because these languages nearly always extend the simply typed lambda-calculus with constructs, such as general recursion (as we discussed in the MoreStlc chapter) or recursive types, that can be used to write non-terminating programs. However, the issue of normalization reappears at the level of types when we consider the metatheory of polymorphic versions of the lambda calculus such as F_omega: in this system, the language of types effectively contains a copy of the simply typed lambda-calculus, and the termination of the typechecking algorithm will hinge on the fact that a "normalization" operation on type expressions is guaranteed to terminate.

Another reason for studying normalization proofs is that they are some of the most beautiful—and mind-blowing—mathematics to be found in the type theory literature, often (as here) involving the fundamental proof technique of *logical relations*.

The calculus we shall consider here is the simply typed lambda-calculus over a single base type bool and with pairs. We'll give full details of the development for the basic lambda-calculus terms treating bool as an uninterpreted base type, and leave the extension to the boolean operators and pairs to the reader. Even for the base calculus, normalization is not entirely trivial to prove, since each reduction of a term can duplicate redexes in subterms.

Exercise: 1 star Where do we fail if we attempt to prove normalization by a straightforward induction on the size of a well-typed term?

35.4 Language

We begin by repeating the relevant language definition, which is similar to those in the MoreStlc chapter, and supporting results including type preservation and step determinism. (We won't need progress.) You may just wish to skip down to the Normalization section...

Syntax and Operational Semantics

35.5 Normalization

Now for the actual normalization proof.

Our goal is to prove that every well-typed term evaluates to a normal form. In fact, it turns out to be convenient to prove something slightly stronger, namely that every well-typed term evaluates to a *value*. This follows from the weaker property anyway via the Progress lemma (why?) but otherwise we don't need Progress, and we didn't bother re-proving it above.

```
Here's the key definition:
```

```
Definition halts (t:tm): Type := (\exists \ t': tm, \ (t ==>* \ t') \times value \ t') \% type. A trivial fact:

Lemma value_halts: \forall \ v, value v \to halts \ v.

Proof.

intros v \ H. unfold halts.
```

```
∃ v. split.

apply multi_refl.

assumption.

Qed.
```

The key issue in the normalization proof (as in many proofs by induction) is finding a strong enough induction hypothesis. To this end, we begin by defining, for each type T, a set $R_{-}T$ of closed terms of type T. We will specify these sets using a relation R and write R T t when t is in $R_{-}T$. (The sets $R_{-}T$ are sometimes called saturated sets or reducibility candidates.)

Here is the definition of R for the base language:

- R bool t iff t is a closed term of type bool and t halts in a value
- $R(T1 \to T2)$ t iff t is a closed term of type $T1 \to T2$ and t halts in a value and for any term s such that R(T1) s, we have R(T2) (t s).

This definition gives us the strengthened induction hypothesis that we need. Our primary goal is to show that all *programs*—i.e., all closed terms of base type—halt. But closed terms of base type can contain subterms of functional type, so we need to know something about these as well. Moreover, it is not enough to know that these subterms halt, because the application of a normalized function to a normalized argument involves a substitution, which may enable more evaluation steps. So we need a stronger condition for terms of functional type: not only should they halt themselves, but, when applied to halting arguments, they should yield halting results.

The form of R is characteristic of the logical relations proof technique. (Since we are just dealing with unary relations here, we could perhaps more properly say logical predicates.) If we want to prove some property P of all closed terms of type A, we proceed by proving, by induction on types, that all terms of type A possess property P, all terms of type $A \rightarrow A$ preserve property P, all terms of type $(A \rightarrow A) - (A \rightarrow A)$ preserve the property of preserving property P, and so on. We do this by defining a family of predicates, indexed by types. For the base type A, the predicate is just P. For functional types, it says that the function should map values satisfying the predicate at the input type to values satisfying the predicate at the output type.

When we come to formalize the definition of R in Coq, we hit a problem. The most obvious formulation would be as a parameterized Inductive proposition like this:

Inductive $R: ty -> tm -> Prop := | R_bool : forall b t, has_type empty t TBool -> halts t -> R TBool t | R_arrow : forall T1 T2 t, has_type empty t (TArrow T1 T2) -> halts t -> (forall s, R T1 s -> R T2 (tapp t s)) -> R (TArrow T1 T2) t.$

Unfortunately, Coq rejects this definition because it violates the *strict positivity require*ment for inductive definitions, which says that the type being defined must not occur to the left of an arrow in the type of a constructor argument. Here, it is the third argument to R_arrow , namely $(\forall s, R \ T1 \ s \rightarrow R \ TS \ (tapp \ t \ s))$, and specifically the $R \ T1 \ s$ part, that violates this rule. (The outermost arrows separating the constructor arguments don't count when applying this rule; otherwise we could never have genuinely inductive predicates at all!) The reason for the rule is that types defined with non-positive recursion can be used to build non-terminating functions, which as we know would be a disaster for Coq's logical soundness. Even though the relation we want in this case might be perfectly innocent, Coq still rejects it because it fails the positivity test.

Fortunately, it turns out that we can define R using a Fixpoint:

```
Fixpoint R (T:ty) (t:tm) {struct T} : Type := (has_type empty t T × (halts t × (match T with | TBool \Rightarrow True | TArrow T1 T2 \Rightarrow (\forall s, R T1 s \rightarrow R T2 (tapp t s)) end))) % type.
```

As immediate consequences of this definition, we have that every element of every set $R_{-}T$ halts in a value and is closed with type t:

```
Lemma R_halts : \forall { T } {t}, R T t \rightarrow halts t. Proof.
```

intros. destruct T; unfold R in X; inversion X; inversion X1; subst; assumption. Qed.

```
Lemma R_typable_empty : \forall { T} {t}, R T t \rightarrow has_type empty t T. Proof.
```

intros. destruct T; unfold R in X; inversion X; inversion X1; assumption. $\mathsf{Qed}.$

Now we proceed to show the main result, which is that every well-typed term of type T is an element of R_-T . Together with R_-halts , that will show that every well-typed term halts in a value.

35.5.1 Membership in $R_{-}T$ is invariant under evaluation

We start with a preliminary lemma that shows a kind of strong preservation property, namely that membership in $R_{-}T$ is *invariant* under evaluation. We will need this property in both directions, i.e. both to show that a term in $R_{-}T$ stays in $R_{-}T$ when it takes a forward step, and to show that any term that ends up in $R_{-}T$ after a step must have been in $R_{-}T$ to begin with.

First of all, an easy preliminary lemma. Note that in the forward direction the proof depends on the fact that our language is determinstic. This lemma might still be true for non-deterministic languages, but the proof would be harder!

```
Definition iff (P \ Q : \mathsf{Type}) := ((P \to Q) \times (Q \to P)) \% \ type. Notation "P <-> Q" := (iff P \ Q) (at level 95, no associativity) : type\_scope.
```

```
Theorem ex_falso_quodlibet : \forall (P:Type),
  False \rightarrow P.
Proof.
  intros P contra.
  inversion contra. Qed.
Lemma step_preserves_halting : \forall t \ t', (t ==> t') \rightarrow (halts \ t \leftrightarrow halts \ t').
Proof.
 intros t t ST. unfold halts.
 split.
 Case "->".
  intros [t'' [STM \ V]].
  inversion STM; subst.
    apply ex_falso_quodlibet. apply value__normal in V. unfold normal_form in V. apply
V. \exists t'. auto.
   rewrite (step_deterministic \_ \_ \_ ST H). \exists t". split; assumption.
 Case "<-".
  intros [t'\theta \ [STM \ V]].
  \exists t'0. \text{ split}; \text{ eauto}.
  eapply multi_step. eassumption. assumption.
Qed.
```

Now the main lemma, which comes in two parts, one for each direction. Each proceeds by induction on the structure of the type T. In fact, this is where we make fundamental use of the finiteness of types.

One requirement for staying in $R_{-}T$ is to stay in type T. In the forward direction, we get this from ordinary type Preservation.

```
Lemma step_preserves_R: \forall \ T \ t \ t', \ (t ==> t') \rightarrow \mathsf{R} \ T \ t \rightarrow \mathsf{R} \ T \ t'. Proof. induction T; intros t \ t' \ E \ Rt; unfold \mathsf{R}; fold \mathsf{R}; unfold \mathsf{R} in Rt; fold \mathsf{R} in Rt; destruct Rt as [typable\_empty\_t \ [halts\_t \ RRt]]. split. eapply preservation; eauto. split. apply (step_preserves_halting \_ \_E); eauto. auto. split. apply preservation; eauto. split. apply (step_preserves_halting \_ \_E); eauto. intros. eapply IHT2. apply ST\_App1. apply E. apply RRt; auto. Qed.
```

The generalization to multiple steps is trivial:

Lemma multistep_preserves_ $R : \forall T \ t \ t'$,

```
(t ==>* t') \rightarrow R T t \rightarrow R T t'.
Proof.
  intros T t t' STM; induction STM; intros.
  assumption.
  apply IHSTM. eapply step_preserves_R. apply r. assumption.
Qed.
   In the reverse direction, we must add the fact that t has type T before stepping as an
additional hypothesis.
Lemma step_preserves_R' : \forall T \ t \ t',
  has_type empty t \ T \rightarrow (t \Longrightarrow t') \rightarrow R \ T \ t' \rightarrow R \ T \ t.
Proof.
  induction T; intros t t' typable_empty_t E Rt'; unfold R; fold R;
                  unfold R in Rt'; fold R in Rt';
                  destruct Rt' as [typable\_empty\_t' [halts\_t' RRt']].
  split. assumption.
  split. apply (step_preserves_halting _ _ E); eauto.
  auto.
  split. assumption.
  split. apply (step_preserves_halting _ _ E); eauto.
  intros.
  eapply IHT2. eapply T_App. apply typable_empty_t.
  eapply R_typable_empty. assumption.
  apply ST_App1. apply E.
  apply RRt'; auto.
Qed.
Lemma multistep_preserves_R' : \forall T \ t \ t',
  has_type empty t \ T \rightarrow (t ==>* t') \rightarrow R \ T \ t' \rightarrow R \ T \ t.
Proof.
  intros T t t' HT STM.
  induction STM; intros.
     assumption.
     eapply step_preserves_R'. assumption. apply r. apply IHSTM.
     eapply preservation; eauto. auto.
Qed.
```

35.5.2 Closed instances of terms of type T belong to $R_{-}T$

Now we proceed to show that every term of type T belongs to R_-T . Here, the induction will be on typing derivations (it would be surprising to see a proof about well-typed terms that did not somewhere involve induction on typing derivations!). The only technical difficulty here is in dealing with the abstraction case. Since we are arguing by induction, the demonstration that a term $tabs \ x \ T1 \ t2$ belongs to $R_-(T1 \rightarrow T2)$ should involve applying the induction

hypothesis to show that t2 belongs to $R_{-}(T2)$. But $R_{-}(T2)$ is defined to be a set of closed terms, while t2 may contain x free, so this does not make sense.

This problem is resolved by using a standard trick to suitably generalize the induction hypothesis: instead of proving a statement involving a closed term, we generalize it to cover all closed instances of an open term t. Informally, the statement of the lemma will look like this:

```
If x1:T1,...xn:Tn \vdash t: T and v1,...,vn are values such that R T1 v1, R T2 v2, ..., R Tn vn, then R T ([x1:=v1][x2:=v2]...[xn:=vn]t).
```

The proof will proceed by induction on the typing derivation $x1:T1,...xn:Tn \vdash t:T$; the most interesting case will be the one for abstraction.

Multisubstitutions, multi-extensions, and instantiations

However, before we can proceed to formalize the statement and proof of the lemma, we'll need to build some (rather tedious) machinery to deal with the fact that we are performing multiple substitutions on term t and multiple extensions of the typing context. In particular, we must be precise about the order in which the substitutions occur and how they act on each other. Often these details are simply elided in informal paper proofs, but of course Coq won't let us do that. Since here we are substituting closed terms, we don't need to worry about how one substitution might affect the term put in place by another. But we still do need to worry about the order of substitutions, because it is quite possible for the same identifier to appear multiple times among the x1,...xn with different associated vi and vi.

To make everything precise, we will assume that environments are extended from left to right, and multiple substitutions are performed from right to left. To see that this is consistent, suppose we have an environment written as ..., y:bool,...,y:nat,... and a corresponding term substitution written as ...[$y:=(tbool\ true)$]...[$y:=(tnat\ 3)$]...t. Since environments are extended from left to right, the binding y:nat hides the binding y:bool; since substitutions are performed right to left, we do the substitution $y:=(tnat\ 3)$ first, so that the substitution $y:=(tbool\ true)$ has no effect. Substitution thus correctly preserves the type of the term.

With these points in mind, the following definitions should make sense.

A *multisubstitution* is the result of applying a list of substitutions, which we call an *environment*.

```
Definition env := list (id \times tm). Fixpoint msubst (ss:env) (t:tm) {struct ss} : tm := match ss with | nil \Rightarrow t | ((x,s)::ss') \Rightarrow msubst ss' ([x:=s]t) end.
```

We need similar machinery to talk about repeated extension of a typing context using a list of (identifier, type) pairs, which we call a *type assignment*.

```
Definition tass := list (id \times ty).
```

```
Fixpoint mextend (Gamma : context) (xts : tass) := match xts with 
 <math>| ni| \Rightarrow Gamma  | ((x,v)::xts') \Rightarrow extend (mextend <math>Gamma \ xts') \ x \ v end.
```

We will need some simple operations that work uniformly on environments and type assignments

```
Fixpoint lookup \{X: \mathsf{Set}\}\ (k: \mathsf{id})\ (l: \mathsf{list}\ (\mathsf{id} \times X))\ \{\mathsf{struct}\ l\}: \mathsf{option}\ X := \mathsf{match}\ l\ \mathsf{with}
|\ \mathsf{nil} \Rightarrow \mathsf{None}\ |\ (j,x) :: l' \Rightarrow \mathsf{if}\ \mathsf{beq\_id}\ j\ k\ \mathsf{then}\ \mathsf{Some}\ x\ \mathsf{else}\ \mathsf{lookup}\ k\ l'
\mathsf{end}.
Fixpoint drop \{X: \mathsf{Set}\}\ (n: \mathsf{id})\ (nxs: \mathsf{list}\ (\mathsf{id} \times X))\ \{\mathsf{struct}\ nxs\}: \mathsf{list}\ (\mathsf{id} \times X) := \mathsf{match}\ nxs\ \mathsf{with}
|\ \mathsf{nil} \Rightarrow \mathsf{nil}\ |\ ((n',x)::nxs') \Rightarrow \mathsf{if}\ \mathsf{beq\_id}\ n'\ n\ \mathsf{then}\ \mathsf{drop}\ n\ nxs'\ \mathsf{else}\ (n',x):: (\mathsf{drop}\ n\ nxs')\ \mathsf{end}.
```

An instantiation combines a type assignment and a value environment with the same domains, where corresponding elements are in R

```
Inductive instantiation: tass \rightarrow env \rightarrow Type := | V_ni| : instantiation nil nil <math>| V_cons : \forall x \ T \ v \ c \ e, value v \rightarrow R \ T \ v \rightarrow instantiation \ c \ e \rightarrow instantiation \ ((x, T) :: c) \ ((x, v) :: e).
```

We now proceed to prove various properties of these definitions.

More Substitution Facts

First we need some additional lemmas on (ordinary) substitution.

```
symmetry in Heqe; apply beq_id_false_not_eq in Heqe.

35.6 MoreStlc: A Typechecker for STLC

The *has_type* relation of the STLC defines what it means for a term to belong to a type (in some context). But it doesn't, by itself, tell us how to *check* whether or not a term is well typed.

Fortunately, the rules defining has_type are syntax directed – they exactly follow the shape of the term. This makes it straightforward to translate the typing rules into clauses of a typechecking function that takes a term and a context and either returns the term's type or else signals that the term is not typable.

35.6.1 Comparing Types

```
First, we need a function to compare two types for equality...
Fixpoint beg_ty (T1 T2:ty): bool :=
  match T1, T2 with
  | \mathsf{TBool}, \mathsf{TBool} \Rightarrow
       true
  | TArrow T11 T12, TArrow T21 T22 \Rightarrow
       andb (beq_ty T11 T21) (beq_ty T12 T22)
  | _,_ ⇒
       false
  end.
   ... and we need to establish the usual two-way connection between the boolean result
returned by beq_ty and the logical proposition that its inputs are equal.
Lemma beq_ty_refl : \forall T1,
  beq_ty T1 T1 = true.
Proof.
  intros T1. induction T1; simpl.
    reflexivity.
    rewrite IHT1_1. rewrite IHT1_2. reflexivity.
Qed.
Lemma beq_ty_eq : \forall T1 T2,
  beq_ty T1 T2 = true \rightarrow T1 = T2.
Proof with auto.
```

intros T1. induction T1; intros T2 Hbeq; destruct T2; inversion Hbeq.

apply andb_true in H0. inversion H0 as $[Hbeq1 \ Hbeq2]$. apply $IHT1_1$ in Hbeq1. apply $IHT1_2$ in Hbeq2. subst...

35.6.2 The Typechecker

Case "T1=TArrow T1_1 T1_2".

Case "T1=TBool". reflexivity.

Qed.

Now here's the typechecker. It works by walking over the structure of the given term, returning either *Some T* or *None*. Each time we make a recursive call to find out the types of the subterms, we need to pattern-match on the results to make sure that they are not *None*. Also, in the *tapp* case, we use pattern matching to extract the left- and right-hand

sides of the function's arrow type (and fail if the type of the function is not TArrow T11

T12 for some T1 and T2).

```
Fixpoint type_check (Gamma:context) (t:tm) : option ty :=
  {\tt match}\ t\ {\tt with}
    tvar x \Rightarrow Gamma \ x
   | tabs x T11 t12 \Rightarrow match type_check (extend <math>Gamma \ x \ T11) t12 with
                                    Some T12 \Rightarrow Some (TArrow T11 T12)
                                    \downarrow \_ \Rightarrow \mathsf{None}
  | tapp t1 t2 \Rightarrow match type_check Gamma t1, type_check Gamma t2 with
                              | Some (TArrow T11 T12), Some T2 \Rightarrow
                                 if beg_ty T11 T2 then Some T12 else None
                               | \_,\_ \Rightarrow \mathsf{None}
                            end
   ttrue \Rightarrow Some TBool
    tfalse \Rightarrow Some TBool
   \mid tif x t f \Rightarrow match type_check Gamma x with
                             | Some TBool \Rightarrow
                                match type_check Gamma\ t, type_check Gamma\ f with
                                   | Some T1, Some T2 \Rightarrow
                                      if beq_ty T1 T2 then Some T1 else None
                                   | \_,\_ \Rightarrow \mathsf{None}
                                end
                             | \_ \Rightarrow \mathsf{None}
                           end
```

end.

35.6.3 Properties

To verify that this typechecking algorithm is the correct one, we show that it is *sound* and *complete* for the original *has_type* relation – that is, *type_check* and *has_type* define the same partial function.

```
Theorem type_checking_sound: \forall \ Gamma \ t \ T, type_check Gamma \ t = Some \ T \rightarrow has_type \ Gamma \ t \ T. Proof with eauto.
